To Camp Sevier, Greenville, S. C., base hospital, from Camp Sevier, Major CHARLES S. VENABLE, San Antonio.

To Camp Travis, Fort Sam Houston, Tex., for duty, Lieut. ROY L. AIGUIER, Dallas; from Corpus Christi, Capt. THOMAS P. POOLE, Eagle Lake.

To Camp Wheeler, Macon, Ga., base hospital, from New York City, Lieut. RALEIGH L. DAVIS, Big Springs.

To Fort Oglethorpe for instruction, from Camp Logan, Lieut. ELI. E. BROWN, Dallas.

To Fort Sam Houston, Tex., for duty, Capts. ISAAC MAYHUGH, Barstow; JOHN W. SNYDER, Childress; ARTHUR E. SWEATLAND, Nacogdoches; Lieuts. EZRA E. DICKASON, Brownsville; PERRY G. HAYS, Sipe Springs; JAMES A. MURRAY, Walnut Springs.

To New Haven, Conn., for duty, from Fort Oglethorpe, Lieut. IVY STANSELL, Sanderson.

To New York City, Cornell Medical College, for instruction in military roentgenology, and on completion *to Hoboken, N. J.*, base hospital, from Fort Oglethorpe, Capt. WILLIAM R. FICKESSEN, San Antonio.

To Philadelphia, Pa., for instruction, from Fort Oglethorpe, Lieut. CARL B. YOUNG, JR., Houston.

To Pittsburgh, Pa., Carnegie Institute of Technology, for instruction, and on completion *to his proper station*, from Fort Oglethorpe, Lieut. ST. JULIAN R. MURCHISON, Marshall.

Utah

To Camp Kearny, Linda Vista, Calif., for duty, from Camp Kearny, Capt. GEORGE H. CRUIKSHANK, Vernal.

Vermont

To Camp Dix, Wrightstown, N. J., base hospital, Lieut. JOHN W. HARVEY, St. Johnsburg.

To Camp Dodge, Des Moines, Ia., as division tuberculosis specialist, from Fort Riley, Capt. GEORGE L. BATES, Morrisville.

To Camp Upton, Long Island, N. Y., for duty, from Army Medical School, Lieut. LUTHER J. CALAHAN, Manchester Center.

To Hoboken, N. J., for duty, from Camp Dix, Major WILLIAM W. TOWNSEND, Rutland.

Virginia

To Fort McPherson, Ga., for temporary duty, Lieuts. LANDON E. STUBBS, Gloucester; ALBERT T. RANSONE, Hampton.

To Fort Oglethorpe for instruction, Lieuts. HAMIL S. SCOTT, Emory; ARTHUR H. DEEKENS, Lynchburg; from Fort Monroe, Lieut. SAMUEL M. FORD, Lebanon.

To Rockefeller Institute for instruction, and on completion *to Camp Pike*, Little Rock, Ark., base hospital, from Fort Oglethorpe, Lieut. JOHN O. BOYD, Roanoke.

To Army Medical School for instruction, Lieut. HARTWELL G. STONEHAM, Waverly.

To Boston, Mass., Harvard Graduate Medical School, for instruction [illegible] from Fort Oglethorpe, Lieut. CHARLES W. [illegible] N. J., for duty, from Camp Dix, Lieut. [illegible] chmond. Base hospital, from Fort Oglethorpe, [illegible] CARROLL, Rio Vista.

To Camp Greene, Charlotte, N. C., base hospital, from Camp Greene, Major GEORGE A. RENN, Norfolk.

To [illegible] Augusta, Ga., base hospital, from Fort Oglethorpe, Lieut. [illegible], Amherst.

To [illegible] *ston*, Jacksonville, Fla., base hospital, from Fort Oglethorpe, Lieut. THOMAS R. COLLIER, Hampton.

To Camp Sevier, Greenville, S. C., base hospital, from Atlanta, Lieut. EDWARD B. BROOKS, Chase City; from Camp Gordon, Lieut. LUC [illegible] Fort Monroe, Major LOMAX GW. [illegible] horpe, Capt. MINOR C. LILE, Univ [illegible], Norfolk; LEVIN F. MAGRU- DOI [illegible] iversity; from Fort Riley, Capt. HEN [illegible] University, Major WILLIAM H. [illegible]

T[illegible] Capt. HUGH S. MAHOOD, Nor [illegible] SBORNE, Clinch; ISAAC E. WOLFE, Coeburn; from Philadelph [illegible] POWELL, Roanoke; from Richmond, Lieut. [illegible], Richmond; from Camp Wheeler, Lieut. [illegible], Roanoke.

To Fort Riley, base hospital, [illegible], Lieut. CLIFFORD A. FOLKES, Roanoke.

To Hoboken, N. J., for temporary duty, from Fort Oglethorpe, Lieut. SAMUEL A. RHYNE, Norfolk.

To New York City, Cornell Medical College, [illegible] military roentgenology, and on completion *to H*[illegible], from Fort Oglethorpe, Lieut. JOSEPH T. [illegible]

Honorably discharged on account of phy[illegible] or to entrance into the service, Lieut. WILLI[illegible]

Washington

To Camp Lewis, American Lake, Wash., base hospital, from Camp Fremont, Lieut. IRVING M. LUPTON, Spokane; from Camp Lewis, Lieut. HARRY C. BLAIR, Tacoma.

To Portland, Ore., for duty, Lieut. WARREN B. PENNEY, Tacoma.

[illegible] *Barracks, Wash.*, for duty, from Camp Fremont, Lieut. [illegible] Seattle.

[illegible] Lieut. CARL O. LIND, Seattle.

West Virginia

To Camp American University, Washington, D. C., for duty, Lieut. STEPHEN W. BULL, Spencer.

To Camp Beauregard, Alexandria, La., base hospital, from Fort Oglethorpe, Lieut. LEROY J. BUTLER, Hansford.

To Camp Devens, Ayer, Mass., as member of the board examining the command for tuberculosis, from Fort Hancock, Capt. GEORCE H. BARKSDALE, Charleston.

To Camp [illegible] C., base hospital, from Fort Oglethorpe, Capt. [illegible], Hiawatha.

To Fort McDowell, Calif., for duty, from Fort Oglethorpe, Lieut. WALTER S. LINK, Parkersburg.

To Fort Oglethorpe for instruction, Capt. McRAE C. BANKS, Raleigh; Lieut. ERNEST J. WICHTERMAN, Masontown.

Honorably discharged, Lieuts. NOAH E. STEELE, Chauncey; MICHAEL P. LINK, Matewan.

Wisconsin

To Camp Grant, Rockford, Ill., base hospital, from Camp Dodge, Lieut. DONNE F. GOSIN, Green Bay.

To Camp Wheeler, Macon, Ga., as orthopedic surgeon, from Fort Oglethorpe, Lieut. BERNARD O. BENDIXEN, Kewaskum.

To Fort Oglethorpe for instruction, Capt. ANFIN EGDAHL, Menomonie; Lieut. CHARLES E. STOLZ, Milwaukee.

To Fort Riley for instruction, Lieut. CARLTON M. BEEBE, Sparta.

To Mineola, Long Island, N. Y., for duty, from Fort Riley, Lieut. HAROLD McM. HELM, Beloit.

To New Haven, Conn., for duty, from Fort Oglethorpe, Capt. MICHAEL R. WILKINSON, Oconomowoc.

Honorably discharged on account of physical disability existing prior to entrance into the service, Capt. CHARLES A. CRITCHLOW, Mellen.

Wyoming

To Chicago, Ill., for instruction, from Fort Riley, Lieut. ROBERT H. SAUNDERS, Kemmerer.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST; SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

CALIFORNIA

Hookworm in the Mines.—California is carrying on a systematic campaign against hookworm in the mines of the state. The *Bulletin* of the state board of health for March contains an article on sanitation in the mines and the prevention of hookworm. Illustrations and specifications for sanitary conveniences to be used in mines are shown.

Birth Control Literature Not Obscene.—Judge M. T. Dooley, of the United States District Court at San Francisco, handed down an opinion, March 18, in the case of A. Belinski, charged with having put into the mail some of Margaret Sanger's birth control literature. He holds that the statute penalizing the posting of obscene matter does not include birth control or similar literature.

Full-Time Health Officers.—The death rate of Palo Alto, the seat of Stanford University, is about half that for the state. The city has a population of 6,000 and employs a full-time health officer, to which fact the low death rate is attributed. Since 1911, according to the *Bulletin* of the state board of health for March, there have been no deaths of infants under 2 years of age from diarrhea or enteritis, whereas during the same period in all other parts of the state there were 5,528 deaths of infants under 2. At the beginning of 1918 there were three known cases of tuberculosis in the city. The cost of the health department for 1917 was $3,310, or 56 cents per capita.

CONNECTICUT

Society Endorses Board.—The New Haven Medical Society at its meeting, March 7, adopted resolutions endorsing the board of health of the city and stating that any attempt to curtail the budget of the board should be regarded as a public calamity.

Health Survey.—At the request of the mayor of Middletown and other public and semipublic officials and organizations, Prof. Charles E. A. Winslow of the Department of Public Health, Yale School of Medicine, assisted by David Greenberg and Ira D. Joel of the same department, made a survey of health and sanitary conditions and the administration of the health service of Middletown. The results and their recommendations have been printed in a well illustrated pamphlet with an introductory article by Professor Winslow. It was found that there is considerable room for improvement of conditions in the city, and the officials and organizations asking for the survey have pledged themselves to carry out as far as possible the committee's recommendations, of which there are about forty specifically set forth. One of the things in need of correction is the incidence of malaria, about 200 cases of which were treated during the year 1917.

HAWAII

Report of Board of Health for 1917.—The report of the president of the Hawaii Board of Health to the governor for the year ending June 30, 1917, indicates that health in the islands was good, as shown by a decrease of 442 in the number of deaths and 2,573 in the number of cases of contagious disease. Diarrhea and enteritis, tuberculosis in all forms and pneumonia lead in the causes of death. Interesting data are given with reference to sanitation, mosquito elimination, rat destruction and examination, medical school inspection, foods, insane and leper hospitals, tuberculosis, etc.

Medical News.—The board of medical examiners of the territory in 1917 lost one member by death, Dr. W. L. Moore, Dr. Grover A. Batten being appointed to succeed him.—— During the year ending June 30, 1917, 17 physicians were recommended for license, whose nationalities were as follows: American 10, Japanese 5, Chinese 1, Korean 1. On the date named there were 138 physicians in the territory licensed to practice, as follows: American 72, British 11, Japanese 44, Chinese 4, German 4, Portugese 1, Norwegian 1, Korean 1. By deaths and resignation, the number of physicians remains the same as during the previous year. The license of one

Japanese physician was revoked on account of "gross carelessness and manifest incapacity," according to the report of the board of medical examiners.——The president of the board of health, Dr. J. B. S. Pratt, attended the annual conference with Surgeon-General Blue of the Public Health Service in Washington, D. C., and also the conference of state and provincial boards of health of North America in April and May, 1917, making a full report to the governor of the work done at the conferences.

ILLINOIS

Will Require Practical Examinations.—The department of registration and education of Illinois has adopted the requirement that hereafter the examination for the license to practice medicine in Illinois will include practical examinations in pathology and bacteriology; surgery and gynecology; medicine, including pediatrics and neurology, and diseases of the eye, ear, nose and throat. These practical tests will be held at the Cook County Hospital, Chicago, immediately following the written examination.

Activities of the State Department of Health.—In the January number of the *Illinois Health News,* the bulletin of the department, a history is given of the legislation abolishing the old state board of health and creating the new department of health and the sloughing off of many duties not properly belonging to a health department, such, for instance, as the examination of applicants for license to practice medicine, midwifery, embalming, drugless healing, etc., which is now performed by the department of education and registration. The department now has a director and an assistant director, and the functions are classified under ten different divisions, which have been in operation since July, 1917. The service performed by each of these divisions is described in the bulletin, and the heads of each are named. There are five laboratories in different cities of the state—Springfield, Chicago, Mount Vernon, Urbana and Galesburg.

Chicago

Reconstruction Work.—Cripples in Cook County Hospital are being taught basket weaving, rug making, wood cutting and similar arts, in the manual arts department recently opened by the social welfare department of the hospital. A similar service for crippled soldiers will be rendered by the department under the direction of Miss Stesser. This instruction is undertaken as an economic measure, to offer an opportunity whereby the maimed and crippled may become self-sustaining.

INDIANA

Sanitary Meeting.—The annual convention of the Indiana Sanitary and Water Supply Association was held in Indianapolis, March 27 and 28. The membership of the association consists of mayors, waterworks superintendents, health officers and sanitary engineers.

Personal.—Dr. Harley W. Taylor, Rochester, suffered a fracture of four ribs and other injuries in a collision between a motor truck and the automobile in which he was riding, near Michigantown, March 20.——Dr. Anthony P. Witting, Evansville, was operated on at St. Mary's Hospital, Evansville, recently and is reported to be doing well.——Dr. James Y. Welborn, Evansville, has resigned from the board of trustees of the Vanderburg County Antituberculosis Society.

Inquiry Regarding Child Mortality.—At Gary, April 15, sixteen women agents of the federal Children's Bureau, began the second stage of their inquiry into conditions affecting children of preschool age. There are 4,622 mother of children under 7 years of age who will be visited for the purpose of discovering what adverse social, economic, and industrial conditions cause the death of large numbers of infants under 1 year of age. This inquiry will be supplemented by conferences which will begin about June 1, at which mothers of children under the age of 1 year will have an opportunity to consult a government expert on the care of their children.

IOWA

Meeting of State Medical Society.—The Iowa State Medical Society will meet at Fort Dodge, May 8, 9 and 10 for the 1918 session.

Personal.—The drugstore of Dr. U. S. Rogers, Washta, was destroyed by fire, March 18.——Dr. James B. Rogers, Independence, has been appointed bacteriologist at the Cincinnati Municipal Tuberculosis Sanatorium, succeeding Dr. Johannes Hermanies, Chicago, resigned.

Reporting of Venereal Disease.—The city physician of Davenport has recommended to the board of health that an ordinance be passed requiring that a report be made to the board of all cases of venereal disease. The recommendation was referred to the Scott County Medical Society for its consideration.

Miscellaneous.—At Mount Pleasant the local board of health passed a resolution recommending, for the approval of the state board of health, a plan of chemical or other treatment of industrial sewage from creameries, slaughter houses, canning factories, etc., before being discharged into the sanitary sewers.——At Rock Rapids the board of education has secured the services of a trained nurse to help to stamp out scarlet fever which has been prevalent in the schools the greater part of the winter.

Hospital News.—The mayor and city clerk of Boone have been instructed by the city council to enter into an agreement with Boone County to build a detention hospital on a lot belonging to the county. The county will assure one half of the cost.——Improvements to cost about $10,000 are to be made at the Santa Fe Hospital, Fort Madison. A separate ward is to be established for Mexican laborers.——A delegation from Grinnell recently visited Atlantic to inspect the new hospital. It is their intention to erect a similar hospital in Grinnell.

KENTUCKY

Health Board Not to Move.—After inspection of the present quarters of the state board of health at Bowling Green, and the proposed sites of Frankfort and Lexington, the house committee of the legislature has reported that in its opinion the immediate removal of headquarters will be inadvisable.

Merger of Board.—March 27, Governor Stanley signed the bill merging the state tuberculosis commission and the hotel inspection department with the state board of health. The bill creates a new state board of health to be composed of ten members, of whom all but one are to be appointed by the governor.

Personal.—Dr. Addie M. Lyon, county health officer at Sandy Hook handed in his resignation, giving his reason the opposition he had encountered in enforcing the quarantine regulations of the state board of health. The resignation was not accepted. Dr. Lyon was urged to continue his services.——Dr. L. A. King has been appointed local director of free dental service in the fourth district, comprising Henderson, Union, Hopkins and Webster counties.——Dr. Jesse I. Whittenberg, county health officer for Jefferson County, has resigned, and a successor will soon be named. The salary of this official was reduced from $3,000 to $2,500 per year by the new board of county commissions several weeks ago. Dr. Clarence H. Harris, a member of the county board of health, has been elected county health officer pro tem.——Dr. David C. Morton has resigned as a member of the board of directors of the Louisville Municipal Tuberculosis Sanatorium and has been succeeded by Mr. Isaac Hilliard.——Dr. Argus D. Willmoth, Louisville, has been appointed a member of the state tuberculosis commission.——Drs. Henry Enos Tuley, George S. Coon, Eugene Y. Johnson and George A. Hendon have been sworn in as members of the board of directors of the Louisville Municipal Tuberculosis Sanatorium.

Miscellaneous.—The annual meeting of the health officers of the state which convenes in Louisville, May 1, for a three-day session, was arranged for at the meeting of the state board of health, March 20. At this meeting the meningitis situation in the state was discussed, and the Flexner serum treatment was approved. It was reported that out of eighteen cases of meningitis at Berea, there were no deaths.——The meningitis situation at Glasgow has improved, following the investigation by Dr. Lillian H. South, Bowling Green, bacteriologist of the state board of health, and Dr. J. Paul G. Prebles of the United States Public Health Service.——Dr. W. H. Dunn, a chiropractor in Louisville, March 1, was tried in the criminal court for practicing medicine without a license. His defense was that he did not administer medicine and did not practice surgery. Dunn was formerly fined $50 by the jury of the charge.——A beautiful service flag was raised at the Jewish Hospital in honor of nine nurses who have joined the Army Red Cross. Capt. Virgil E. Simpson of Base Hospital Unit No. 40, now at Camp Zachary Taylor, made the principal address.——A service flag bearing forty stars has been unfurled at the University of Louisville, medical department, in honor of those members of the teaching staff who are now actively in the service of the Medical Corps of the Army.

LOUISIANA

Personal.—Dr. Henry B. White, Gueydan, has resigned, as a member of the state board of health.

Health Officer Barred from Plant.—On March 20, President Oscar Dowling of the state board of health, with two inspectors, was refused admission to the shipbuilding plant of the United States Shipbuilding Board at Slidell.

New Hospital Unit.—Mrs. John Debeit, New Orleans, has contributed $100,000 toward the initial equipment of a base hospital unit which is to be sent to Italy under the directorship of Major Joseph A. Danna, New Orleans. It will be known as the Loyola Unit.

Hair Brush Abolished.—On account of the menace of the public hair brush, which is said to be responsible for 90 per cent. of baldness, as well as being the conveyor of skin infections, the Louisiana State Board of Health has prohibited the use of the hair brush in barbershops, hair-dressing establishments and other public places.

Constructive Health Recommendations.—In a report made by the bureau of venereal diseases to the state board of health, March 22, the following recommendations were made: compulsory treatment of venereal diseases in all their phases; a certificate of good health by a physician as prerequisite to the issurance of marriage licenses, and the establishment of an arsphenamin factory at Alexandria. The report was adopted with slight amendments. Dr. Dowling was authorized to call for plans for laboratory buildings at New Orleans and Alexandria.

MARYLAND

Personal.—Dr. James W. Magruder, Baltimore, who has resigned as secretary of the federated charities to become associated with the Maryland War Commission on Camp Activities, was tendered a farewell dinner by the Baltimore Social Service Club, March 27.

Sanitary District.—A bill has been introduced into the house creating a sanitary district in Baltimore County, consisting of a wide belt of territory encircling the city of Baltimore to include Sparrow's Point, Back River, Towson, Catonsville and Relay. The plan must have the approval of the state board of health.

Would Revise State Law.—A bill has been introduced in the house by Delegate Benson of Baltimore County, which revises the state laws, regulating the practice of medicine, surgery and osteopathy and creates a state board of examiners to consists of eleven members, eight of whom are to be selected by the Medical and Chirurgical Faculty of Maryland, two by the Maryland State Homeopathic Medical Society and one by the Maryland Osteopathic Association.

Patients Leave Fort McHenry.—Departing in units of various sizes, 174 men were transferred, April 12, from the U. S. Army General Hospital No. 2 at Fort McHenry to government hospitals in other cities. Of the number leaving, eight were officers and the remainder enlisted men. The largest unit was sent to New Haven, Conn. Others went to Lakewood, N. J.; Fort McPherson, Ga.; the Walter Reed General Hospital, Washington, D. C., and Cape May, N. J. With the department of these men, only eight patients were left at the fort, but others are expected shortly.

Physical Training for Schoolchildren.—One of the small but important bills recently passed by the general assembly of Maryland provides for physical education and training in the public schools. This bill was introduced at the request of Dr. William Burdick, director of the public athletic league. It directs that physical training shall be given the pupils in all public schools of the state and in all schools aided or maintained by the state. In the elementary public schools this is to consist of at least fifteen minutes on each school day and one hour outside the regular classroom work in each school week. In public high schools, the period of physical training is to be at least one hour in each school week and two hours of directed play and athletics for all pupils outside of the regular classroom work in each week.

MASSACHUSETTS

Miscellaneous.—Harvard has voted certificates of honor to every member of the university who gives up his studies to enter either branch of the service.

License Revoked.—The Board of Registration in Medicine of Massachusetts has, it is reported, suspended the license of Dr. Joseph M. Tessier, New Bedford, to practice in the state.

Harvard Appoints New Professors.—Assistant professorships in medicine and surgery, etc., were recently filled in Harvard as follows: Drs. Howard A. Lothrop and Hugh Cabot, in surgery, Worth Hale in pharmacology, Benjamin L. Ragle, in medicine, and Robert L. De Normandie in obstetrics.

Personal.—Dr. Morton Prince, Boston, has been given a decoration by the Emperor of Japan.——Dr. J. Armand Bedard of Lynn has arrived in France.——Dr. William H. McBain, associated medical examiner (coroner) of Malden and Medford districts, has been appointed city bacteriologist of Malden, succeeding Dr. Clarence H. Staples, resigned.——Dr. LeRoy A. Woodward has been appointed surgeon for the outpatient department of the Worcester City Hospital.

Hospital at Holden.—In order that the private hospital at Holden, which has been in operation for the past three years, might not be discontinued, as was contemplated, the citizens organized a corporation for the purchase of the buildings and equipment of the Holden Cottage Hospital, and it will now be run under new management for the benefit of the town. Among the physicians connected with its staff and management are Drs. Walter H. Welch and Frank H. Washburn.

MICHIGAN

Personal.—Dr. Lyman S. Crotser, Petoskey, fell, March 25, fracturing his hip. He is under treatment at a local hospital.

Sterilization of Defectives Unlawful.—The act of the Michigan legislature of 1913, which authorized the sterilization of mentally defective inmates of public institutions was declared unconstitutional by the supreme court of the state, March 28.

Sanatorium Annex for Soldiers and Sailors.—At a special meeting, March 22, the trustees of the Detroit Tuberculosis Sanatorium ordered the erection of a building to house soldiers and sailors invalided on account of tuberculosis. The new unit will cost $10,000 and will accommodate twelve patients.

Votes for Municipal Medical School.—The board of education of Detroit has voted in favor of taking over the Detroit College of Medicine and Surgery and of converting it into a municipal institution. The trustees of the college agree to turn over to the city, free of debt, the buildings and equipment of the college which are valued at approximately $160,000. The proposal provided that the present faculty should resign and that a new faculty be appointed by the board.

NEW YORK

Medical Scholarship for Women.—A scholarship in medicine for a college woman has been endowed by Mrs. E. T. Stotesbury and placed in charge of Dr. Elizabeth Thelberg of Vassar College. The gift was made because of the reported lack of physicians due to the war.

Gift for Women Students.—Columbia University reports a gift of $5,000 from an association of women physicians, which with gifts of $18,000 received from other donors will be expended for a new building for the use of women students. Additional laboratories will also be provided.

Red Cross House at Base Hospital No. 1.—The Red Cross House in connection with United States General Hospital No. 1, Gun Hill Road and Bainbridge Avenue, was opened, March 30. This is the first of a number of similar houses now being built by the American Red Cross at the larger base hospitals. It is intended as a lounging and rest-room for convalescent soldiers and as an administration center for the Red Cross field director, through whom relatives may obtain accurate information as to the welfare of the patient. These houses contain many features which will contribute to the comfort of the soldiers. There is a solarium, a women's reception room, billiard rooms, committee rooms, an assembly room and a diet kitchen.

Summer Training School.—The training of teachers for teaching the feebleminded, as well as special classes in the public schools, will be carried on in the Rome State Custodial Asylum during the summer, from July 1 to July 27. The course will be open to graduates of normal schools and teachers' training schools. The school is supported by the state and there will be no charge for tuition, but a charge of $20 for board and lodging in the institution. The asylum cares for 1,550 feebleminded and has fourteen teachers and 200 officers and employees. The work will be by lectures and practical work among the inmates. There are many vacancies for this class of teachers, who receive higher pay teachers in general primary work. Information obtained from the superintendent.

New York City

Zionist Hospital Unit Ready.—A hospital unit, equipped at a cost of $259,000, by the women's branch of the Zionist movement, will sail for the Holy Land in a few days. The unit has a personnel of forty-one of whom fifteen are physicians. A hospital in Jerusalem has already been placed at the disposal of the unit.

Personal.—Dr. John Dorning has been reappointed by Mayor Hylan to the New York City Board of Inebriety.——Dr. Anna I. von Sholly, who is in service with the Women's Overseas Hospitals, was recently caught in the zone of fighting, and, at latest reports, was still cut off from her headquarters in Paris. She had gone into the fighting zone to prepare a new hospital for occupation.

New Clinic for Rehabilitation of Injured Soldiers.—Through the beneficence of an anonymous donor, New York is to have a new clinic and hospital devoted to the functional reeducation of maimed military men and civilians. The institution is to be opened within six weeks and will occupy a part of the plant formerly used by the New York Infirmary for Women and Children at Stuyvesant Square and Fifteenth Street. The institution is to be known as the New York Clinic for Functional Reeducation of Disabled Soldiers, Sailors and Civilians. The president of the organization is Dr. W. Gilman Thompson.

Health Department Undergoing Investigation.—In compliance with an order from Mayor Hylan an investigation of the health department is being conducted by the commissioner of accounts in cooperation with the civil service commissioner. The health commissioner, Dr. Lewis J. Amster, is sitting with these investigating bodies. The investigation is being made with a view of correcting alleged violations of the civil service law and of removing from the payroll the names of persons found to be illegally employed and reducing to their proper status all persons who are enjoying the emoluments of grades higher than those for which they took promotion tests. At a conference with the public health committee of the New York Academy of Medicine, Dr. Amster explained that he wished to determine whether the directors of the seven bureaus of the health department held their places legally under the charter and whether these bureaus were under proper authority of law. At the stated meeting of the section on pediatrics of the New York Academy of Medicine, resolutions were adopted protesting against the proposal to abolish the bureau of child hygiene. These resolutions were presented to the executive committee of the public health committee of the academy to emphasize the vital importance of the bureau to the welfare of the city.

OHIO

Chiropractor Convicted.—Torizo Tanaka, a Japanese chiropractor, who was conducting an elaborate office at Cleveland, and who had the legal backing of the combined chiropractic interests, was convicted of practicing medicine and surgery without a license and sentenced to thirty days in the workhouse and fined $250 and costs.

Miscellaneous.—On account of the scarcity of men physicians, Dr. William H. Peters, chief medical inspector of the board of health of Cincinnati, has announced that he has recommended that three women be appointed as district physicians. Waiving its rule against nonresident physicians, the board of health has appointed Dr. A. M. Freund, Appleton, Wis., as a member of the health staff.

Personal.—Dr. William B. Bryant, Dayton, has resigned from the city staff. He has been succeeded by Dr. Leo R. Courtright.——Dr. John E. Monger, Greenville, state registrar of vital statistics spoke on the value of vital statistics as an index to community health, before the March meeting of the Clark County Medical Society.——Dr. H. H. Goddard, of Vineland, N. J., who has been appointed head of the department of juvenile research of the state board of health, will report for duty, May 1. The salary is $7,500 a year.——Dr. Sara E. Stevens, Boston, visiting in Xenia early in March, will spend a year in Hawaii.——Dr. Virgil E. Hutchens, New Antioch, was operated on for appendicitis in the Hale Hospital at Wilmington, March 22.——Dr. George W. Wire, health officer of Wilmington, has resigned and Dr. Frank A. Peelle, Wilmington, has been appointed in his place.——Drs. Rollin M. Schwartz, Columbiana; Edwin W. Mitchell, Cincinnati, and Andrew W. Schiller, Salem, have been certified from the civil service list for appointment as health officers at Salem.

PENNSYLVANIA

Sanatorium Becomes a War Hospital.—The Markleton Sanatorium in Somerset County has been taken over by the government for a war hospital.

The Pennsylvania Association for the Blind.—The Pennsylvania Association for the Blind has offered to the members of the senior class of the medical school, University of Pittsburgh, a prize for the best essay of 2,000 words on the prevention of blindness. The committee on award consists of some of the best known oculists and laymen in western Pennsylvania. It is expected to make this offer annually to each senior class. The prize will be $100.

License Revoked.—April 10, the Pennsylvania Bureau of Medical Education and Licensure revoked the license of Dr. Nathan C. Kartub of East Vandergrift, who had pleaded guilty and was convicted "of murder in the second degree." The bureau also revoked the license of Dr. Frank J. Kenney, who had been convicted and plead guilty on a charge of larceny. According to reports, Frank J. Kenney was arrested in November, 1917, in connection with a diploma mill scandal in Boston, pleaded guilty to an indictment charging him with larceny and was sentenced "to six months in the common jail."

Conference of Industrial Physicians.—The sixth conference of the Industrial Physicians and Surgeons of Pennsylvania and the second meeting of the Pennsylvania Chapter of the American Association of Industrial Physicians and Surgeons were held jointly in Harrisburg, April 16. The meeting assembled under the direction of the Pennsylvania Department of Labor and Industry in the hall of the house of representatives. Among the questions taken up were those relating to health hazards to women as a result of war emergency work and the reconstruction and rehabilitation of the injured and diseased in industry as well as in war. Dr. Francis D. Patterson, chief of the division of hygiene and engineering of the department of labor and industry, presided at the sessions which lasted from 9 a. m. to 6 p. m. Among the speakers were Dr. Loyal A. Shoudy, chief surgeon in the Bethlehem Steel Company; Dr. Edward Martin, Philadelphia; Major Joseph C. Bloodgood of Baltimore; Dr. Alfred Stengel, professor of medicine at the University of Pennsylvania, and Dr. John B. McAlister, past president of the medical society of Pennsylvania.

Personal.—Dr. Lowell M. Gates of Scranton is president of the New American Bank of Commerce which opened in Scranton, March 16.——Dr. Roger R. Rupp, Lehighton, has succeeded the late Dr. John W. Luther as chief surgeon of the Palmerton Hospital.——Dr. John A. Klump, Williamsport, succeeds Dr. Albert F. Hardt as member of the Middle Judicial District Exemption Board of Appeals.——Dr. Edward S. Dougherty, Ashley, was severely injured recently when an automobile in which he was riding crashed into a telegraph pole.——Dr. John G. Wilson, Montrose, has been appointed resident physician at the Hillside Sanitarium for Mental Defectives and Indigents, near Scranton.——Dr. James W. Harper, Forest Grove, has accepted a surgeonship with the Westinghouse Electric Company, Pittsburgh.——Dr. Irving Gellman, a native of Odessa, Russia, who is a graduate of the College of Physicians and Surgeons of Boston and who has done a great deal of tuberculosis work in connection with the Montefiore Home, Bedford Hills, N. Y., and with the Minnesota State Sanatorium, has been appointed resident physician to the state sanatorium for tuberculosis at Hamburg.

Philadelphia

New Section of College of Physicians.—The College of Physicians has organized a section on industrial medicine and public health, which will hold meetings in October, December, February and April of each year.

Medical Club Reception.—April 19, a reception was tendered to Rear-Admiral J. M. Helm, U. S. Navy, Commandant, Fourth Naval District, and Rear Admiral Benjamin Toppan, U. S. Navy, Commandant, Philadelphia Navy Yard, at the Bellevue-Stratford Hotel, by the Medical Club of Philadelphia.

Personal.—Drs. Edward A. Mallon and Max F. Herrman have been appointed chief visiting physicians to St. Joseph's Hospital.——Dr. William E. Quicksall has been appointed laryngologist to St. Joseph's Hospital.——Dr. George A. Knowles has been appointed by Governor Brumbaugh, trustee for the state hospital, Norristown.——Dr. Annie J. Gardner Young has recently been appointed resident physician in the Pennsylvania State Sanatorium for Tuberculosis at Hamburg.

RHODE ISLAND

First Aid and the Medical Practice Act.—The *Bulletin* of the Rhode Island State Board of Health calls attention to the violation of the medical practice act by manufacturing plants which allow the "first aid" treatment applied by an attendant who is not a physician to suffice in case of injuries to employees. It says it is absurd to have strict regulations regarding the practice of medicine and the licensure of physicians and then permit the treatment of dangerous wounds by a nurse or other nonqualified person.

TEXAS

Nurses Association Organized.—At Port Arthur, April 1, the Graduate Nurses Association of Port Arthur and vicinity met and dissolved to form the Jefferson County Nurses Association, with the idea of becoming affiliated with the state nurses association. Officers were elected.

VIRGINIA

Miscellaneous.—Announcement has been made of, and bids asked for, the construction of a modern hospital corps school at the Hampton Roads naval base. The structure will be of brick, 156 by 80 feet, three stories high and will be provided with laboratories and all modern facilities for teaching purposes. The new unit memorial hospital for colored patients, now under construction at Richmond, will be seven stories high, will be fireproof, will have large sun porches on every floor, and will be a completely designed and equipped modern hospital, which may be operated in connection with the other units of the hospital or independently. The building is of brick with ornamental limestone trimmings.——The state legislature has voted to increase the appropriation for community sanitation and medical inspection conducted by the state board in connection with the International Health Board from $7,200 to $15,000. Under the stimulus of this work, a number of counties have now employed full-time health officers, and it is proposed that the citizens of the state should furnish an additional sum of money equal to that appropriated by the two bodies named for the purpose of extending the work.——Steps have been taken by Health Officer Roy K. Flannagan of Richmond to carry out the plans of the federal health service in combating venereal diseases.——At Norfolk, the county board of health, March 7, adopted ordinances prohibiting the pollution of the bay which is used for bathing purposes. This will require the cottage communities at Ocean View, Willoughby Beach and on the bay side to install plumbing and waste disposal arrangements. An ordinance was also adopted providing for the regulation and sale of meats and foods in the county, as well as for their preparation. Ordinances requiring the reporting of communicable diseases and regulating vice for the protection of men in the service were also passed.——Dr. Mosby G. Perrow, health officer of Lynchburg, reports that, during the last twelve months, at least fifty letters have been received at the health office asking for the date of birth of former citizens of Lynchburg. These letters, which could not be satisfactorily answered, have come from New Zealand, Australia, South Africa and from many places in this country. There were 740 births reported in 1917, but the health officer believes that at least 100 were not reported. Reporting of births began in 1910 and has been steadily improving.——The Richmond Antituberculosis Association has rejected the proposition of the city health department to place the association's nurse under the direction of the health department.——Governor Davis has signed a bill passed by the legislature amending the health law in regard to the appointment of local boards of health throughout the state.——The bill for an increase of salary for the state commissioner of health, Dr. Ennion G. Williams to $5,000 a year has been vetoed by Governor Davis. He recommends that the salary be made $4,000.——Richmond, during 1917, had the lowest death rate in its history, 16.92, and also the lowest typhoid death rate, 6.97.——Among the health bills passed by the present session of the legislature and signed by Governor Davis are bills to provide for public health nursing and medical inspection of schoolchildren.——A bill for the compulsory use of the prophylactic treatment to prevent ophthalmia neonatorum has been passed by the state legislature. The prophylactic will be furnished free by the state board of health.

CANADA

Personal.—Capt. Robert S. Armour, R. A. M. C., Campbellford, Ont., has been mentioned in despatches for meritorious work in East Africa. He is a graduate in medicine of the University of Toronto, 1915. He is at present in charge of a base hospital in the East African expeditionary force.——Lieut.-Col. Henry D. Johnson, Charlottetown, P. E. I., is in Toronto to look for a site for new medical stores. He returned from overseas a short time ago.——Dr. J. McKelvey Bell, Eufaula, Alta., director of medical services for the Invalided Soldiers' Commission, is in Toronto to talk over the affairs of that body with local representatives. It is likely that Capt. Edward Ryan, Kingston, will be continued in charge of this district.——The rank of surgeon-general has been abolished in Canada, and in the future the officers who have been known by this title will be addressed as either lieutenant-general or major-general.

GENERAL

American Public Health Association.—The American Public Health Association meeting for 1918 will be held in Chicago, October 14 to 17. The central theme of the meeting will be "The Health of the Civil Population in War-Time."

To Standardize Hospitals.—At a recent meeting of the Board of Trustees of the American Medical Association, funds were appropriated to permit the Council on Medical Education to extend its work of standardizing and listing such hospitals as, on investigation, shall be found in position to furnish acceptable internships for medical graduates. In 1914 the Council issued a list of such hospitals which was revised and reissued in 1916. Another revision will appear this summer.

Fatigue and Communicable Diseases Among Sailors.—In an investigation into the prevalence of communicable diseases by the division of sanitation of the bureau of medicine and surgery of the Navy Department, it was decided that fatigue is a factor in the spread of these diseases, and that "the attempt to make a sailor too rapidly is to invite disaster." This has been shown and is the subject of comment in the report comparing thoroughly seasoned men and recruits at the various training stations.

Change in National Institute.—The National Medical Institute of Mexico, founded in 1890 for research on and exploitation of the flora, fauna and climatology and geography of Mexico has been transformed into the Institute of General and Medical Biology by a recent decree. The institute has been engaged in the study and classification as well as the action of native plants, among them being axocopaque, or native wintergreen; yoloxochitl, which has action resembling that of digitalis; candelilla, which was said to have antisyphilitic action, an assertion which on investigation was found not to be true, though the plant has proved an important source of wax; and various other plants with diuretic and purgative action.

Early Graduation.—As a result of the agitation a year ago for the adoption of the continuous session for medical students, several schools provided that the senior session should begin in the summer of 1917 immediately following the class of the junior year, by which plan those students were graduated in February of the present year, instead of in June. The schools thus far reporting are Bowdoin Medical School, Portland, Me.; Columbia University College of Physicians and Surgeons, New York; Fordham University, School of Medicine, New York; University and Bellevue Hospital Medical College, New York; Tufts College Medical School, Boston, and St. Louis University School of Medicine, St. Louis. Rush Medical College, Chicago, and Leland Stanford Junior University School of Medicine, San Francisco, have the quarter system under which the sessions are continuous.

Conference on Social Work.—The National Conference of Social Work will hold its forty-fifth annual session at Kansas City, Mo., from May 15 to 22. Among the themes of papers and addresses on the program and topics for discussion are the care of convalescents, medical inspection of schools, public health nursing, hospital social service, nutrition, health centers, a national program of infant welfare, national salvage of the handicapped, preparing the soldier incapacitated by nervous or mental diseases for return to civil life; this last topic is the subject of discussion by Major Richard Hutchings, M. R. C., U. S. War Department, Washington, D. C. "Types of After the War Problems," by E. E. Southard, director of the state psychopathic hospital, Boston, is the topic discussed by C. Macfie [illegible] Phipps Psychiatric Clinic, Johns Hopkins [illegible] The "Care of the Feebleminded: Results and Significance of Mental Hygiene Work in the Army," to be handled by Dr. Frankwood E. Williams, medical director of the National Committee for Mental Hygiene, New York City, is a further topic of interest to the profession. Under public agencies and institutions there will be a discussion of private and state hospitals, sanatoriums, almshouses and jails. Infant mortality and Miss Julia Lathrop's efforts to save 100,000 babies this year out of the 300,000 whose lives needlessly have been lost each year is another topic that will be discussed.

CENTRAL AND SOUTH AMERICA

School of Preventive Medicine at Havana.—Dr. Pazos, of the public health service of Cuba, is agitating for the organization of a school of preventive medicine to train a corps of expert hygienists at Havana. The medical organizations of the country are sustaining his appeal.

Training School for Nurses in Costa Rica.—The *Gaceta Medica* of Costa Rica states that last year the medical department of the University of San José, Costa Rica, founded a training school for nurses. The school is in charge of Prof. B. Hernandez. Prof. C. Pupo was dean of the medical school last year. Prof. E. Rojas is the present dean.

Pedagogic Congress in Colombia.—A gathering of teachers, physicians, school inspectors and others was held recently at Bogota to discuss subjects connected with child welfare. The faculties of medicine, law and engineering of the university were prominent in the debates, and the resolutions adopted by the gathering call on the government for a number of promising reforms.

Death of Castilla.—The republic of Colombia is mourning the recent death of Dr. R. R. Castilla, a prominent physician who took a leading part in medical and civic matters, serving as chief of the public health service, editor of the *Gaceta Medica,* and organizer of the annual gatherings of medical men. He planted the first rubber plantation and cinchona plantation in the country, introduced coffee plantations and the cultivation of the potato in regions previously deemed incapable of raising them, and did much to raise the standard of the stocks of horses and cattle in the country and open up the mineral springs. He received his medical training in France and remained to practice medicine at Paris for a number of years. Among his publications was one on a sign of valvular stenosis. The *Repertorio* of Bogota comments that the 80 years of his life were crowded with energy and service.

Medical Congress of Colombia.—The third national gathering of the physicians of the Republic of Colombia was held recently at Cartagena. Among the numerous progressive resolutions adopted were some to the effect that the fight against tuberculosis requires the cooperation of parents, teachers and clergy besides official state support and the work of physicians, dentists and veterinarians. Other resolutions were that a certificate as to health conditions should be required in renting a house, and that the physician should persuade the head of the household to notify the authorities when there is a case of tuberculosis in the family, the physician thus respecting professional secrecy while accomplishing the desired notification. Another resolution appealed to the government to supply the drugs to cure tropical anemia, either gratuitously or at cost. It was also voted that the local authorities should take the necessary prophylactic measures. Other measures on which the state was urged to take action were the foundation of institutes of toxicology in the different centers of population, study of the great question of immigration, legislation to protect the public against unqualified practitioners of medicine, appointment of medical school inspectors, and free dispensaries for venereal diseases. The final resolution advocated the organization of the profession along the lines that work well in other countries.

FOREIGN

Miss Stern Appointed Professor at Geneva.—Privatdozent Lina Stern has been appointed professor extraordinary of physiologic chemistry at the University of Geneva.

Water-Bed Pavilion at Vienna.—The *Nederlandsch Tijdschrift* mentions that the Allgemeines Hospital at Vienna has equipped one pavilion with water-beds. There are fourteen rooms, each with from two to four water-beds, 100 water cushions, and 300 air cushions. It is said that many of the wounded and other patients who could find no relief before have been materially benefited by these water contrivances.

The Medical Service of the Portuguese Troops in France.—The *Medicina Contemporanea* relates that there are now nine Portuguese ambulances at the front. Several are advanced surgical stations. One, from last August to date of writing had had 2,738 operative cases. The Portuguese force has had 442 men killed, including six officers and nine men succumbing to gassing; 111 have been disqualified by sickness.

Prize for Work on Physical Science.—The *Gazzetta degli Ospedali* says that the Royal Academy of Sciences of Turin, Italy, has announced a prize of 26,000 lire ($5,200), to be awarded for the most remarkable and most celebrated work on any of the physical sciences published in the four years ending Dec. 31, 1918. The prize fund is a bequest from a senator of the realm, T. Vallauri. Competition is open to Italian and foreign scientists, and the term "physical sciences" is to be taken in the broadest sense.

Typhus in Portugal.—The city of Porto is suffering from an epidemic of typhus. Three hundred and fifty-two cases with twenty-three deaths were reported in the week ending March 5. This number is 148 less than the cases of the preceding week, but since then the number has risen again. Prof. R. Jorge is in charge of the campaign against the disease, and energetic measures are being taken to stamp out the epidemic. Scattered cases were reported elsewhere the same week, one in Lisbon. Typhus occurs nearly every year at Lisbon. Only twelve years have passed since 1882 without from one to ten cases of typhus at Lisbon, according to the *Medicina Contemporanea.*

The French Medical Journals and the War.—Some statistics have recently been published showing that of the 345 medical and other scientific journals published in France before the war, about 270 have suspended publication. Others have changed from weekly to a monthly issue and others issue only four numbers a year. The total quantity of the paper used by them now does not amount to more than 35 tons a month, less than half that used daily by a newspaper. The important discoveries and experiences of the war and the lessons from them have been spread broadcast by the medical journals, so that surgeons and physicians have been able to keep abreast of progress and thousands of lives have been saved. The organized medical press in France is pleading with the authorities for special concessions during the period of the prevailing scarcity of paper, but no heed has been paid the appeal as yet.

Deaths in the Profession Abroad.—**M. S. Bombin,** a leading syphilologist of Madrid, aged 71.——**J. S. de Figueroa** of Barcelona, editor of the *Gaceta Medica Catalana* and inspector of the public health service, aged 32.——**N. Granes** of Madrid, aged 70, editor of the *Progresos de la Clinica.*——**C. Ruata,** formerly professor of materia medica at the University of Perugia, author of numerous works on hygiene and public matters and also of works denouncing vaccination against smallpox. He was president of an international antivaccine society.——**P. Imbriaco,** aged 72, long a medical inspector in the medical department of the army and president of the Scuola di applicazione de sanita militare, located at Florence. He published a number of works on war surgery and the effects of projectiles.——The *Nederlandsch Tijdschrift* reports the death of Prof. **O. v. Angerer** of Munich, aged 68, author of numerous works on surgical questions and since 1917 editor of the *Zeitschrift für aerztliche Fortbildung.* He was called to the chair of surgery at the University of Munich in 1885.

PARIS LETTER

Paris, March 14, 1918.

Work of the Medical Department of the French Army at the Front

At the meeting before the last of the Académie de médecine, Dr. Sieur, medical inspector, showed that considerable progress had been made by the Service de Santé since the beginning of the war and detailed the work that this service is doing at the present time. The wounded are being brought in early. Not more than from four to six hours elapsed between the time of wounding and the arrival of the patient at one of the advanced ambulances. More than this, whenever it is possible, advanced first aid posts are established where extremely urgent operations can be done. In order to give such immediate care as is necessary in these cases, advanced ambulances have been organized, where, during offensive action, wounds of the soft parts can be treated, as well as the recuperable and those who cannot be transported, and where the sorting of the wounded may be done with a proper regard for their distribution to the evacuation hospitals and certain special formations farther back.

In the evacuation hospitals, the hospitalization quarters are organized adjacent to the quarters for the evacuable. It is in these quarters that the surgical automobile ambulances have been installed, where cases of head, chest and abdominal wounds can be treated with much dispatch. In short, if the condition of the wounded permits it, only fracture cases are sent to the special hospitals established farther back behind the lines. The evacuation hospitals, one for each army corps, are arranged to receive the wounded who are sent to them directly by the receiving posts and by the advanced ambulance groups. In case the admissions to the hospital are greater than the number that the hospital can take care of, there have been established in the zone of the *étapes* hospitals known as *hôpitaux de liaison chirurgicale,* where the postponed suturing and the secondary suturing can be done on those patients whose wounds have been dissected free of damaged tissue, but not sutured, in the front line formations.

Because of this arrangement it is now possible to secure primary wound healing even in those cases which heretofore have been regarded as most grave. The results obtained are excellent. Dr. Sieur has been able to restore to the army 78 per cent. of the wounded after a hospital stay of not more than twenty-eight days on an average.

Late Migration of Rifle Bullet from the Inferior Vena Cava to the Right Ventricle

Dr. Tuffier recently reported a typical case of tardy migration of a war projectile in the circulatory apparatus. The soldier had been wounded by a rifle bullet in the right lumbar region. The first intervention consisted of a simple dissection of the lumbar wound. A month later a roentgenogram revealed the bullet at the level of the first and second lumbar vertebrae, about 9 cm. from the anterior wall. Eight days later, a second roentgenogram showed that the bullet had disappeared from its original location and that it was then in the heart itself, moving synchronously with the pulse beats. The patient, who until then had not complained of any symptoms, said that he was suffering from oppression and distress, anginous in character. The operation was proceeded with, but had to be stopped soon after the flap had been cut in the chest wall because the patient presented symptoms of respiratory arrest, thready pulse, dilatation of the pupils and finally syncope. Under proper treatment the immediate danger was overcome, and the patient felt fairly well during the next two days, but on the third day he died suddenly.

The necropsy disclosed that the bullet had entered the body in the lumbar region, furrowed the anterior surface of the right kidney (the superior portion of this kidney had undergone atrophy, doubtless the result of the traumatic obliteration of a branch of the renal artery) and subsequently entered the vena cava, where it had burrowed in the rear outer wall of the vessel a real *logette en nid de pigeon* of the internal tunic (dry wound of the vena cava). After six weeks, the bullet left this position, reached the auricle and then dropped into the right ventricle, where it was found embedded in the myocardium.

LONDON LETTER

LONDON, March 19, 1918.

The Food Situation

Under the present system of rationing, the allowances of some of the principal articles of diet are greatly limited. But, excepting in the case of sugar, our position is much better than that of Germany, as is revealed by the following allowances of staple foods in London and Berlin:

	London	Berlin	
	Ounces	Pounds	Ounces
Butter and margarin	4		2¾
Meat	20		8¾
Sugar	8		8¾
Potatoes	Unlimited	7	10¼
Bread	Unlimited	4	4¼

Moreover, in the case of persons engaged in heavy work, it is proposed to allow extra rations, if supplies permit, as soon as possible after April 7. The supplementary ration in the first instance will be limited to bacon, rabbits, poultry, and meats other than fresh butchers' meat. At the outset the ration will be uniform for all persons classed as heavy workers. Provisionally it is expected to amount to an increase of 50 per cent. above the present ration. With a view to a possible differentiation later either in respect of the meat ration, or of other rations, the work people qualified for extra supplies will be graded in three classes: (*a*) men engaged in very heavy industrial work, and generally exposed to weather or heat; (*b*) men in agricultural work, and (*c*) men in heavy industrial work. The supplementary ration will be granted to women engaged in work corresponding to that of men in Classes A and B, but not to women doing ordinary factory work, which does not involve exceptional physical strain or exposure to heat or weather. It is expected that the total number of persons qualified to apply for the supplementary ration will be about one seventh of the population.

The Smallpox Outbreak in London

The outbreak of smallpox in the East End of London so far has not increased to any extent. The health authorities have closed the street in which the first cases occurred. They do not believe that the few cases of smallpox that have occurred need give rise to serious alarm. So far outbreaks of smallpox in London have appeared in cycles, and one of these cycles was due last year, but not a single case was then reported in the whole of London. In 1916 there was only 1 case; in 1915 there were 11, 10 of which occurred among Belgian refugees; in 1914 there was 1 case, in 1913 1, in 1912 there were 5, and in 1911 there were 70. Between 1904 and 1911 there were 60 cases; in 1904 there were 449, and between the winter of 1901 and the spring of 1902 there were 7,916.

The Treatment of Venereal Diseases

Considerable attention continues to be given to the problem of venereal diseases. At a meeting of the National Council for Combating Venereal Diseases, Sir Thomas Barlow, who presided, said that the government scheme has now been on trial for a year, and he feels sure that after another year treatment centers will have been established in nearly all towns. Lady Barett, M.D., said that experience at the venereal clinics has shown the need for further beds for infected pregnant women after repeated miscarriages and stillbirths. Gonorrhea is more difficult to cure than syphilis, especially during pregnancy, and beds are required not only for the child's sake but even more for the mother's. Dr. W. G. Savage, health officer for Somersetshire, complained that the government scheme is framed only for urban conditions. In rural districts, owing to the long distance from clinics, traveling expenses will have to be paid, but even this does not meet the loss of time. He suggested that the clinical medical officer, who should be a whole-time man, should go to the villages and make a temporary clinic of the office of the local physician, with whom he can talk cases over.

Air Raid Shelters and Infection

During the air raids, a large proportion of the population, especially women with children, take refuge in various shelters, such as underground railway stations and large buildings. Among the latter are the government schools, which are scattered all over London. The school medical officer has presented a report on the connection between crowding in air raid shelters and the increase of infectious disease. He finds that the prevalence of disease has risen in definite relation to times of crowding. The conclusion reached is that it is an open question whether recourse to shelters is not a more serious danger than the small risk that would be incurred if they were not used.

Marriages

LIEUT. WALTER LEE BRANDON, M. R. C., U. S. Army, on duty at Fort Sill, Okla., One Hundred and Fortieth Field Hospital, to Miss Lola Clark, both of Broseley, Mo., at Lawton, Okla., April 4.

MAJOR PHILIP STANLEY CHANCELLOR, M. R. C., U. S. Army, Santa Barbara, Calif., to Mrs. Charlotte Thorne Lewis, at Montecito, Calif., April 3.

LIEUT. JOHN WILLIAM MANN, M. R. C., U. S. Army, Pittsburgh, to Miss Naomi Pries of Lancaster, Pa., at Portland, Me., about March 28.

DAVID ROSWELL ROTHROCK, Milton, Pa., to Miss Zella O. Stadler of Watsontown, at Milton, Pa., March 29.

LEO RUDOLPH MOJOEWSKY, Cincinnati, to Miss Emilie Fries of Covington, Ky., March 26.

ELVIRA DUDLEY DEAN to Mr. Frank D. Abell, both of Morriston, N. J., April 2.

Deaths

Lieut.-Col. William W. Reno, Medical Corps, U. S. Army; Michigan College of Medicine and Surgery, Detroit, 1900; aged 45; a Fellow of the American Medical Association; commissioned lieutenant, Medical Corps, U. S. Army, 1901; captain in 1906; major in 1910, and lieutenant-colonel in 1917; died at sea, March 21, 1918, disappearing from U. S. S. *Susquehanna* while returning home invalided from France. Colonel Reno was conspicuous for pioneer work with the ambulance company and field hospital, the efficiency of which organizations was promoted by his initiative. His interest in the physical efficiency of the individual soldier was manifested in his study of the soldier's foot, the results of which he published. He was a frequent contributor to medical journals on varied subjects pertaining to the duties of the military medical officer. While instructor at the training camps for medical officers he endeared himself to every officer with whom he came in contact by his kindly tact and consideration.

William W. Tarvin, Covington, Ky.; Medical College of Ohio, Cincinnati, 1886; aged 53; a Fellow of the American Medical Association; formerly a member of the staff of the Speer's Memorial Hospital, Dayton, Ky., and surgeon of the Covington Protestant Children's Home; a member of the Kenton County Board of Health; for many years surgeon for the Chesapeake and Ohio Railroad in Kentucky; died, March 28, after an illness of three months from injuries received in an automobile accident.

Joseph P. Creveling, Albany, N. Y.; University of Michigan, Ann Arbor, 1870; aged 70; a Fellow of the American Medical Association; formerly served as president of the Albany Academy of Medicine, and surgeon for the Lehigh Valley Railroad; in 1905 and 1906 was president of the New York and New England Association of Railway Surgeons; died at his home, March 30, from cerebral hemorrhage.

William F. McAllister, San Francisco; University of Pennsylvania, Philadelphia, 1870; aged 72; formerly a member of the Medical Society of the State of California; assistant surgeon in the Veteran's Home of California; formerly a member of Napa County Board of Health; for fourteen years collector of the port and sometime commissioner of immigration in San Francisco; died at his home, March 26.

Harrison Girard Wagner, Cleveland; Cleveland College of Physicians and Surgeons, 1895; aged 52; a member of the Ohio State Medical Association; formerly visiting physician to the Cleveland City Hospital, and demonstrator of physical diagnosis in the Western Reserve University; also a pharmacist; died at the Lakeside Hospital, Cleveland, March 21, from cardiorenal disease.

Edward Payson Hammond Griswold, Niagara Falls, N. Y.; New York University, Medical Department, New York City, 1878; aged 62; a member of the Medical Society of the State of New York; formerly surgeon of the Forty-Second Separate Company of the New York National Guard; formerly health officer of the village of Niagara; died, April 2, at his home.

George Horsley Shedd, North Conway, N. H.; Bowdoin Medical School, Portland, 1879; aged 65; a Fellow of the American Medical Association; surgeon in chief of the Memorial Hospital of North Conway, and a member of the state board of medical examiners since 1897; died at his home, March 21, from angina pectoris.

William Parsons, Chicago; Rush Medical College, Chicago, 1874; aged 74; a Fellow of the American Medical Association; formerly chief surgeon for Armour and Company and Swift and Company, in the early days of the packing industry; formerly surgeon for the Chicago Junction Railroad; died at his home, April 6, from gangrene.

Elmer Davis Maddux, La Crosse, Ind.; Chicago College of Medicine and Surgery, 1910; aged 39; a Fellow of the American Medical Association; formerly a lieutenant in the Medical Reserve Corps; died in a hospital in Chicago, April 5, as the result of injuries received in an automobile accident.

Walter S. Daly, Ogdensburg, N. Y.; McGill University, Faculty of Medicine, Montreal, 1885; aged 59; a Fellow of the American Medical Association; a member of the American Laryngological, Rhinological and Otological Society; died at his home, March 18, from pneumonia.

William F. Patterson, Chapelhill, N. J.; Albany (N. Y.) Medical College, 1875; aged 67; formerly assemblyman for the third district of Monmouth County; collector of Middletown Township for a number of years; died at his home, March 5, from cerebral hemorrhage.

J. Albert Gaar, Jonesboro, La.; Memphis Hospital Medical College, 1904; aged 38; a member of the Louisiana State Medical Society; formerly resident physician to the New Orleans, Eye, Ear, Nose and Throat Hospital; died at his home, March 12, from heart disease.

Bartlett H. McMullen, Cadillac, Mich.; Detroit Medical College, 1879; aged 60; formerly a Fellow of the American Medical Association; a member of the Michigan State Medical Society; for two terms mayor of the city of Cadillac; died in Rochester, Minn., April 1.

Lieut. Edward Leland Mooney, Jr., M. R. C., U. S. Army, Syracuse, N. Y.; Syracuse University, College of Medicine, 1917; aged 26; a Fellow of the American Medical Association; on duty with the American expeditionary forces in France; was killed in action, March 26.

Frank Hart White, Hackensack, N. J.; University Medical College, New York City, 1883; aged 55; formerly a Fellow of the American Medical Association; a member of the Medical Society of New Jersey; died in the Hackensack Hospital, April 2, from pneumonia.

William Harold Wetmore, Oswego, N. Y.; University of Michigan, Homeopathic Medical School, Ann Arbor, 1908; aged 33; a Fellow of the American Medical Association; died at the home of his mother, Syracuse, N. Y., March 28, from tuberculosis.

Homer S. Jeffrey, Upland, Ind.; Kentucky School of Medicine, Louisville, 1894; aged 45; formerly a member of the Indiana State Medical Association; died at the Grant County Hospital, Marion, Ind., February 14, from bronchial pneumonia.

Marion Howard Cazier, Detroit; Rush Medical College, Chicago, 1880; aged 60; formerly a Fellow of the American Medical Association; died, March 5, from the effects of a gunshot wound of the head, self-inflicted, it is believed.

Clarence A. Chaloner, Stephentown, N. Y.; Albany (N. Y.) Medical College, 1881; aged 60; a member of the Medical Society of the State of New York; supervisor of the town of Stephentown; died suddenly at his home, March 20.

Elisha J. Thurman, St. Louis; Washington University Medical School, St. Louis, 1873; aged 77; a member of the Missouri State Medical Association; a veteran of the Civil War; died at his home, March 31, from senile debility.

George Scribner Ten Eyck, Syracuse, N. Y.; Syracuse University, College of Medicine, 1908; aged 37; died in New York, March 29, following an operation for appendicitis.

Robert Murdock, Wilkes-Barre, Pa.; Hahnemann Medical College and Hospital, Philadelphia, 1872; aged 70; died suddenly at his home, March 22, from heart disease.

Alanson Tucker Schuman, Gardiner, Me.; New York Homeopathic Medical College and Hospital, 1872; aged 71; died in St. Petersburg, Fla., about March 24.

Alvin Shattuck, Los Angeles; College of Physicians and Surgeons, Los Angeles, 1913; aged 37; died at his home, January 22, from pulmonary tuberculosis.

Henry Allen Wilson, Niagara Falls, N. Y.; University of Buffalo, 1882; aged 66; died at the Memorial Hospital, February 24, from Bright's disease.

William Houston Taylor, Little Rock, Ark.; Vanderbilt University, Medical Department, Nashville, Tenn., 1875; aged 70; died at his home, March 30.

Fannie W. Sanborn, Scranton, Pa. (licensed, Pennsylvania, 1877); aged 79; died at the home of her niece in Clark Summit, March 22.

Justus R. Conklin, Omaha; Rush Medical College, Chicago, 1859; aged 85; died at Dunedin, Fla., March 20, from cerebral hemorrhage.

Ozias Paquin, St. Louis; St. Louis College of Physicians and Surgeons, 1888; aged 53; died at the City Hospital, March 29.

Samuel Taylor Murray, Greentown, Ind. (license, Indiana, 1897); aged 77; died at his home, March 24, from heart disease.

A. Milliken, Placerville, Calif. (license, California, 1876); aged 84; died at his home, January 26, from bronchial pneumonia.

Maze A. L. Enochs, Flatcreek, Tenn.; University of Nashville, Tenn., 1872; aged 74; died at his home, March 17.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION

MISBRANDED NOSTRUMS

Some "Patent Medicines" for Which Fraudulent Claims Have Been Made

Ascatco.—Four dozen small and one and one-half dozen large bottles of "Ascatco" put out by the Ascatco Laboratory, New York, were seized by the government on the charge that the stuff was misbranded. The product contained 13 per cent. alcohol and some opium. It was sold under the claims, either direct or inferential, that it would cure asthma, hay-fever and catarrh, would relieve coughs and colds and would prevent hay-fever. The government charged that the claims made for the preparation were false, misleading and fraudulent. No one appeared to claim the property and the court entered judgment of condemnation and forfeiture and ordered that the article should be destroyed by the United States marshal—[*Notice of Judgment No. 4600.*]

Mexican Oil.—"Mexican Oil," manufactured by the Hausman Drug Co., Trinidad, Colo., was sold under claims that it was an effective remedy for diarrhea, dysentery, summer complaint, cholera morbus, sciatica, rheumatism, gout, bronchitis, dyspepsia and various other conditions. It was analyzed by the federal chemists who reported that it contained over 57 per cent. alcohol together with essential oils, glycerin, red pepper, emodin, menthol and a small amount of opium alkaloids. The claims made for the preparation were declared false and fraudulent. The company pleaded guilty and was fined $25 and costs.—[*Notice of Judgment No. 4616.*]

Persil.—"Persil," a nostrum of the "booze" type, was labeled as being prepared for Thompson & Co. of Boston by Arrow Distilleries Co., Peoria, Ill. It contained 40 per cent. alcohol and was claimed to contain, in addition, asparagus, parsley, celery, buchu and juniper berries. The government chemists analyzed it and declared that while it had the amount of alcohol claimed, it did not contain appreciable quantities of celery, buchu, juniper, asparagus or parsley. The government charged that the product was misbranded because it was false and fraudulently claimed that the stuff was an effective remedy for bladder and kidney trouble when in fact it was not, "but did contain ingredients which might render the article harmful when used in the treatment of diseases of the kidneys or bladder due to, or accompanied by, inflammation." The Peoria concern admitted its guilt and was fined $100 and costs.—[*Notice of Judgment No. 4635.*]

Dr. D. Kennedy's Favorite Remedy.—The Dr. David Kennedy Co. of Rondout, N. Y., shipped this product. It was found by the federal chemists to contain 18 per cent. alcohol, nearly 50 per cent. of sugar, over 4 per cent. of potassium acetate with methyl salicylate, aloes, licorice and oil of sassafras present. False and fraudulent claims were made for this stuff to the effect that it would correct the worst cases of constipation, that it was a valuable remedy for the diseases and weaknesses peculiar to females, that it was a remedy for skin diseases, rheumatism, ulceration of the kidneys and bladder, diabetes, syphilis, malaria, milk leg and various other conditions. The company pleaded guilty and was fined $50.—[*Notice of Judgment No. 4673.*]

Our Standard Remedy.—S. Donovan Swan, who did business under the name "Standard Medical Society" from Baltimore, Md., shipped a quantity of "Our Standard Remedy" to New York. The nostrum was in the form of tablets which, according to the government chemists, contained rhubarb, senna, scoparius, licorice, red pepper and some ammonia compound with indications of aloes. The label conveyed the impression that these tablets were an effective remedy for rheumatism, kidney disorders, neuralgia, dyspepsia, chills and fever, female disease, erysipelas, etc., claims that the government declared recklessly and wantonly false and fraudulent. Swan would neither affirm nor deny his guilt. He was fined $15.—[*Notice of Judgment No. 4676.*]

Dr. King's Throat and Lung Balsam.—This preparation, alleged to have been prepared by the King Medicine Co., Chicago, Ill., was shipped by the Ritchey Portrait Co. of Chicago to Georgia in violation of the Food and Drugs Act. The stuff was declared misbranded because the claims that it would relieve any ordinary cough or cold as well as any consumptive patient in the last stages of the disease were false and fraudulent. No claimant appeared for the property and the court ordered that it should be destroyed.—[*Notice of Judgment No. 4713.*]

"White Pine Expectorant" and "White Pine Balsam."—These preparations were shipped by the Allan-Pfeiffer Chemical Co., St. Louis, Mo., into the State of Illinois in violation of the Food and Drugs Act. The federal chemists reported that "White Pine Expectorant" and "White Pine Balsam" were each "essentially a sirupy solution containing a small amount of alkaloid (probably morphin), chloroform, alcohol, benzoic acid, and a large amount of plant extractives unidentified." The preparations were declared misbranded because the names indicated to the purchaser that each of the articles contained, as one of its essential ingredients, extract or tar of white pine when, in fact, neither article contained these substances. They were declared further misbranded because the labels contained false and fraudulent therapeutic claims to the effect that the products were effective remedies for consumption and all inflamed conditions of the lungs. The company pleaded guilty and was fined $40 and costs.—[*Notice of Judgment No. 4913.*]

California Tuna Tonic Tablets.—These tablets were shipped in interstate commerce by the California Good Health Co. of Louisville, Ky. When analyzed by the government chemists they were found to be coated pills containing essentially iron carbonate with a small quantity of nux vomica alkaloids (strychnin, etc.). In the circular around the bottle it was claimed that these pills were a remedy for nervous prostration, spinal affections, rheumatism, partial paralysis, insanity, consumption, leucorrhea, *la grippe* and all diseases of the nervous system. It was on a basis of these preposterous falsehoods that the government declared the pills falsely and fraudulently advertised. The company pleaded guilty and was fined $25.—[*Notice of Judgment No. 4926.*]

Alorine Antiseptic Suppository.—Henry E. Currey, who did business under the trade name Live and Let Live Drug Co. at Baker, Ore., was charged with shipping this preparation in violation of the federal Food and Drugs Act. The government chemists reported that Alorine Antiseptic Suppository was made of cacao-butter and contained quinin sulphate, boric acid and tannic acid. The circular around the bottle contained the following claims:

> "A prompt and effectual Relief for Leucorrhea, . . . Tumors, Polypus, Profuse and Difficult Menstruation, Laceration of Cervix, Gonorrhea, Falling of the Womb, and all Female complaints in General. A remedy of great medicinal value; and has been used in hundreds of the most severe cases, producing instant relief, followed by a speedy cure. . . . Important. The suppositories are a positive preventative and protection from Venereal Diseases. . . ."

The government very naturally declared that these claims were false and fraudulent and applied knowingly and in reckless and wanton disregard of their truth or falsity. Currey pleaded guilty and was fined $50.—[*Notice of Judgment No. 4929.*]

St. Joseph's Quick Relief.—The Gerstle Medicine Co., Chattanooga, Tenn., shipped this stuff in interstate commerce. "St. Joseph's Quick Relief," when analyzed by the federal chemists, was found to contain 32 per cent. alcohol with Peru balsam, camphor and red pepper. The claim was made in the trade package that the preparation was an effective and quick remedy for colic, cholera morbus, dysentery, diarrhea, neuralgia, headache, toothache, earache and various other aches. These claims the government declared recklessly false and fraudulent. The company "entered its submission to the information" and was fined $37.50 and costs.—[*Notice of Judgment No. 4939.*]

"Andrews' Wine of Life Root or Female Regulator" and "Andrews' Wine of Life Root Annex Powders."—These imposingly named products were shipped by Ernest L. Andrews, who traded as the Andrews Manufacturing Co., Bristol, Tenn. The "Female Regulator," according to the federal chemists' analysis, contained over 14 per cent. alcohol, considerable sugar and small amounts of methyl salicylate and tannin. The "Annex Powders" were composed of almost equal parts of common salt and baking soda with a small amount of washing soda. The "Female Regulator" was represented as a remedy for all diseases peculiar to the female sex, as a regulator of all derangements of the menstrual organs, as a panacea for woman's ills, as a remedy for sterility and, in fact, as a cure for all diseases from which women suffer, provided it was used in connection with the "Annex Powders." These claims were declared false and fraudulent. Andrews "entered his submission to the information" and was fined $50 and costs.—[*Notice of Judgment No. 4943.*]

Clark Stanley's Snake Oil Liniment.—Clark Stanley of Providence, R. I., sold this stuff. It was found by the federal chemists to be nothing more marvelous than a light mineral oil mixed with about 1 per cent. of fatty oil (probably beef fat), red pepper and possibly a trace of camphor and turpentine. It was falsely and fraudulently represented as a remedy for rheumatism, neuralgia, sciatica, sore throat and bunions, and as a cure for partial paralysis and effective to kill the poison from bites of animals, insects or reptiles. Stanley entered a plea of *nolo contendere* and was fined $20. —[*Notice of Judgment No. 4944.*]

Correspondence

BRITISH CORDIALITY TOWARD M. R. C. OFFICER

To the Editor:—I came over here, sailing about the 20th of July and reaching "Old Blighty" on the ———. We had a foretaste of what was coming in the following incidents. We suddenly awoke one Sunday morning to the thunder of gunfire. About 600 miles off the ——— a submarine came up about ——— behind us and commenced to shell us. Soon we were replying and putting on full steam. Ultimate score was one run for us with no hits on either side. Next day a deckhand reproved the chief gunner for his inaccuracy. He replied somewhat as follows: "You do not understand the science of gunnery, fellow. If our 6-inch shell had hit them square it would have simply put two clean holes in her sides like a punch and they could stuff them up with their coats and go on about their business. We were trying to ricochet a shot into her, by hitting the water first to slow its speed. Then the shell would have had a chance to explode inside of her and blow her up." Quite ingenious as an explanation!

On arriving at a town 24 miles behind the line, we received our first introduction to shell fire. "Good Heavens," I thought, "if this is what happens at this distance, what is the front like?" Three British colonial officers coming along just then and probably seeing the dismay on my face, laughingly dragged me into an officers' club and started a childish game of floor-croquet to make me forget it. They soon succeeded and when the bombardment was finished, went out about their business again.

Since that day the British have given me the most varied experience: four weeks in a base hospital; two weeks in a casualty clearing station; three months in the various phases of the field ambulance, at a rest station, main dressing station, advanced dressing station and as bearer officer; nearly two months as regimental medical officer and, up to the present, over two months as medical officer to a large artillery school. This position has given me an insight into sanitary problems that probably I should not have otherwise obtained.

And all the way through my associations have been with men of the most splendid type. I came over with some compunction, fearing that as a stranger, I should have a cold and unfriendly time of it. For the first two or three days this impression is confirmed. But it is only temporary. These men are coolly taking your measure or, perhaps, it is shyness. But suddenly the ice breaks and you are one of them.

I wish you could collect further expressions of appreciation for what the British are doing for us of the medical reserve and publish it. I am sure you would find everywhere the same feeling that I possess. Every one whom I have thus far met has been loud in his praise of the kindly hospitality and the keen eagerness to teach us all they possibly can, that our allies have shown us.

George S. Silliman, Lieutenant, M. R. C., U. S. Army.
B. E. F., France.

RED CROSS RELIEF WORK AT GUATEMALA

To the Editor:—The American Red Cross Relief Commission, sent by the National Red Cross to Guatemala to aid the sufferers of the earthquakes that have destroyed Guatemala City, consisting of Dr. Alvin M. Struse of the Rockefeller Foundation as medical director, Mr. J. J. O'Connor of the Red Cross as relief administrator, Mr. Edward Stuart, who recently was in charge of sanitary work for the Red Cross in Serbia, as sanitary engineer, and Mr. Mayo Tolman of West Virginia as assistant sanitary engineer have organized a large camp for the homeless on the outskirts of the city.

The United States War Department has contributed 4,000 tents for this purpose, and the American Red Cross has sent supplies and medical equipment to the value of $150,000.

Large quantities of smallpox vaccine and typhoid and paratyphoid vaccine have been sent, and the entire population of the city is being vaccinated. Preventive measures are also being taken against typhus fever and intestinal infections. A temporary water supply to replace the former system, now ruined, is about to be constructed, and the American Red Cross is shipping two chlorination plants for the disinfection of the water.

J. S. Hoagsdon, Guatemala.
Director-General, American Red Cross, Guatemala Relief.

MORE CONTRACT SURGEONS

To the Editor.—A new call for medical men for the Army has gone forth. There are many physicians who are over the age limit and yet who are able to do much work; there are others who have some slight physical defect, others who are financially unable to enlist, and finally a large class of medical teachers, who are practically the cream of the profession, and yet who are urgently needed for the training of medical students. Near many of the cantonments and camps are great medical centers or large cities, and from these a large number of physicians could be recruited for half-time medical work; they could supervise much of the work in the Army camps just as they do in civilian hospitals. Therefore would it not be wise to appoint some of these men, including specialists, as contract surgeons to give a certain proportion of their time to the Army, and to set free for more strictly military work a large number of Army doctors?

H. H. Hazen, M.D., Washington, D. C.

Syphilis and Infant Mortality.—Official statistics of public charity give a total of 458 children dead in 996 births from syphilitic women who came to be confined in the hospitals of Paris from 1880 to 1885. Proportion of infantile mortality, 46 per cent.—Alfred Fournier, *Social Danger of Syphilis*, p. 22.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

ARKANSAS: Little Rock, May 14-15. Sec., Regular Board, Dr. T. J. Stout, Brinkley; Sec., Homeopathic Board, Dr. W. B. Hughes, 900 Scott St., Little Rock; Sec., Eclectic Board, Dr. C. E. Laws, Ft. Smith.

GEORGIA: Atlanta and Augusta, May 30-June 1. Sec., Dr. C. T. Nolan, Marietta.

HAWAII: Honolulu, May 6. Sec., Dr. G. A. Batten, Box 375, Honolulu.

KENTUCKY: Louisville, May 28-30. Sec., Dr. J. N. McCormack, Bowling Green.

LOUISIANA: New Orleans, June 6-8. Sec., Dr. E. W. Mahler, 730 Audubon Bldg., New Orleans.

MASSACHUSETTS: Boston, May 14-16. Sec., Dr. Walter P. Bowers, Room 501, No. 1 Beacon St., Boston.

NEVADA: Carson City, May 6. Sec., Dr. S. L. Lee, Carson City.

NEW YORK: Albany, Buffalo and Syracuse. May 21-24. Sec., Dr. W. J. Denno, Education Bldg., Albany.

Colorado January Examination

Dr. David A. Strickler, secretary of the Colorado State Board of Medical Examiners, reports the written examination held at Denver, Jan. 8, 1918. The examination covered 8 subjects and included 80 questions. An average of 75 per cent. was required to pass. Of the 9 candidates examined, 6, including 4 osteopaths, passed, and 3, including 1 osteopath, failed, Twelve candidates were licensed through reciprocity. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
College of Medical Evangelists	(1915)	78.2
Ohio State University College of Medicine	(1917)	89.2

FAILED

College	Year Grad.	Per Cent.
University of Alabama	(1900)	*
Kansas City College of Medicine and Surgery	(1917)	71.1

LICENSED THROUGH RECIPROCITY

College	Year Grad.	Reciprocity with
Columbian University	(1899)	Illinois

Book Notices

A Clinical Manual of Mental Diseases. By Francis X. Dercum, A.M., M.D., Ph.D., Professor of Nervous and Mental Diseases, Jefferson Medical College, Philadelphia. Second edition. Cloth. Price, $3.50 net. Pp. 497. Philadelphia: W. B. Saunders Company, 1917.

This edition does not materially differ from the first, although it has been revised and to some extent enlarged and altered. It remains a good descriptive textbook. The author's strong points are delineation of clinical types and therapeutic procedures. His weak points are psychology (normal and abnormal) and, consequently, classification. The book aims to be a practical guide for students and practitioners, and it is; but with a somewhat loose or superficial psychology, and a classification here and there a bit careless, it is a guide that might occasionally lead one astray. To write about the insanity of the special fears, the insanity of indecision, and the insanity of deficient inhibition might easily mislead the inexperienced, even though the description of the patients is good, for these are not insanities at all. On page 195 the author makes the common though radical error of confusing phobia with impulse. In the chapter on psychologic interpretation of the symptoms he gives an outline of the principles and technic of freudian psychanalysis which is as fair as could be expected from an avowed opponent. It cannot be assumed to be such as would satisfy freudians. Obviously, the chapter on treatment is the result of experience and not of theory; consequently, it is good. Such details as methods of feeding and alternation of nurses will be of immediate and practical value to the practitioner. In conclusion, the reviewer is impelled to remark that to criticize a textbook on psychiatry is superlatively easy; to write a good one, exceedingly difficult.

War Nursing. A Text-Book for the Auxiliary Nurse. By Minnie Goodnow, R. N., War Nurse in France. Cloth. Price, $1.50 net. Pp. 172, with 120 illustrations. Philadelphia: W. B. Saunders Company, 1917.

This book is intended to supply the demand for a work on nursing as applied to war. While nursing and the fundamental principles governing the work are the same in civil as well as in base hospitals at the front in a war, at the same time there is a decided variance not only in the radically different conditions in surroundings, but also in that all the patients are soldiers. This fact is emphasized in the first sentence of the book: the relationship between the sick man and his nurse is one that does not exist in ordinary life. Of course there is a difference in the hospital itself, and this difference is described. The nurse, like every one else, is subject to military rules and regulations, and she must accept conditions in this regard that she might not be willing to accept in private life. She must obey without protest or attempt at evasion. "She must be a good soldier, uncomplaining, unquestionably obedient." But she has her satisfaction in that "patients are subject to the orders of the nurse, acting under the medical officers or charge nurse." While intended specifically for war nursing, this book contains information and suggestions that will be found of very practical value to all nurses, for, as we have stated, nursing is the same to a great extent no matter whether in a war or in a civil hospital. The book is full of good, common sense, of practical instruction and of sound advice. It is also well illustrated.

Oral Roentgenology. A Roentgen Study of the Anatomy and Pathology of the Oral Cavity. By Kurt H. Thoma, D.M.D., Lecturer on Oral Histology and Pathology, Harvard University Dental School. Cloth. Price, $4 net. Pp. 213, with 311 illustrations. Boston: Ritter & Co., 1917.

This book is a roentgenographic atlas consisting of 311 halftone reproductions of roentgenograms of the teeth and maxillary bones, and thirty-five pages of text. It is divided into four parts: (1) studies of the normal tissues; (2) studies of pathologic oral conditions; (3) use of roentgenograms as an aid in treatment, and (4) examination of the oral tissues in somatic disease. The first part illustrates the development of both the temporary and the permanent teeth, and the structure of the several regions of the maxillae and mandible. In the second part there are forty-three illustrations of unerupted and misplaced teeth, mostly lower third molars and upper cuspids; forty-one in the group illustrating alveolar abscess, twenty-seven in the group illustrating chronic pericementitis, three of fractures of the mandible, two of odontoma, and eleven of various types of cysts. The third part is devoted almost entirely to root canal fillings, and a number of groups showing alveolar abscesses, the condition immediately after amputation of root apexes, and at subsequent examinations. Brief case histories accompany many of the illustrations and add to their interest. Most of the illustrations appear to be unusually good reproductions of the roentgenograms. The book would be of greater value if both the text and the case histories were extended. Four new terms are used: radiability, the property of an object to transmit the ray; radioparent, offering no barrier to the ray; radiolucent, offering slight resistance, and radiopaque, impervious to the ray.

Soins oculaires à l'usage des infirmières. Par H. Coppez, Agrégé à l'Université libre de Bruxelles, et A. Van Lint, Chef de Service à la Policlinique de Bruxelles. Paper. Pp. 186, with 114 illustrations. Paris: Masson & Cie, 1916.

This small French volume, which might be compared to the various compends published in the English language, is profusely illustrated, many of the illustrations admirably portraying the subject matter. The book is divided into four parts. The first part describes the anatomy and methods of examination of the eye. The second part is devoted to therapeutics in general, explaining the use of bandages, thermotherapy, electrotherapy, massage, cupping, etc. The third part deals with surgical technic, preparation of the patient, the operating room, care of instruments, and postoperative treatment. The fourth part contains brief descriptions of special conditions, tells how to handle children and emergency cases, gives directions for instructing the patient how to insert and remove an artificial eye, and finally enumerates a list of the medicines and instruments most commonly used. The book is a multum in parvo, and will serve as a handy reference book to oculists engaged in dispensary practice.

Medicolegal

Liability for Cataract Where No Operation Is Had

(Joliet Motor Co. vs. Industrial Board et al. (Ill.), 117 N. E. R. 423)

The Supreme Court of Illinois reverses a judgment that confirmed an order of the industrial board sustaining an award to one Goodwin of $9 per week for 100 weeks for complete loss of sight of his left eye, to be paid by the Joliet Motor Company, the board taking the position that it had no power to force an operation for the removal of a cataract. The court says that Goodwin, while in the employ of the motor company, was injured, May 2, 1914, by a particle of steel entering his left eye; that a cataract gradually formed on the eye; and that Aug. 18, 1915, fifteen months after the accident, was fixed as the time when there was an entire loss of sight. The evidence was that an operation for the removal of a cataract is neither serious nor dangerous to an ordinary person in good health, and a very large majority of such operations are successful. There was a good probability of recovering normal vision for ordinary purposes by removal of the cataract, and the industrial board found that Goodwin ought to have the operation performed. The fact that the board had no power to force him to submit to an operation did not determine the question involved, which was whether the total loss of sight was attributable to the accident, which caused the slow growth of a cataract, or to an unreasonable refusal of Goodwin to have the cataract, which caused the loss of vision, removed. The statutory provision for reducing or suspending compensation if an employee shall persist in insanitary or injurious practices, which tend either to imperil or to retard his recovery, or shall refuse to submit to such medical or surgical treatment as shall be reasonably essential to his recovery, does not apply to an original application for compensation on account of an entire loss of the sight of an eye when the question to be decided is whether that loss is due to an unreasonable refusal to remove the cause. The evidence was that the proposed operation would not be attended with any risk, and appeared to be such as any reasonable man would take advantage of, if he had no one against whom he could claim compensation, and the board found that it was the duty of Goodwin to have the operation performed. Under that finding the refusal of Goodwin was unreasonable, and the continued loss of sight should be attributed to such refusal, and not to the accident. The order of the board was not consistent with its finding. If the operation for the loss of sight should be had, and prove unsuccessful, the Joilet Motor Company would be liable for the loss of sight, as well as the surgical and hospital services necessary for the operation and the treatment already received; but, if successful, its liability would be for the temporary loss of time and treatments had, and surgical and hospital expenses necessary for the operation, and if the operation should not be a substantial success there would be a different basis of compensation from a case of total loss of eyesight. It was urged that no claim for compensation was made on the Joliet Motor Company until after the expiration of more than six months after the accident; but the foreman knew of the accident when it occurred, and afterward the company's manager offered Goodwin $200 in settlement of the injury. Goodwin told the secretary or treasurer that he was going to look to the company to reimburse him, and the manager said that was all right, and advised him to take care of the eye. The notice was sufficient.

Wife's Separate Estate Obligated to Pay for Medical Services

(Charron v. Day (Mass.), 117 N. E. R. 347)

The Supreme Judicial Court of Massachusetts overrules exceptions to a finding for the plaintiff in this action by a physician against an executor to recover for services rendered to the defendant's testatrix during a period of years prior to her decease. The court says that the testatrix was then a married woman living with her husband, who worked for the support of the family and furnished her the money with which she paid the household bills, including certain cash payments to the plaintiff.

The law implies an obligation on the part of the husband to pay for medical attendance rendered to his wife. But under present statutes the wife also may incur an obligation to pay for such attendance. Massachusetts Statutes of 1910, Chapter 576, whereby a married woman may be held liable under stated conditions jointly with her husband for debts for necessaries not exceeding $100 in value, have no application to the facts of the case at bar. But a married woman may bind her separate estate to pay for necessaries furnished to her by an express promise or by conduct and words from which an intentional obligation to that effect may be inferred. The auditor's findings bearing on this point were that:

> "No express agreement was made by Mrs. Day to pay Dr. Charron for his services. . . . Mrs. Day often told Dr. Charron that there would be property enough left by her after her death to pay him and that he would get his pay. . . . All payments made on account of this bill were cash with the exception of one item of credit, which was one load of hay, Dec. 5, 1910, $10. Mrs. Day owned the land from which this hay was cut and knew of the transaction. . . . His charges were made against Mrs. ——— Day and whenever payments were made on account of his bill Mrs. Day made them or they were made by her direction," presumably, however, out of money furnished by her husband. "I do not find that . . . she knew the amount of Dr. Charron's charges against her, nor that she knew that Dr. Charron was charging her for services to other members of the family, nor do I find that there was ever any promise to pay on her part any bill of Dr. Charron during her lifetime, but that she told the doctor that, if you do not get your money now, 'you will some time after my death. . . ."

The finding was against the plaintiff so far as services rendered to other members of the family were concerned, and no question arose on that point.

The request of the defendant for a ruling that the plaintiff could not recover was denied rightly in view of these findings of fact. The testatrix knew the attendance was rendered to her and apparently knew that the charges were made against her. One credit on the account was made seemingly out of her property with her knowledge and consent. The finding that there was no "express agreement" on her part to pay must be considered in connection with the further finding that she said to the doctor that she would leave property enough to pay the bill, and that he would get his pay after her death. The fair implication of these words might reasonably be found to be that she intended him to understand that her estate should be bound to pay his charges, if they were not paid before her decease. If this was so, then it would be equivalent to a direct promise to pay the debt after her death. A contract to pay money after one's own death is valid.

Cross-Examination Allowed as to Previous Ailments

(Lampel v. Goldstein et al. (N. Y.), 167 N. Y. Supp. 576)

The Supreme Court of New York, Appellate Term, First Department, says that, in this action to recover damages for personal injuries, the plaintiff's physician testified that he treated her for about two weeks after the accident for contusions and lacerations, and for a hysterical and nervous condition. He further testified, on cross-examination, that he had treated her professionally before the accident and also treated her after the expiration of the two weeks. The trial court, however, refused to allow the defendants to question the physician about the nature and symptoms of the ailments for which he treated the plaintiff shortly before the accident and shortly after the two weeks following the accident, apparently basing its ruling on the question of privilege. This was clearly error, as, the physician having been called as a witness by the plaintiff, the defendants had the right to cross-examine him about the other ailments from which the plaintiff had suffered before the accident, and to bring out, if possible, that the hysterical and nervous condition treated by him after the accident was due to the previous ailments.

13 *The Eye in Dementia Praecox. F. F. Teal, Lincoln, Neb.—p. 185.
14 Artificial Daylight Illumination for Perimetric Study and General Office Use. L. C. Peter, Philadelphia.—p. 189.

13. **Eye in Dementia Praecox.**—Teal's observations include an examination of fifty-three cases of *dementia praecox* and thirteen cases of manic-depressive insanity. The most constant feature of the change in retinal appearance was the dilated and sometimes tortuous condition of the veins, together with the contracted arteries. The disk at times was of a normal appearance, while at others it would range from a hyperemic condition to a quite well marked papillitis, and occasionally the inner side was congested, and the temporal side pale. The cupping was normal in 40 per cent., diminished in 45 per cent. and filled in 15 per cent. The fields were examined in 15 selected cases of dementia praecox in the more recent stages of the disease. The charts showed in the majority of instances the concentrically contracted field for form and color, with frequent interlacing of the color fields. The contraction ranges from slightly less than normal to 30 degrees, which is practically the same result shown in the investigation of the others mentioned. The manic depressives showed the cup filled with deep congestion, in 35 per cent. and partially filled in the remainder, even to slight elevation.

56 Ionization of Proteins and Antagonistic Salt Action. J. Loeb, New York.—p. 531.
57 Study of Nonprotein Nitrogen of Wheat Flour. *M. J. Blish,* Bozeman, Mont.—p. 551.

34. **Fat and Lipoids of Dog's Blood Before and After Experimental Anemia.**—The results obtained by Dubin are *in* accord with the findings of Bloor in pernicious *anemia* associated with carcinoma of the stomach.

35. **Animal Calorimetry.**—It is clear from Atkinson's work that mechanical work has no influence on the hourly rate of absorption of protein or on the intensity of the hourly *metabolism of protein* in a dog which has been given *meat* in large quantity.

38. **Analysis of Doe's Milk.**—A 4 months old virgin *doe kid* spontaneously commenced to secrete milk having all the

characteristics, properties, and chemical composition of the milk secreted by its mother and other goats under observation. At no time, from the earliest secretion of milk to the present time, has there been any colostrum secreted. Hill thinks that this would indicate that the secretion of colostrum is associated with and possibly is produced by the cessation of pregnancy and may not occur in lactation not associated with pregnancy.

40. **Fatty Acids in Human Blood.**—Csonka states that unsaturated fatty acids are a product of normal metabolism, being present in normal human blood, in which they form 48.0 per cent. of the total fatty acids. Judged by their iodin absorption power there are, in addition to oleic acid, other unsaturated fatty acids both higher and lower than oleic, although in small amounts. The iodin numbers of the unsaturated fatty acids in pathologic conditions are generally higher than in normal individuals, especially in cases with low hemoglobin values. As such acids exist in normal human blood as well as in pathologic conditions without anemia, Csonka says, it is necessary to look further for the primary cause of toxic hemolysis.

46. **Effect of Potassium Bromate on Enzyme Action.**—The authors found that potassium bromate appears to exert consistently favorable influence on the digestion of casein by trypsin in vitro in the dilutions studied, the action being most marked at bromate concentrations of 1 part in 100,000 to 1 part in 200,000. Potassium bromate in concentrations of 1 part or more in 10,000 appears to exert a slight inhibitive influence on the digestion of casein by pancreatin, while in higher dilutions (1 part in 200,000 or 1 part in 250,000) it appears to exert a stimulating action.

48. **Studies of Experimental Scurvy.**—Pitz succeeded in producing scurvy in the guinea-pig by feeding a ration of unmilled grains and milk.

Journal of Urology, Baltimore

62 *Absorption of Drugs and Poisons from Bladder and Urethra. Absorption of Apomorphin and Morphin. D. I. Macht, Baltimore.—p. 43.

58. **Chemical Blood Observations in Urologic Cases.**—Observations are reported by Squier and Myers on seventy-five cases divided as follows: Fifty-eight cases with prostatic obstruction, seven nephrectomy cases, one double decapsulation in a case of bichlorid poisoning and nine miscellaneous urologic cases. Data have been collected on these cases for the past three years. Emphasis is placed particularly on the usefulness of the urea nitrogen estimation. Since an appreciable retention of creatinin does not occur until the impairment in renal function is advanced, it would appear to be of decidedly less value as a preoperative test than the urea, although a high creatinin, when found, would indicate the inadvisability of operating. In the prostate series, seven cases showing 3.5 mg. or more creatinin were all among the fatal ones. There were several cases in which the determination of the blood sugar data was of special diagnostic significance (diabetes). Excepting these cases, a few others showed blood sugars appreciably above normal (those above 0.16 per cent.), in which glycosuria was not noted. Some of these are associated with the retention phenomenon of advanced nephritis, but a few would appear to be mild cases of diabetes in which the condition had not been disclosed by the urine examination. The authors state that cases showing urea nitrogen figures under 20 mg. per 100 c.c. of blood may be regarded as good operative risks so far as the kidneys are concerned. When the urea nitrogen figures are found between 20 and 30 mg., and especially between 25 and 30, the patient should be operated on with considerable caution and best after a period of preliminary treatment directed to relieve the nitrogen retention. The gas-oxygen method is the anesthesia of choice. The data recorded indicate that with urea nitrogen figures over 30 the operative prognosis is bad.

60. **High Frequency Current.**—Young says that the employment of the high frequency current in cases of calculus, incarcerated in the intramural and intravesical portions of the ureter, is successful in enlarging the orifice sufficient to permit its passage. Furthermore this operation is simple, can be carried out without anesthesia, and does not produce more than slight hemorrhage.

62. **Absorption of Apomorphin and Morphin.**—Macht found that the absorptive power of the posterior urethra is distinctly greater than that of the anterior.

76 Lessons Derived from Training of Medical Officers. B. F. Duckwall.—p. 326.

70. **Injuries of the Head.**—The rules for operating which Gage has laid down for himself are as follows: In all cases of localized pressure, as determined by localized symptoms of paralysis or cortical irritation, operate. In every suspicious border line case, determine condition of bone over suspected area by exploratory incision of scalp. In every depressed fracture simple or compound, with or without symptoms, elevate. In all depressed or perforating wounds remove all sharp spicules of bone that can be felt loose or detached in the wound; leave the edges of the bony opening and the under surface of the skull around it clean and smooth. Remove foreign bodies always if they are likely to cause infection, or if they are giving rise to symptoms—in other cases, for instance, in case of small bullets, remove when possible without too much traumatism to the brain, remembering always that the possibility of such becoming harmlessly encysted, is better than the certainty of destroying important cerebral centers.

England, France and Germany agree that operation should be done as soon as possible after the receipt of injury, but they are equally insistent on getting the wounded back at least to the evacuation hospital if it can be done. After operation they should not be moved again until convalescent, so that if they are primarily evacuated to a field ambulance or field hospital nothing should be attempted there except the shaving, scrubbing, trimming and dressing. They should then be immediately evacuated to a more quiet and permanent hospital where operation should be done at once if indicated. How extensive should the first operation be? Here the English and German are inclined to be rather conservative, while the French are much more radical—all agree that the first thing to be done is to trim off any crushed and infected tissue, so that the danger of sepsis, which is rendered much greater than in civil life by the nature of the wounds and the delay in transportation, may be minimized. If received at an evacuation hospital the French advocate doing all that is necessary at once—even to removal of foreign bodies. This latter is accomplished after careful roentgen ray localization by the use of the little finger and a gallstone scoop, the wound is closed without extradural drainage and dural defects closed by pieces of fascia or with rubber tissue. Gage prefers the latter.

The English and Germans lay the same stress on thorough removal of devitalized and infected tissue and on closure of wound with only extradural drainage, but are much less inclined to remove deep seated foreign bodies unless indications, that is, symptoms, are very clear. Sergeant and Holmes found the late results of those wounded, evacuated to hospitals, in England so good that they recommended only such surgical interference at the front as may be called for to establish necessary drainage and the healing of the wound. An interesting work, in the way of reconstruction, has been done by the French in filling up defects in the skull with pieces of cartilage taken from the cartilages of the ribs; a shaving $\frac{1}{16}$ to $\frac{1}{8}$ inch thick taken from the rib cartilage, its full width and length if possible, is placed in the defect.

71. **Treatment of Light Casualties in Military Hospitals.**—The purpose of Lee's communication is to try to point out the advantages of a first class department devoted to the diagnosis and treatment of these so-called light cases. A proper solution would be to have what is known as an outpatient department, especially designed and adequately officered for the treatment of these cases. In contrast to civilian hospitals, one frequently sees, in the same wards, patients who are critically ill or seriously wounded and those who have little the matter with them, and who in civil life would be treated in an outpatient or dispensary department. It would seem wise to recognize this fact as has been done in many of the large civil hospitals, and to have a somewhat distinct, but at the same time closely related, outpatient or dispensary department for ambulatory patients. By this distinction it would be possible to concentrate special ward attention on the very sick and on the seriously wounded, and likewise, by the furnishing of adequate facilities, to care effectively for ambulatory patients, who are of so great value from a military and economic viewpoint. The ambulatory patients could be adequately housed in barracks with a minimum requirement for nurses and orderlies. This would mean the establishment of an outpatient or dispensary department in connection with every hospital.

The outpatient department should be commodious, built of wood, with adequate light and heat if necessary. It should have adequate facilities for the dressing of all wounds. There should be a room for minor operations, such as the opening of boils, small abscesses, and the removal of subcutaneous foreign bodies. This, in itself, would prevent the overcrowding of the main operating room, which is now inevitable in times of pressure. There should be opportunity for complete physical examinations. The various specialists should have compartments or rooms for their use. Experience has indicated that the usual roentgen ray equipment in the base hospital is hardly adequate to take care of both the severe cases and the light cases. Yet, in connection with the light cases, the determination of the presence or absence of a fracture or foreign body is often the deciding point as to the disposal of the case. It would be well to consider the establishment of a roentgen-ray plant, of relatively small capacity, in direct connection with the outpatient department. This would add greatly to the efficiency of the organization.

72. **Uncinaria in Army.**—Of 6,159 examinations of feces for uncinaria eggs made by the authors, 1,504, or 24.4 per cent., were found positive. The work was accomplished in less than a month by a detail of fifteen enlisted men with the cooperation of regimental surgeons in the collecting of specimens and the administration of treatment. Oil of chenopodium was used in approximately 5,000 doses without untoward manifestations. Reexamination of all the positive cases, three weeks after treatment, is now in progress and indicates that good results are to be looked for. A second treatment has been given in a few cases and a third and fourth is contemplated, until all cases are cleared up as nearly as possible. The outcome of such a survey should result in a more efficient fighting force, a diminished susceptibility to contagious disease among the men and an increase in resistance, should infection be contracted.

75. **Reaction Following Use of Antipneumococcic Serum.**—Only twice in a series of 200 cases did the authors see symptoms during the giving of the desensitizing doses. One patient had a slight nausea lasting for ten minutes after the 4 c.c. dose. The other patient had an urticaria over a small area surrounding the site of the 2 c.c. dose. In both cases the reaction following the therapeutic dose was very mild. For treatment 100 c.c. of serum is the dose usually used. This is diluted with 100 to 150 c.c. of normal salt solution, heated to slightly more than body temperature and injected slowly into the vein, the conducting tubes being warmed with hot-water bottles. It is the endeavor to inject the serum so slowly that half an hour will be consumed in the process. The reaction that follows is never the same in any two patients, neither is it the same in the patient when the serum is exhibited more than once. A patient having a severe reaction the first time may escape the reaction altogether on repeated doses, or may have a mild reaction or, again, one as severe as in the first instance. Some cases that have little or no reaction on the first dose will show most profound symptoms on the second. The interval of time between doses seems to have no bearing on the reaction with the second dose, although the longest period that has elapsed between doses is ninety-six hours.

The reactions following the use of antipneumococcus serum are so various that one can never be sure just what to expect. The reaction may begin as early as ten minutes after the serum of the final dose begins to enter the vein, or it may be delayed for some time after the treatment is over. The typical reaction may be divided into four stages occurring in rapid succession and a series of secondary symptoms occurring some days later. The first stage may be termed the stage of irritability, the second the stage of shock, the third the stage of hyperpyrexia and the fourth the stage of relaxation. Any of these stages may be very lightly stressed or even absent entirely. If any of the syndrome be absent it is more apt to be the symptoms of shock. The third stage is not always well marked, although some hyperpyrexia is practically always present. Because the reaction starts mildly or severely it does not follow that the subsequent stages are going to develop as initiated.

101. **Cancer of Stomach.**—During a period of twenty years, 651 resections of the stomach for cancer were done at the Mayo Clinic. Of 427 patients operated on more than three years ago who recovered from the operation, 311 have been traced; 120 (38.6 per cent.) were alive three years or more after operation. Of 313 patients who were operated on more than five years ago, 239 who recovered from the operation were traced, and 62 (26 per cent.) of these were alive five years or more after operation. No special effort was made to trace patients after the five-year period, but incidentally it was learned that 35 lived six years or more after operation, 27 lived seven years or more, 18 lived eight years or more, 10 lived nine years or more, 7 lived ten years or more; 5 lived eleven years or more, 3 lived twelve years or more, and 1 lived more than fifteen years after operation.

107. **Skin Infection Due to Bacillus Mucosus-Capsulatus.**—A peculiar ulcerative lesion of the skin following a suprapubic prostatectomy in a man 83 years of age, was found to yield an organism resembling the *Bacillus mucosus-capsulatus*. After running a clinical course of over three weeks with no improvement, it responded quickly to a single cauterization with stick silver nitrate.

108. **Gunshot Wounds of Cranium.**—Of forty-six patients on whom craniotomy was performed following gunshots nine died. None of the patients operated on early developed epilepsy while under observation, but bromids were given as a routine to all who could take them. The author still believes that occipital wounds offer the poorest and frontal the best prognosis on the whole. Considering the variance in mortality where foreign bodies are removed and left in the brain, he is inclined to advocate again their early removal. From the observation of these head wounds, on his own service, and of those of several other surgeons at the clearing stations, Speed believes that much dreaded hernia cerebri seldom follows early operation. Middle meningeal hemorrhage was encountered six times, with only one death, after operation and ligature. Three of these cases sustained depressed fractures of the skull. Bone sinus injuries were found five times. The frontal and mastoid sinuses were involved. When this complication is present with brain injury, it seems wiser to perform an early radical operation to avoid possible infection from the sinus lining. There was only one death in this group of patients, that was undoubtedly influenced by the presence of other wounds. When the frontal sinus connected with the wounded cortical area it was considered best to remove carefully by gentle curettage all mucous surface and to leave small drains to the depth of the sinus.

With four instances of blood sinus injury, there was but one death. These sinus injuries are extremely interesting on account of the tremendous hemorrhage which arises when depressed bone adherent to the sinus wall is removed. On the whole it appears better to leave depressed bone alone under these conditions and to prefer to take a chance on subsequent septic sinus thrombosis rather than to excite an uncontrollable hemorrhage. Gauze packings or packing with a piece of muscle belly removed under sterile precautions from another part of the patient will sometimes control the bleeding quickly. Another technical possibility lies in inserting fine stitches in the dura about the area which threatens hemorrhage. A suitable piece of fascia lata with muscle adherent on the under surface is prepared from the patient's thigh. One end of each thread of the dural stitches is then caught around the edge of the transplanted fascia and muscle at proper intervals, the depressed bone is removed, and if hemorrhage follows, the transplant is rapidly tied into place to control the leakage. The symptom of generalized muscular rigidity, so indicative of blood sinus injury, was present in two of these patients. Partial aphasias were quite common. They were for the most part motor (ataxic) and less often sensory. No instances of optic amnesic aphasia nor auditory aphasia (word-deafness) were encountered. As expressed elsewhere the author still has doubts about the validity of Broca's speech center in the left third frontal convolution. All instances of aphasia made rapid improvement while under observation, and promised ultimate recovery.

109. **Treatment of Septic Abortion.**—The treatment which Ries recommends and carries out in cases of septic abortion is as follows: If a patient with septic abortion is admitted to the hospital, expectant treatment is followed until the abortion is completed spontaneously. Rectal examination is used exclusively and that as rarely as possible. The patient is kept in bed and on a light diet. If severe or protracted slight hemorrhage makes interference unavoidable, the uterus is packed. The packing is removed after twelve to twenty-four hours and frequently the whole remnants of the abortion come away with the packing. If not, the packing has usually dilated the cervix sufficiently so that the uterus can be emptied manually. Repeated packing is not favored as dangerous in itself. If the uterus is not empty after the removal of the packing, it is emptied preferably by hand, if necessary after additional dilatation with Hegar's dilators and if the hand is insufficient, with the sharp curet. The longer the interval between the last rise of temperature and the operation the better. Packing afterward is avoided, unless necessitated by severe hemorrhage. The uterus is never irrigated. Ergot is given only when hemorrhage exists after complete evacuation of the uterus. Vaginal douches are never given until at least a week after the abortion and then only for subinvolution, not for purulent discharges. If the temperature is normal after the abortion, the patient is allowed out of bed at any time she feels ready, unless she is very anemic. The patient is fed well as soon as possible. The patient is discharged three days after the last rise of temperature, unless anemia, subinvolution, etc., require longer hospital treatment. Rectal examination is repeated before discharge.

110. **New Joint Formation in Arthroplasty.**—The changes which follow resection of the articular surfaces and construction of a new joint were carefully studied by Phemister

and Miller. Dogs were operated on by three methods: the no-flap; free flap; pedunculated flap. The results showed that it matters little in experiments on the normal knee and elbow joints of dogs, whether arthroplasty is performed by the no-flap, pedunculated flap, of free flap method. The flaps when used very largely break down and the newly formed joint is about the same, both structurally and functionally, following the three types of operations. The most important steps are the construction of a well-fitting new joint, the excision of any thickened or obstructing fibrous tissues and proper after-treatment for the maintenance of mobility.

7 *Gonorrhea Complicated by Syphilis. N. P. L. Lumb.—p. 285.

1. Postoperative Thrombosis and Embolism.—McCann believes that transfixion or ligating blood vessels *en masse* favors the development of postoperative thrombosis and embolism. Statistics favor the view that thrombosis and embolism more frequently follow operation on the female genitalia than in other situations. This preponderance was explained by the nature of the tissue involved, but McCann came to the conclusion that the operative technic must also be at fault. He therefore determined to give up transfixion and to operate anatomically, picking up vessels cleanly and ligaturing them without encompassing masses of tissue. The result has been that he has never had another case of postoperative embolism or thrombosis either in private or hospital practice. He says that "never transfix a vascular area" should become a surgical axiom. By transfixion vessels are liable to be punctured and bleed either externally or into the tissues; the transfixing ligature is tied to arrest the bleeding, and the result may be that the ligature remains in the lumen of the vessels. If this ligature is of doubtful asepticity or becomes subsequently infected, the natural process of clotting in the vessel may be arrested, the clot liquefying and becoming detached in portions or in its entirety. Although the diminution of sepsis has been a great factor in improving results, yet it is worthy of note that it is not the severe infections that are followed by these troublesome complications, but rather those of a milder type. If a vessel has been punctured the ligature should be withdrawn and the vessel clamped and tied after removal of the blood clot. The object of a ligature is to approximate the coats of a vessel and to keep them in apposition, not to cut them; hence, do not tie or stitch too tightly and cut into blood vessels.

2. Myomectomy or Hysterectomy.—Experience has convinced Bonney that the practice of myomectomy as an alternative to hysterectomy should be considerably extended. He now frequently performs the conservative operation with complete success, where a few years ago he would have removed the uterus. When the tumors are small or of moderate size, the proceeding can be carried out very well through a transverse incision across the pubic hair field. This is a great advantage in relatively young women, especially if unmarried, for it leaves no visible scar.

3. Laminectomy for Gunshot Wound.—In the three cases reported by Hughes, (*a*) the paralysis was incomplete in the sense that sphincter trouble was absent; (*b*) the injury was indirect, and due to damage to the spinal column and not to the cord itself; and (*c*) recovery was complete. The immediate effects of the operation in restoring or improving the circulation in the cord were not determined in any case. The dura was not opened in any one of the three cases.

7. Gonorrhea Complicated by Syphilis.—Lumb emphasizes the fact that modern antisyphilitic treatment at times (1) stirs a latent gonorrhea into activity; (2) leads to the development of complications; (3) renders the gonorrheal lesions very intractable. A patient presenting himself with signs of both syphilis and gonorrhea is commonly given thorough antisyphilitic treatment without delay, while the sum total of the treatment advised for gonorrhea is an irrigation twice a day with permanganate of potassium. This plan is unsatisfactory.

10. Treatment of Leprosy.—A year's further experience has confirmed Rogers' previous observation that intravenous injections of the sodium salts of the fatty acids of chaulmoogra oil obtained from the seeds of *Taraxtogenos kurzii* produce reactions in leprous tissues with breaking down of the acid-fast bacilli, which reactions are followed by great improvement. The higher melting point acids, which furnish sufficiently soluble salts (melting points of from 49 to 62 C.) are considerably more active than the lower 37 C. melting point acids first used by the author for injection. Subcutaneous injections do not produce reactions in the leprous tissues and are less effective than intravenous ones. Prolonged oral administration in quantities of 20 grains and upward daily has a good effect, especially if intravenous injections have previously been given and also in conjunction with them. Between one and two years were required to cause the lesions to disappear in the successful cases treated by Rogers, but, he thinks, that this period may possibly be reduced by the use of the more active higher melting point preparations, which have only been under trial for the last six months. The lesions have disappeared in 50 per cent. of cases treated within three years of the onset of the disease, including cases treated for only three to twelve months, but in cases of from three to fifteen years' duration, only 25 per cent. cleared up under the treatment. The most active constituent of the oil has not yet been obtained in a pure state.

During the last fourteen months Rogers has employed the intravenous route very extensively, and has now given well over 1,000 intravenous injections of the drug without any ill effects beyond temporary giddiness and headache and occasional localized clotting in the veins, while the results have been most encouraging. The sodium salts of the fatty acids obtained from chaulmoogra seeds are dissolved in water in a strength of 3 per cent., so that 2 c.c. contain 1 grain of the salts, which allows of the ready calculation of the doses in either grains or fractions of a gram. The solution may be sterilized in an autoclave and 0.5 per cent. phenol added, or it may be phenolized first and then heated on a water bath to 100 C. for twenty minutes. Rogers begins treatment with at least half a grain in 1 c.c. and increases by 0.5 to 1 c.c. at a time until 2 to 2½ grains in 4 or 5 c.c. is reached, provided severe giddiness is not produced. The higher melting point preparations are slightly more toxic than the lower ones. The injections may be given once or twice a week, and on the other days 2-grain pills or tablets of the drug may be taken by mouth after meals, beginning with one three times a day and increasing by one daily until ten or twelve are taken each day, as long as the digestion is not disturbed or giddiness produced; some patients are able to take as much as 40 grains in twenty pills daily with advantage. In most of the cases detailed only intravenous injections were given and no pills taken, so that good results can be obtained with the injections alone. This is of importance in leper asylums with strictly limited incomes.

15. **Spirochete from Case of Rat-Bite Fever.**—The rat-bite fever of the patient under consideration was caused by the inoculation of a specific spirochete by the bite of the rat which had probably a generalized spirochetosis. The spirochete recovered from the human lesion was quite different from any hitherto described, being from 2 to 3 microns in length and showing only two or sometimes three curls. This spirochete was communicable and pathogenic to mice and rats. Before the demonstration of the virus in the papules, the typical paroxysms of the fever with crises and relapses suggested a spirochetal infection clinically, and the subsequent demonstration of the spirochetes in the lesions confirmed the diagnosis. The complete cure after the injection of neosalvarsan and the rapid disappearance of the eruption (on the third day after the injection) is considered by Row to be further evidence of the spirochetal cause of the symptoms in the case under consideration.

17. **Mercuric Chlorid in Treatment of Enlarged Spleen.**—Fifty cases of chronic malaria with enlarged spleen were treated by Greig and Ritchie with mercuric chlorid and quinin and fifty-four cases with quinin alone, the latter being controls. The procedure was to administer intravenously 11 c.c. of a 1 to 1.000 mercuric chlorid solution in normal saline on alternate days; and a daily dose of 30 grains quinin in three portions was given by the mouth to both injections and controls. The injections covered a fortnight—eight doses being given—and were then stopped, but quinin was continued for another week to all the patients and a final inspection of the spleens was made at the end of the third week. Very few patients had fever and all were on splenic mixture containing 5 grains quinin per dose two days before the test began. The results of the authors' observations have brought out several points of considerable interest. In the first place, their experience does not entirely confirm the work of the American observers as regards the reduction in size of the spleen by combined treatment with intravenous injections of perchlorid of mercury and quinin, although the combined method of treatment had a greater effect in reducing splenic enlargement than quinin alone. The group on quinin alone had sixteen cases in which treatment failed, while the group on quinin and mercuric injections had only seven failures. Sixteen cases of the combined treatment series showed a two-fingers reduction in size of spleen as compared with eight in the case of quinin alone.

29. **Palmyra Fiber, Suturing Material in Place of Silkworm Gut.**—This fiber is obtained from the fibrous netting that surrounds the bases of the leaves of the toddy palmyras growing luxuriantly on the West Coast, especially Malabar. The fiber is easily obtained and can be had in all required sizes, requires very little preparation before it is ready for use and is easily preserved, keeps well and is easily sterilized, is fairly strong and sufficiently flexible, is phenomenally inexpensive and the supply is well nigh inexhaustible. The author strongly recommends the use of palmyra fiber in all cases in which silkworm gut is used.

41 Anesthetic and Other Notes. R. W. Hornabrook.—p. 143.
42 Dermatomycosis in Mice and Men. H. Lawrence.—p. 146.

38. **Ruptured Duodenal Ulcer.**—An alcoholic dyspeptic, aged 61. had sudden intense general abdominal pain with bilious vomiting. When seen thirty hours later he had an abdominal facial aspect, was perspiring profusely; pulse rate 70; temperature normal; no actual collapse. The abdomen was generally tender with increased pain over and at a level of the umbilicus; right-sided rigidity, more marked at the lower quadrant. His case was regarded as an acute appendicitis. The abdomen was opened forty-eight hours after the

onset by the usual appendix incision, and the appendix, which was in a state of chronic thickening, but quite quiescent, was removed and a quantity of thin creamy fluid with fibrinous flakes evacuated. No free gas was noticeable. A paramedian incision made in the epigastrium revealed a small ruptured ulcer in the anterior part of the first portion of the duodenum and a generalized plastic peritonitis. The duodenal area, the right kidney pouch and the pelvis (through a suprapubic stab) were all drained after closure of the ulcer. The patient progressed well for a fortnight, when he experienced a sudden attack of sharp pain in the left side of the chest. There was detected a slight pleuritic rub. The attack was succeeded by a continuous pulse rate of over 110, and for three nights there was a slight nocturnal rise of temperature to 38 C. Early the next morning he suddenly coughed up quantities of blood-stained pus, and died suffocated in six hours. Permission to perform a postmortem examination was not obtained, and death was certified as having been due to lung abscess, either caused by a septic pulmonary infarct (shown by the pain in the chest five days previously) or rupture through diaphragm of a subphrenic abscess. In the second case the diagnosis lay between an acute appendicitis, a ruptured gastric ulcer and, less probably, an ectopic pregnancy. At operation it proved to be a perforated stomach ulcer, the result of the lifting of a heavy tub.

43 *Normal Weight of Schoolchildren. J. E. L. Camescasse.—p. 113.
44 **Backward Development of the Bowels.* J. Comby.—p. 150.

43. **Weight of Schoolchildren.**—This article analyzes the data at a rural sanatorium and orphan asylum for Paris children; 2,571 boys and 2,506 girls were weighed at regular monthly intervals. Camescasse deduces from his statistics a set of diagrams showing the normal weight at different ages. For example, three girl babies weighing, respectively, 2, 3 and 4 kg. at birth, at the age of 16, each developing normally, should weigh, respectively, 39, 49 and 59 kg. Three boys weighing 2, 3 and 4 kg. at birth, at 16 should weigh 36, 49 and 62 kg. A girl weighing 14 kg. at 4 should weigh 19.1 kg. at 7; 27 kg. at 11; 40 kg. at 14, and 56 kg. at 20. By comparing the actual weight with the standard weight for the age we can detect possibly latent disease, and if the weight does not increase proportionately under hygienic conditions, the outlook is less promising. The two charts he has drawn for girls and boys, and here reproduces, are proving very useful standards for this purpose.

44. **Infantilism of the Intestine.**—Comby does not approve of Stoos' statements in regard to infantilism of the bowel. The fourteen cases he described do not require this label as they fit into the ordinary picture of infants debilitated by digestive disturbances or repeated gastro-enteritis.

52 Adhesive Plaster Occlusion Treatment of Lupus. Chateaubourg.—p. 174.
53 Appendicitis with Pseudomyxomatous Diverticulum. Villar.—p. 175.

48. **Emotive Psychoneuroses.**—De Fleury agrees with Dupré that besides neurasthenia and hysteria we must accept a third group of psychoneuroses, the emotive type, a constitutional or acquired *émotivité*. They have been classed hitherto mostly as traumatic neuroses, but the traumatism merely reveals or aggravates the constitutional instability. The train of symptoms from loss of balance in the circulatory, respiratory or digestive system, the tremor, the disturbance in the rhythm of the heart beat, the exaggeration of the reflexes—all this represents an enormous total of automatic neuromuscular activity which has nothing in common with the clinical exhaustion of neurasthenia. The spasmodic constriction of the muscles of the neck, and local spasms elsewhere distinguish the emotive psychoneuroses from hysteria. These two conditions are not only distinct but are separated by a deep chasm, the chasm which parts honest veracity from a morbid tendency to falsehood. With the emotive psychoneurosis the subject is ashamed of his symptoms and seeks to conceal them, while with hysteria, the subject seeks to display them theatrically, and the symptoms vanish when there are no longer any witnesses. This conception of the hyperemotive constitution clears up at once the puzzling field of psychoneuroses. They all fall naturally into the three classes: neurasthenia, hysteria and the emotive constitution, sincerity being an attribute of the latter in distinction from hysteria.

49. **Meningitis Among the Troops.**—Dopter relates that epidemic meningitis occurred in the *zone des armées* in the proportion of 0.42 per thousand men in 1915; 0.18 in 1916, and 0.15 in 1917. Most of the cases were in the training camps, the infection being brought in by new arrivals from regions where a few cases had been observed; the fatigue of the trip and the chilling on the way were certainly predisposing factors. The disease presented an endemic character, the cases were scattered at relatively distant points, but occasionally six or eight sick or carriers were found at one point. Prophylaxis was carried out as in times of peace by isolation of the sick, and isolation of the contacts (men under the same roof or in the same shelter) until they were all examined and found free from meningococci. Not many carriers were discovered.

60 *Leukoplasia. G. Railliet.—p. 1333; (id.)—p. 1336.

56. **Suprarenal Insufficiency in the Troops.**—In the case described a man of 26 was vaccinated against typhoid and this upset the unstable balance of latent disease of the suprarenals. Acute suprarenal insufficiency followed. Sergent, in the discussion that followed Satre's report, called attention to the increasing prevalence of symptoms of suprarenal insufficiency in the men on active service. The conditions of trench life tend to depress suprarenal functioning, and men with weak suprarenals suffer most. He queries whether this may not be an important element in the clinical picture of shock, and whether some of the *shockés* might not benefit from immediate and systematic suprarenal treatment.

60. **Buccal Leukoplasia.**—Railliet found leukoplasia in 135 out of 409 men at the front. His experience suggests that inherited syphilis may be incriminated in certain cases. The influence of smoking is undeniable, but it seems to act only on a pathologic foundation.

Lyon Chirurgical

November-December, 1917, **14.** No. 6

61 *Surgery at the Advanced Stations. C. Viannay.—p. 921.
62 *Infection of the Pleura with Chest Wounds. J. L. Roux-Berger and A. Policard.—p. 969.
63 *Film Dressing for Wounds. A. E. Robert.—p. 1048.
64 *Tardy Resection of Joints. G. Jean.—p. 1055.
65 Lengthwise Wounds of the Knee. R. Leriche.—p. 1079.

61. **Surgery at the Advanced Posts.**—Viannay remarks that surgery at the advanced posts has shown a constant evolution but that now, at the fourth year of the war, it seems to have reached a plane where the great principles are firmly estab-

lished. The surgeons at various scattered posts seem to have evolved these principles almost independently and simultaneously. This concordance guarantees the great verities involved: early and complete excision of all devitalized tissue, and then closing up the wound—all wounds, wounds of soft parts, joints, fractures. Immediate suture is the aim, and rapid recuperation. The majority of the wounded are healed in two or three weeks, many others, including extensive fractures, are healed in two months. He operated in 400 cases during a quiet period and sutured at once completely in 222 cases, partially in twenty-eight others. There was no need to open up the suture except in nine cases. The primary suture therefore was a success in 96 per cent. of 222 cases. With fractures, primary suture may be relied on if the projectile merely hit the bone, but if it traversed the bone, primary suture cannot be counted on with so much confidence.

62. **War Wounds of the Chest.**—Seventy-nine pages, with twenty-seven illustrations, are devoted to emphasizing the importance of applying the same general principles to chest wounds as to wounds on the limbs. The fractured rib should be removed, but it is impossible to excise all the devitalized lung tissue. It should be sutured, and the skin sutured. When this prompt and thorough débridement has not been done, the pleura grows thick and hard and outer portions of the lung harden into a kind of shell, while lesions of the acute bronchopneumonia type develop in the lungs. Sixteen of these old cases are reported in which the suppurating pleura was excised or decorticated, and the cavity drained and disinfected. Nine were cured by the intervention; the others were too debilitated to rally.

63. **Film Dressing.**—Robert mixes 100 gm. of paraffin, with a melting point of 48 or 49 C., with 3 gm. natural gutta percha, and uses this for a hot film dressing. The gutta percha permits a temperature of 80 C. without its burning the tissues, and wherever a film dressing is indicated, that is, he says, for large dry wounds, this dressing is proving very useful.

64. **Tardy Resection of Infected Joints.**—Jean has operated in sixty cases one or two months after the war wound, and he here holds the mirror up to these experiences. Good results were obtained almost always with the shoulder, but the wrist seldom is left with much capacity for movement. With the elbow, the outcome depends mainly on the postoperative care. In his ten hip cases, 80 per cent. of the men died. With an old discharging fracture of the knee, with fever and bad general state, he advises amputation, as also when the lesion extends over an area more than 10 cm. in length, and when the tibia is mainly involved in the injury. His experience testifies to the advantages of resection when the general state permits. For simple ankylosis with fistula he advises merely curetting and heliotherapy.

68 *Deep Palpation of the Stomach. L. Pron.—p. 139.
69 *Prophylaxis of Venereal Disease. Bourdinière.—p. 141.

66. **The Oculocardiac Reflex during Shock.**—Summarized in the Paris Letter, p. 1021.

68. **Deep Palpation of the Stomach.**—Pron describes the technic with which he has often found it possible to determine the lower margin of the stomach, the patient reclining supine and breathing deep. The palpation is done with the radial margin of the hand in semipronation during the patient's expiration.

69. **Prophylaxis of Syphilis, and Medical Secrecy.**—Bourdinière presents a number of arguments based on his daily practical experience as medical officer to a regiment of heavy artillery. The men are from southern France and northern Africa, and 50 per cent. of the creoles have long had syphilis, as also 6 per cent. of the other men. In civilian circles every effort is made to respect the desire for secrecy in cases of venereal disease, but every soldier who goes for treatment to the special venereal disease hospital is certain that every one in the company or the battery will know of it. Hence both officers and privates try to conceal their infection and neglect treatment. The man's card record also shows his infirmity to all who read it, thus annulling the efforts at secrecy by some of the medical officers through whose hands he has passed. Bourdinière's daily experience confirms the disadvantages of this lack of secrecy and the harm wrought by it, the men losing their confidence in the physician. Among the measures he suggests to correct this is that the medical inspection should be private, apart from the eyes and ears of others. The man's card should not specify that he has venereal disease. This information should not be given to any one except the superior medical officer. The venereal hospital services should form part of the general hospital, to avoid any stigma. Bourdinière adds that greater use should be made of the natural curiosity of many men, officers and privates, as to the damages that may be wrought by syphilis and gonorrhea. Moving pictures portraying them might be shown the men two or three times a year, by orders from headquarters. In conclusion he remarks that progress would be realized if the commanding officer of the locality where the infection was contracted were notified by the regimental physician so that the authorities could be on their guard, but specific denunciation of the house is impracticable.

71 The Fifth Cusp. E. Jeanselme.—p. 116.
72 Intramuscular Injections of Quinin in Malaria. Leenhardt and T. Tixier.—p. 119.

70. **Bone Grafting.**—Bérard refers to grafts to repair gaps in the tibia left by war wounds. If sequesters are left, with plenty of periosteum, there may be spontaneous regeneration of bone tissue. In three cases a sequester 7 or 10 cm. long, protected against necrosis by Carrel irrigation or other means, enabled regeneration so extensive that in from five to eight months a solid callus formed restoring the complete use of the leg. If this has not occurred in the course of eight or twelve months he then resorts to bone grafting. He takes the graft from the tibia itself, instead of sacrificing a sound bone, and has always been successful in this line. In two of his five cases, however, there was residual infection, requiring reopening of the wound and Dakin sterilization, but this did not interfere with the final consolidation. He gives illustrations of the findings at different intervals. The graft was split off from the tibia above or below the gap, cutting it to fit exactly into the space, the ends pointed or beveled to fit into the bone above and below. Some of the illustrations show the man standing on the grafted leg, holding his other leg up in the air.

76 Imported Malaria. M. Blatin and H. Paillard.—p. 84.
77 Paradoxes of Odors. P. Voivenel.—p. 88.

75. **Epinephrin Functional Test of the Heart.**—Loeper and his co-workers here give their conclusions from prolonged study of 100 cases before and after administration of epinephrin. This induces vasoconstriction which raises the blood pressure, thus throwing extra work on the heart. The sound heart responds with energy, and radioscopy shows slight if any change in the outline of the heart an hour later. A weak heart dilates at once and the dilatation persists some time. This indicates weakness of the myocardium, either of the muscle itself or the innervation, simple exhaustion or a valvular lesion. The dilatation is most pronounced with mitral disease. With aortic insufficiency, the aorta may become dilated under the epinephrin test while the apex region shows no change. The test dose of epinephrin is 1 mg., and the subject has to keep absolutely still, against the table used in

the test. The radioscopy is repeated three times at half hour intervals; the findings at one hour are the criterion. The normal heart shows a very slight shrinking of the outline after an hour and a half, testifying to the secondary constricting action on the musculature of the heart.

78. **Neuroses.**—Nägeli remarks that nowadays the most important thing in the field of internal medicine is a good knowledge of the neuroses, and in nothing else are there so many blunders made in diagnosis and treatment. Symptoms are ascribed to hysteria or to neurasthenia and a grave organic lesion is overlooked, or, even more frequently than this, grave organic disease is assumed when the symptoms are merely of a functional nature. In study of the neuroses, the neurologic findings must be disregarded and the psychic condition determined as the basis for diagnosis and treatment. The more numerous and diverse the complaints of subjective symptoms, the more probable the assumption of a neurosis, and in all cases the early recognition of the neurosis and the return to work are greatly to the true advantage of the patient. He cites figures to the effect that five sixths of the cases of sciatica at Baden spas in 1917 proved to be merely neuroses, and three fourths of the cases of supposed heart disease at Nauheim, and in these cases the spa treatment is of no benefit. Nägeli's own experience further confirms that in a large proportion of cases of rheumatism the trouble is merely a neurosis. Physicians shrink from telling the patient that his trouble is merely a neurosis. Only the combination at the same time of dilatation, hypertrophy, murmurs and possibly changes in the pulse exclude a cardiac neurosis, as a rule, and even this combination only when it fits into the frame of a given valvular disease.

79. **Somatic Changes Under the Influence of Emotions.**—Frankhauser presents data from physiology and pathology to sustain the assumption that strong emotions may induce somatic processes in the brain, modifying the innervation of certain still unknown neurons and possibly also of the glands with an internal secretion. Hysteria, shell shock and certain other neuroses are accompanied by disturbance of this innervation. This disturbance may occur from purely physical or purely psychic causes, or from both. Psychotherapy acts by setting in play other emotions which are capable of influencing the morbid innervation processes, and hence are liable to influence purely somatic phenomena. Because some morbid somatic process can be thus influenced by psychotherapy, this does not justify the assumption that the morbid process is necessarily of a psychogenous nature.

80. **The Variations in Weight with Healing Tuberculosis.**—Jchok analyzes the weight findings in about 100 tuberculous French soldiers interned in a Swiss sanatorium. The course at the sanatorium averages sixteen months, and the food averages 3,370 calories a day. This includes only 80 gm. of fat. The men gained in weight at first but as they improved they lost considerably in weight. This, he explains, is merely the casting off of the superfluous fat and is not a cause for alarm. As the men resumed exercise and work, the added fat was lost; as there was no return of symptoms, this must be regarded as merely the organism adapting itself anew to the conditions of life. The cicatrization of the infected areas in the lung deprives the body of that much functionally capable tissue, and the circulation and total metabolism are reduced in proportion, and the body gradually settles into a physiologic balance.

81. **Bacteria Carriers.**—Silberschmidt discusses the importance of carriers with epidemic meningitis, diphtheria and typhoid according to the findings at the Hygiene Institute of the University of Zurich. There have been a number of small epidemics of meningitis in barracks in Switzerland since 1906. The largest number was eleven in any one epidemic, and the cases all developed within seven or ten days. Carriers were found in from 10 to 30 per cent. and more of the men in the environment, mostly with mild catarrhal inflammation. These and other data cited justify the conclusion, he asserts, that carriers are not the main factor in the development of the disease. The large number of carriers is out of all proportion to the small number of cases. Predisposing factors are evidently mainly responsible. With diphtheria, on the other hand, carriers play an important part in the distribution of the disease, and they are comparatively few in number. It is of indispensable importance to see that convalescents are freed from diphtheria bacilli before they are released. The time and efforts required to free the convalescents from the bacilli are well spent. Typhoid convalescents and carriers must be kept under control until free from typhoid bacilli. The problem of carriers can be solved only by the working together of the hospital, the general practitioner, the bacteriologic laboratory and the hygiene institution, adapting their measures to the individual case and epidemic.

82. **Postoperative Psychoses.**—Tramer reports two cases which confirm the generally accepted view as to the benign nature of these disturbances, particularly when patients can be given specialist treatment. In both his cases there had been such extreme dread of the operation that this evidently cooperated in the production of the psychosis. He adds that surgeons might do well to warn the family of a possible postoperative psychosis when such abnormal dread is encountered.

83. **Cause and Prevention of Goiter.**—Hunziker concludes his long study of the prevalence of goiter in different regions and altitudes of Switzerland. The data he presents apparently sustain his theory that goiter is a functional hypertrophy of the thyroid caused by the effort of the organism to make up a deficit in the iodin supply. As the iodin naturally is supplied in the food, goiter is prevalent in regions where the vegetation lacks the standard proportion of iodin. Iodin-containing manure in the regions where goiter is endemic might supply the vegetables with the needed iodin, and thus exterminate goiter. The main goiter regions he found are at a moderate altitude, from 600 to 1,000 meters; above and below this, goiter is less prevalent. In one comparatively exempt canton he ascertained that the cooking salt used had an unusually high iodin content. In certain years goiters develop more numerously than in others. This may be due to rains which wash the salts out of the soil. A sandy soil yields them up more readily to the rains. In a rainy season, also, the vegetation grows less luxuriantly and takes up less of the salts in the soil. At altitudes above 1,000 meters, the vegetation grows so luxuriantly when it gets a chance to grow that it works deep into the soil and takes up the salts. It is significant further that the comparatively exempt cantons have their main rainfall in the autumn, instead of in the spring as elsewhere. In short, he declares, goiter is an adaptation to an iodin-poor diet. The iodin-poor vegetables are what connect goiter with climate and geological formations. The simplest way to remedy the poverty in iodin would be to have salt made with a small admixture of iodin. He suggests parenthetically that it had better be investigated whether the iodin in salt in bread may not be volatilized by the heat of the baking. A year of such "fertilizing" of human beings on a large scale by adding iodin to the salt would go far toward solving the problem. A still simpler plan would be to have the salt taken from the salt springs in the comparatively exempt canton of Waadt sent to a canton where goiter is very prevalent, exchanging it for the salt made from the iodin-poor salt springs in the latter canton. All the testimony and arguments presented emphasize the importance of insuring an ampler iodin intake in regions where goiter is prevalent.

Archivos Españoles de Pediatria, Madrid

January, 1918, 2, No. 3

86 *Fractures of the Skull. E. S. Ordoñez.—p. 1.
87 Hidroa in Children; Two Cases. E. de Oyarzabal.—p. 16.
88 *Evils of Sweat-Shop System. R. Pinilla.—p. 20.
89 *Calculi in Child's Kidney. P. Cifuentes.—p. 26.

86. **Fracture of Skull in Children.**—Ordoñez gives the details of six cases of fracture of the skull in children from 4 to 12 years old, with the necropsy findings in one case. All the other children recovered. The child's brain can stand traumatism remarkably well in comparison to the child's great susceptibility to other pathogenic influences, such as meningitis. But at the same time this tolerance is not equivalent to an absolutely benign course. The prognosis depends in large measure on whether the brain is exposed or not, but even the simple closed fractures, especially in the frontoparietal region, may entail jacksonian epilepsy. With a closed fracture, abstention should be the rule; the symptoms from concussion and even focal symptoms may subside spontaneously, as in one of the cases described. Intervention is required of course if the symptoms indicating pressure on the brain are grave and prolonged, or there is paralysis or epilepsy. Even with a compound fracture, if the opening is small, abstention may prove successful, as in one of the cases reported. With extensive prolapse of the brain, deep infection seems inevitable, and prolapse is liable to follow any attempts to enlarge the opening in the skull.

88. **The Sweat-Shop System in Madrid.**—Pinilla mentions in discussing home work for pay that this system is producing in Madrid an immense number of tuberculous children, while it prevents the normal development of the women and injures the population of the future.

89. **Kidney Stones in Child.**—Cifuentes was unable to determine whether stones or tuberculosis was responsible for the hematuria and pain in the right kidney of a boy of 7. He had been complaining of pain in this region for three years and the urine was turbid, but there were no signs of pronounced cystitis although there was fever at times. The urethra is too narrow in boys of this age to admit the cystoscope, but the response to the indigo carmin test was satisfactory, and the normal aspect of the other kidney was ascertained by an exploratory lumbar incision on the left side. Thirteen days later the right kidney was exposed and found full of pus, with five branching stones, and cystic dilatation, the ureter also pathologic. Ten days after the nephrectomy there was some hematuria for a day. He is convinced that nephrolithiasis in children is sometimes mistaken for or masked by bowel trouble. Uricemia is comparatively common in children from 2 to 8, the result of food too rich in nitrogen for their age. This predisposes to lithiasis, but it generally takes the form of sand which may pass off without pain, or it may accumulate in the bladder and form a large stone. Prophylaxis depends on the diet, and this is a most important problem in the hygiene of the child.

90 *The Adams-Stokes Syndrome. H. Ribeiro.—p. 441.
91 Lice in Transmission of Smallpox. A. Ferrari.—p. 443.

Jan. 19, 1918, 32, No. 3

92 *Medicolegal Aspect of Findings in Air Passages. O. Freire.—p. 17.

90. **Adams-Stokes Disease.**—The workingman of 68 had a ventricle beat of only 14 and sometimes it dropped to 11; at these times there were attacks of syncope and epileptiform seizures. The positive Wassermann called for specific treatment, supplemented with trinitrin, atropin or spartein, and the pulse was gradually brought up to 24 in less than a month, after which there were no further attacks. The man is still in the hospital and doing well.

92. **Medicolegal Aspect of Foreign Bodies in Air Passages.**—Freire found a small snail shell impacted deep in a bronchus in a cadaver taken from the bay. He deduced from this that the man must have aspirated the shell in drowning, and that the scene of the drowning was probably close inshore where this variety of shell abounds. He cites other cases in which a leaf, part of a flower, seed or grain in the air passages revealed not only the probable location where the death occurred but also suggested the approximate date.

Cronica Medica, Lima

January, 1918, 35, No. 655

93 Diagnosis of Duodenal Ulcer. E. Odriozola.—p. 1.
94 *Echinococcus Cysts in the Lungs. A. Corvetto.—p. 7.
95 The Pseudo-Beetles of Peru. (Algunos nuevos pseudomeloides.) E. Escomel.—p. 10.
96 *Meningeal Suprarenal Insufficiency. A. S. Moreno.—p. 17.
97 *The Tear Sign of Actual Death. R. A. de Toledo.—p. 20.

94 **Echinococcus Cyst in Lung.**—At necropsies of persons with pulmonary tuberculosis, Corvetto found in three cases a primary echinococcus cyst in a lung, the spleen or the liver, which had escaped detection during life. He here describes a case of primary echinococcus disease of the lung, diagnosed during life. The symptoms suggested incipient pulmonary tuberculosis, with recurring slight hemoptysis and cough, the sputum scanty and mucous. After four months of this the man felt sudden suffocation and coughed up the membrane of a hydatid cyst, about the size of an egg. All the symptoms permanently subsided. In a fatal case of pulmonary tuberculosis Corvetto found at necropsy two echinococcus cysts in one lung which had caused no reaction on the part of the parenchyma and had escaped detection during life.

96. **Meningeal Form of Suprarenal Insufficiency.**—Moreno describes a case of severe febrile and toxic gastro-intestinal disturbance in a frail little girl of 7. It proceeded to include meningeal symytoms, unequal pupils, Kernig's sign, vomiting, cephalalgia, etc., with tachycardia, low blood pressure, uncontrollable vomiting, white dermographism and extreme prostration. Moreno accepted this set of symptoms as the pseudomeningeal form of suprarenal insufficiency, and gave the child a subcutaneous injection of 1 mg. of suprarenal extract. There was no change the next day in the apparently moribund child but he repeated the injection morning and evening, and the following day marked improvement was evident and the child was soon fully convalescent. The suprarenals probably were not strong, and the toxic action from the poisonous products generated during the severe digestive upset had evidently induced acute insufficiency on the part of these glands.

97. **The Tears in Test of Actual Death.**—De Toledo has tested on 180 cadavers and 2,000 living persons Lecha Marzo's test and has found it almost invariably positive in actual death. The test is merely the change of the reaction to litmus of tears. In the living the reaction is alkaline, and it veers to acid after death. De Toledo never found the reaction acid in tears from the living. It was not always constant in the cadavers, but when found can be relied on. The tears were always alkaline in 542 males and 537 females of all ages and conditions, and also in 1,104 patients in the eye infirmary with various eye diseases. With actual death the reaction veers to acid in from half an hour to seven and a half hours. The change seems to be slower when the weather is cold.

Repertorio de Medicina y Cirugia, Bogota

February, 1918, 9, No. 5

98 Training the Character. P. Rincon.—p. 229.
99 *Treatment of Infected Wounds. L. L. Pereira.—p. 257.

99. **Treatment of Infected Wounds.**—Pereira has been serving in the American ambulance in France and more than 3,000 wounded men have been cared for in his service. He has also worked with Carrel and Depage, and is now conducting a course of instruction for American surgeons on their way to organize hospitals at the front. The main principles taught are that local disinfection has to be more mechanical than chemical; that germs become accustomed to a disinfectant so that a change is necessary; that air usually should be allowed to reach the wound, and that in dressing a wound gloves and forceps should be used for each separate case as carefully as for an operation. Of the various methods of treatment he describes with illustrations, he commends to the general practitioner the soap method. He says it is a common practice of veterinarians in South America to apply

toms of stenosis should warn of trouble. Direct bronchoscopy is indicated at once; it may prove possible to aspirate through the bronchoscope the contents of the gland that have broken through into the bronchus. When the tuberculous glands are in the anterior mediastinum, they can be reached as a rule only by removing the sternum. Dalziel reported 3 cases of this kind in 1915. In one case a suppurating gland was found close under the arch of the aorta. In 14 of the tabulated 20 cases the suffocation occurred without warning, and 9 of the patients died. One child of 5 was intubated and tracheotomized for assumed diphtheria, but he finally coughed up the tuberculous gland masses and recovered. One boy was treated with artificial respiration, and this forced the coughing up of the masses. One child only 11 weeks old had the tendency to suffocation keep up for five days, and then it coughed up a tuberculous gland. Two of the patients were men; tracheoscopy showed the trachea compressed. The outcome in these cases is not known. In 2 other men enlarged glands had perforated into both trachea and an artery, and fatal hemoptysis followed. There is no doubt that if the trouble had been differentiated earlier, more lives could have been saved by direct tracheoscopy, etc. Tracheoscopy is especially useful in cases developing gradually, as the best mode of treatment can then be determined with confidence. For children under 6, tracheotomy is indispensable for tracheoscopy, but for older children and adults the natural passages suffice.

128 Transverse Presentation: Frequency and Causes. Drejer.—p. 153.
129 *Tests of Kidneys with Hypertrophied Prostate. F. Bie.—p. 167.
130 *Diphtheria from Epidemiologic Standpoint. P. M. Holst.—p. 186.
131 *Fever with Sarcoma. C. Schiøtz.—p. 202.
132 *Hereditary Ataxia. J. Henrichs.—p. 207.

129. **Tests of Kidney Functioning with Hypertrophied Prostate.**—Bie gives the charts from twelve *prostatikers* showing the diuresis, the elimination of urea in the urine, its specific gravity, albumin content, and the findings with the phenolsulphonephthalein test of kidney functioning—all systematically recorded daily or at brief intervals. The charts all confirm Pilcher's warning that the kidneys have been suffering from the retention and that they experience a kind of shock when the retention is overcome and the urine passes off normally. All the tests showed the depressed functioning of the kidneys, reaching its height two or three days after the retention had been corrected. After this the kidneys rapidly recuperated, usually within eight days, but not until longer than this if the kidney was pathologic. The practical conclusion from his data is that prostatectomy should be done in two sittings, first relieving the retention, and then allowing the kidneys time to recuperate before proceeding to the actual prostatectomy. The data here presented supply the scientific basis for the two-step method, the advantages of which have already been demonstrated empirically.

130. **Diphtheria.**—Holst found from two to eight carriers among three groups of recruits numbering from 163 to 385 men. Others have reported recently from 2 to 9.2 per cent. in three groups of healthy schoolchildren numbering 341, 277 and 967. Holst also tested the antitoxin content of the [illegible] 100 healthy persons, and in diphtheria patients and convalescents. He tabulates the findings and analyzes local statistics. All tend to demonstrate, he says, that an epidemic of diphtheria immunizes the community. Only a few develop the disease, but large numbers become infected. They bear the infection without its giving rise to sickness or symptoms. In this respect diphtheria resembles tuberculosis. After a longer or a shorter interval, this immunity wears off and the way is opened for another diphtheria epidemic. The assumption that the immunity conferred by an epidemic of diphtheria lasts for about twenty years conforms to the epidemiologic facts recorded for diphtheria.

131. **Fever with Sarcoma.**—A woman of 25 entered the hospital on account of repeated chills and pseudo-intermittent fever for three weeks. There were also pains in one side and a transient exanthem. The fever kept up, with high peaks and numerous chills; the abdomen was tender and there were signs of bronchitis. Necropsy disclosed sarcomatosis involving the glandular system, periosteum and dura mater, left tonsil, stomach and ileum. Among Bull's twenty cases of sarcomatosis, fourteen were febrile and these were the younger patients. Only one case of metastasis was found in the six afebrile cases. Two other Norwegian cases are known, both in physicians. In one, long persisting evening temperature of 39.7 C. was explained by a retroperitoneal sarcoma. In the other, a melanotic sarcoma in the kidney had caused regularly returning chills and fever.

132. **Hereditary Ataxia.**—Henrichs reviews the literature on the subject of Friedreich's disease and reports with illustrations the case of two brothers, adults, one 11 years older than the other, both with typical hereditary ataxia. Both are feebleminded, as also one sister who shows no signs of ataxia. The other eleven children in the family are normal.

*134 *Pharmacology of Iodids. J. Buchholtz.—p. 139.*
135 Dosage of Optochin. V. Scheel.—p. 150.

133. **Swine Erysipelas in Man.**—Svith has encountered six cases, all in men who had recently slaughtered a hog with swine plague. The incubation period ranged from twenty-four to thirty hours. Pain was the first symptom to attract attention, but the exanthem and the lymphangitis are the most characteristic features. The blotches grow to be about the size of a cent; they are reddish at first but change to a bluish gray. The nearest joint is liable to swell and be painful, and the disease displays a tendency to recurrence. Under serotherapy the whole subsides in a few days, while without it the disease may drag along for from two weeks to five months.

134. **Pharmacology of Iodids.**—Buchholtz has been conducting experimental research on the absorption of iodids from the digestive tract, their passage into the blood, and elimination in the urine. He found that they do not seem to be absorbed in the stomach at all. The iodid in the blood rose after each dose and soon dropped again, showing that to keep the organism under the influence of the iodid requires numerous small doses over the entire day. The elimination in the urine reaches its height in about two hours, but the length of the interval depends on the promptness with which the stomach contents are passed along. It makes a great difference whether the iodid is taken on an empty or a full stomach. On a constant diet, the iodid does not seem to modify the viscosity of the blood; conflicting statements have been based on tests without control of the diet. Buchholtz' extensive research on the influence of iodids on the heart action failed to reveal any change in the blood pressure or pulse rate even when the blood contained amounts of the iodid far beyond the therapeutic dosage. When the iodid content of the blood reached a very high figure, the heart action was depressed and the blood pressure dropped, as the blood was thus rendered hypertonic. The therapeutic action of iodids in circulatory disturbances thus has no experimental basis. Benefit from it suggests a syphilitic origin for the disturbances.

RECONSTRUCTIVE SURGERY IN WAR TIME *

F. C. KIDNER, M.D. (DETROIT)
Captain, M. R. C., U. S. Army
ENGLAND

The energy and enthusiasm of Sir Robert Jones are responsible for the establishment in the British Isles of fifteen or twenty large, well equipped orthopedic hospitals for wounded soldiers. Over these, Sir Robert exercises a general supervision, and in them he instructs the various members of the staffs in the details of reconstructive work among the wounded. During the past nine months, it has been my good fortune to be stationed in charge of a service at one of the largest of these centers, that at Shepherd's Bush, London. During that time, I have had an opportunity of seeing and of treating large numbers of patients who, in private life, would be considered permanent cripples, but here, through the stimulating teaching and with the wise help of Sir Robert Jones, are being returned to usefulness.

The Shepherd's Bush Hospital has 1,100 beds, and is fully equipped with departments for after-treatment, massage and electricity, a gymnasium, and curative and productive workshops. It is in charge of a group of able men all specially trained in orthopedic surgery, or in one of the supplementary specialties. In my own service, I have had the opportunity to apply the various methods which the necessities of war surgery have added to those of civil life. In the light of this experience, I feel justified in attempting to sketch some of the problems that arise from war damage to bones, joints, muscles, connective tissues and nerves, and some of the methods of treatment that have been found to be of value.

SEPSIS

Fundamentally, both the problems and the methods of treatment are the same as those of orthopedic surgery in civil life. In detail, the two are radically different. This is due to several factors, first of which stands sepsis. Nowhere in private life do we meet such persistent and severe sepsis as constantly occurs among the wounded. Second in importance comes scar tissue. The great destruction of soft parts, and the active sepsis of wounds, combine to create enormous masses of dense, extremely tough, fibrous tissue. Third, the crippling incident to wounds is often so widespread and so severe that very difficult problems of judgment arise in laying out a plan for the restoration to usefulness of the patient. For example, it is far more important to preserve even badly crippled fingers on the left hand when the right hand has been wholly lost, than it is when the right hand is still useful. In this connection, let me say that our experience leads us to believe that a very poor natural leg and foot is better than an artificial one, and that any natural hand and arm, no matter how bad, is better than an artificial one. Fourth, the great length of time required to get results puts a heavy tax on the cardinal virtue of patience in the surgeon, and on the mental and moral fiber of the war weary soldier.

The greatest number of our cases are those that involve bone injury, and these come to us in two classes, the recent and the old. Of the former there are few, of the latter there are very many. The recent fractures reach us after the primary operation for drainage has been done, and the adjustment of the fragments effected. All of these are actively and violently septic, and the greatest difficulty in their treatment lies in proper fixation and alignment, with satisfactory drainage. This is, however, perfectly possible, and can always be accomplished, except in the rare case in which amputation is necessary. Indeed, fixation in perfect alignment is the most important feature in the treatment of sepsis in compound fractures. Never is it necessary to let the fracture take care of itself while the sepsis is treated. After fixation, thorough and complete drainage and counterdrainage are the most important measures. Carrell's technic is useful, but not infallible. It undoubtedly hastens the cleaning up of wounds when drainage is satisfactory. In our hands it will not overcome sepsis without efficient drainage. It seems probable that the important factor in irrigation technic is the prevention of blocking of wounds by drying of the discharge. No matter what technic is adopted, or what solution used, the prevention of drying, careful attention and thorough drainage and counterdrainage are the cardinal principles.

During the active stages of sepsis of bone injury, the most satisfactory fixation of the parts can be obtained by the use of various simple splints. The most important of these is the Thomas knee splint, which, in different sizes, is easily adaptable to the leg or the arm. It can be bent to any desired shape, and provides excellent extension. It is easy to attach to it cross supporting bands of cloth, which can be removed one at a time without disturbing the position of the fracture, and allow easy access to the wound. When its ring is properly fitted, efficient counterextension is obtained against the tuberosity of the ischium, or against the ribs. When properly applied, it provides perfect fixation and allows almost any degree of traction. It can be adapted by simple changes in shape or position to any fracture below the neck of the femur in the leg, or to any fracture in the arm. For example, a fracture of the lower third of the femur can invariably be brought into alignment by bending the splint at the knee to from 20 to 40 degrees. When of the upper third, it may be adjusted by abducting the whole splint. If very strong traction is necessary in reduction of the deformity of the femur, this can be obtained by tying the lower end of the splint to the foot of the bed, and raising the foot of the bed from 12 to 18 inches, thus adding the extension force of gravity through the pull of the body weight. This splint is typical of the simplicity of apparatus that has proved so useful in the common septic compound fracture.

---

* From the Military Orthopedic Hospital, Shepherd's Bush, London, England.

The many forms of weight and pulley support and extension are useful in certain rare cases, but as a rule they are more cumbersome and difficult to manage than are the simple splints.

Under the treatment outlined above, it has been found that sepsis clears up rapidly, and that union in good position is invariably obtained.

BADLY UNITED OR UNUNITED FRACTURES

The second great class of bone injuries which reaches us are badly united or ununited fractures of months' or even years' standing. Most of these still have discharging sinuses, due to necrotic bone and metal fragments. Some of them never were properly reduced. Others were originally well reduced, but through the exigencies of the hospital service, in passing from surgeon to surgeon and from hospital to hospital, have gradually assumed distressing deformities. Sequestrums, sepsis, scar tissue, loss of joint function, all complicate their treatment.

Sequestrums appear in almost every case, as a result of infection. These as a general rule should be left alone until every sign of active sepsis has disappeared, and they are thoroughly separated from surrounding living bone. Removal of sequestrums must be done with most careful aseptic technic, and with an absolute minimum of trauma. A large incision of the soft parts is to be preferred, because in spite of the fact that it opens more new channels to superficial infection, it gives a view of the field of operation, which allows a minimum of bone damage. Uninfected and living bone must not be cut or scraped if it is possible to avoid it. After the removal of all dead bone, thorough drying and cleaning of the whole wound is necessary. A good technic is as follows: The dead bone is removed as gently as possible, all hemorrhage is stopped, the whole wound is dried with gauze, and alcohol is rubbed gently into all corners. This is followed with a little bismuth iodoform paste rubbed with gauze gently over all raw surfaces, and the excess removed. Sequestrectomy wounds that have been so treated may be closed tight and will break down less frequently than those in which the same technic is used without bismuth iodoform paste. Chronic wounds that have been "bipped," if they do break down, close again more rapidly.

In treating the joint that stiffens during the treatment of fractures, we have the same problems that we see in civil life. They are made worse, however, by the fact that attempts to mobilize stiff joints in these war cases frequently cause a flaring up of the original sepsis, even though it was a considerable distance from the joint. This is due to the pull exerted through muscle and fascia and the scar tissue, and has taught us that it is rarely safe to use force on such joints. Attempts at mobilization must always be gradual, and limited by pain or any sign of active inflammation. Therefore, it is best to depend on massage and exercises rather than on forcible manipulation. It is a comparatively simple matter in early fractures to prevent stiffness of adjacent joints by frequent and prompt passive motions. These can safely be begun as soon as the fracture has solidified sufficiently to prevent shortening. If the extension is removed for a few minutes each day, it can be carried out without removal of the splint.

Badly united fractures are of all degrees of deformity. Their treatment can best be considered under two heads, early and late. The early cases are those in which union has occurred but calcification is not firm from four to twelve weeks after the receipt of the injury. In this period it is almost invariably possible, by correct application of splintage and extension, markedly to decrease or even overcome the deformity. That is, although the union is apparently firm, it is really still plastic, and steady application of corrective force will mold it. This method should always be tried. When sepsis is not active in this early period, it is often safe and wise to manipulate under an anesthetic and restore alignment by this means, thus saving time. This forcible method, if carefully and gently done, does not stir up sepsis to any serious extent, but it is a measure that should be used with the greatest circumspection. Reduction by one of these two methods in the early stages of union is far easier and apt to be much more successful than is reduction by operative procedure in the late, thoroughly calcified stages.

The second class of firmly united deformed fractures almost invariably can be improved. The correction involves difficult and tedious operations, but is always worth while, because the disabilities that result from the mechanical disturbances of bone deformity are extremely trying. The key note of corrective operations is the thorough breaking up of the vicious union, so that the fragments can be molded gradually into normal position. If the breaking up of the union is complete, fixation in the corrected position at the time of operation is comparatively unimportant, because proper traction following operation will overcome extraordinary degrees of deformity and shortening. I have recently had a case of an oblique fracture of the lower third of the femur with posterior displacement of the lower fragment and 3½ inches shortening, which had been firmly united for a year at the time of operation. The union was with great difficulty chiseled free in the line of the old fracture, and forcible attempts were made to overcome the shortening with the aid of a Hawley table. The most that could be gained under the anesthetic with the application of great force was 1 inch. Therefore the bones were left in the bad position, the wound closed and the patient put to bed in a Thomas splint, with traction applied within the splint. Additional pull was obtained by tying the splint to the foot of the bed, which was raised 18 inches. In two weeks' time, the overlapping was completely overcome and perfect alignment and position obtained and held. The bone is now reunited in perfect position. Where the shortening is due to bowing at the site of a fracture, and not to overlapping, it can be overcome completely by simple osteotomy and forcible straightening at the time of operation. Proper traction will hold it. The results obtained by this method of osteotomy, followed by extension and fixation in all types of vicious union, have been so good that I have yet to feel the necessity for the use of any of the forms of internal splintage, such as bone plates, bone grafts, or pins. The added complication and dangers attending their use do not seem to be compensated by any corresponding improvement in result. The application of any form of internal splint often leads to a false sense of security, which engenders a neglect of proper external splints, with the result that the deformity recurs. In many cases the amount of violence needed at the time of operation to get position good enough to justify the application of an internal splint is so great as to do great harm. Sometimes, as in the case cited above, no application of force or manipulation will bring about such an immediate reduction.

Ununited fractures are far worse than they are in civil life. They are of all degrees, from simple fibrous union to gaps 3 or 4 inches in length. Absolute immobilization in good position is the key note of their treatment. Most fractures in which there is little loss of bone fail to unite because of improper fixation. Even after many months of nonunion they will often unite without operation if absolutely fixed. Syphilis has little bearing on the question of union among the men who come to us, as it is of extremely rare occurrence, if we may trust the Wassermann test.

In cases in which there is large destruction of bone, bone transplantation is invaluable for three reasons. First, it immobilizes; second, it provides a bridge along which bone cells may grow from the fragments; third, it connects together any small fragments of living bone or periosteum that lie free in the tissues. I have yet to see a bone transplant that showed any signs of proliferation. On the other hand, I have watched many transplants with the roentgen ray, and seen new bone creep gradually along the graft from the living bone at both ends, forming bridges with the graft as a trellis, gradually thickening and piling up until the graft is incorporated in a new sheath, and itself becomes incorporated as new bone. The view that the growth all occurs from the living fragments is confirmed by the fact that occasionally the graft will have to be removed after weeks or months because of low grade sepsis. Such removal does not necessarily interfere with the bridging process from the ends of the fragments, which afterward go on to union. Defects of bone 4 or more inches long are often successfully bridged by grafts.

Joint injuries and infections are those of civil life much exaggerated, and are of all sorts, from the clean penetrating wounds to the badly infected destructive lesions. Many are merely small fractures into the joint. There are also numbers of inflamed joints due to systemic infections from tonsils, teeth or intestine. These are purely civil problems, but are interesting because of the comparative frequency, on this side of the water, of bad tonsils, teeth and sinuses. The damp climate makes their treatment more difficult. Syphilis is less common as a causative factor than it is in hospital practice at home.

Most of the gunshot wounds of the joint come to us after thorough operation at the front. This has usually consisted of wide incision, removal of dead tissue and thorough lavage. In the simple penetrating wounds the joints have often been closed tight. Those that stay closed do remarkably well, and it is easy to restore function. This is particularly true in the knees and wrists. In many of the cases, too, in which much damage has been done, and drainage was necessary, the patients recover with some motion. These facts suggest a doubt as to whether joints are really so nonresistant to infection as we have thought in civil life. Even when drained joints become permanently stiff, they are more useful than an amputated limb. Primary excision of joints at the front may be necessary to save a limb, and sometimes give good results; but so far as we have seen them, they are not so useful as those that have been freely opened and drained. This is because after early excision union does not always occur. Nothing is more difficult to handle than such a flail joint.

STIFF JOINTS

Mobilization of stiff joints, whether the result of sepsis, of fixation, of nerve injury, or injury to muscles and tendons, still presents many problems to be solved. It is a safe general rule that, if there is no true bony ankylosis, and the cartilage is not completely destroyed, some degree of motion can be obtained. If this range of motion is small, it is apt to be continuously painful because of joint strain. If this pain is great, then a permanent arthrodesis in useful position is wise. This is especially true in the knee joint. The vast majority of stiff joints, however, can be brought to a useful range of motion. In obtaining this, our greatest standby is voluntary use of the muscles by the patient in attempts to use and move the joint. Unfortunately, however, because of complete fixation, of weak muscles, or of nerve injury, many joints cannot be voluntarily used. In them certain rules must be observed.

1. The painful, sensitive joint, no matter how old the injury, should not be moved. It should be rested absolutely, and its only treatment should consist in efforts to keep up the circulation and to improve muscle tone. Electricity, light massage, heat, are all useful in this connection.

2. A painless stiff joint should be treated with a minimum of trauma.

3. Gradual progressive force applied over a long period accomplishes more than does sudden, severe manipulation.

4. Stiffness in bad position should always be corrected, so that if we are to have permanent loss of movement, we shall have a useful limb.

The line of treatment adopted depends on the cause of the stiffness. Let us first consider the cases that are due to adhesions within the joint. If these are firm and many, two courses are open to us. First, the continuous application of force through some form of splint, whose action depends on the pull of gravity, the pull of an adjustable cord, or the pull of an elastic band. Examples of these for the knee are the simple inclined splint, bent, on which the thigh and knee rest, while the leg and foot are unsupported; the jointed posterior splint with a turn buckle; the Turner screw and the jointed posterior splint with a strong elastic band connecting the two parts and tending constantly to approximate the leg and thigh. All of these may be reversed to straighten a stiff bent knee. All are useful and require little attention. The second course is that of progressive forcible manipulation under an anesthetic, with fixation in each new position until the pain disappears. This process may require four or five anesthetizations, under no one of which should the movements be continued to a point at which great force is needed, or a violent reaction is set up. In my hands, this method has been the most successful. It takes time and great care, and must be accompanied by measures to keep up the tone of the muscles that act on the joint.

When adhesions are comparatively weak, and can be easily broken down, then one anesthetization under which the joint is put through its full range of motion only once (a point very wisely insisted on by Jones) may be thoroughly successful. In such cases no splint should be used, massage should be begun the same day, and active and passive motions continued immediately.

When stiffness of joints is due to injury of soft parts outside the joint, or to the formation of dense scar tissue following sepsis, gradual stretching is the only feasible method, unless something can be gained by dissecting out tendons or muscles that are bound down in scar. Fingers are most commonly stiff from this set of causes. Forcible manipulation here is valueless, as it simply tears soft parts and forms more scar tissue. Elastic traction will do wonders in flexing stiff, straight fingers. It can be applied by means of a leather glove, to the fingers of which are fastened elastic bands, which are made fast to a splint or plaster that hold the wrist hyperextended. It is best to attack the phalangeal joints in succession, beginning at the distal, the proximal ones being fixed meanwhile. In this way the successive segments can be pulled down till the fingers are curled up in the palm of the hand. This process must be very slow in order to stretch thoroughly the soft parts involved. If extension instead of flexion is the desideratum, then a flat, anterior splint can be applied to the successive joints as in gaining flexion, the elastic pressure being obtained by straps over the backs of the fingers. All treatment of stiff finger joints should be undertaken with the wrist in hyperextension. It is most important to keep up the power of the forearm muscles during this treatment by means of massage or electrical stimulation. If the stiffness is due to nerve injury and resultant trophic changes, then our efforts must be devoted to prevention of deformities, retention of the joints in good position, and preservation of the muscle power by electrical stimulation until the nerve supply is reestablished.

When stiffness is due to bony deformity or overgrowths, surgical interference to restore normal contours is primarily necessary. Such surgery is difficult, and its results are problematic.

NERVE INJURIES

Connective tissue formation is one of the most serious difficulties with which we have to deal. Almost all the wounds we see are badly scarred because of the sepsis and because of the great destruction of soft tissues. Masses of scar tissue lie in and around joints, in muscles, and around nerves and bone. Their vitality is low and they are extremely vulnerable to infection. In dealing with them, several principles must be observed. First, when scar tissue interferes with motion, it should be excised as widely as possible, and the fresh tissue brought together. Second, one should be sure that there is no latent infection in connective tissue before attempting any operation on bone or nerves, such as a bone graft or a nerve suture. Certain fixed periods of time after the healing of a wound have been laid down as sufficient to assure the disappearance of sepsis in scar tissue. In nerve cases this is often said to be from six weeks to three months, and in bone cases from six months to a year. Unfortunately, such periods are not always sufficient, and it is impossible to tell by examination when latent sepsis has disappeared. Gas gangrene and virulent sepsis have frequently occurred in patients operated on after a year or more from the time of healing. A useful procedure, and one that I have applied with success, is as follows:

In nerve cases, as soon as the wound is healed and the skin is clean, operation should be performed and the damaged nerve explored. Scar tissue should be excised and the cut ends of the nerve cleared. The wound is closed tight, or with a small drain, and left for ten days. If there is no sepsis, it is easy at the end of that time to do a second operation and suture the nerve. When a bone operation is necessary, such as a bone graft, one should wait till the wound is firmly closed and the scar has been more or less softened and mobilized by massage, perhaps six weeks or two months. Then one may operate and prepare the bone field, excising scar tissue. One should cut the channels for the graft in the bone fragments and do everything except the critical step, such as the fixing of the graft. Then one should close the wound and wait ten days. If there is no flare up, the operation can be safely completed. In either case, if there is a flare up after the first operation, comparatively little harm is done, and the area can be efficiently drained without fear of nullifying the results to the patient. This procedure involves the discomfort of two operations, but is, I am sure, the only safe way.

Peripheral nerve injuries are extremely common in war wounds. They are of all types, complete division with much loss of substance, partial division, or irritation from surrounding scar. They may be single or multiple. Certain nerves, from their exposed position, are more commonly involved. The lesion may be anywhere from the spinal cord to the periphery. Treatment depends on the type of the injury, and this can be determined only by the most accurate and careful diagnosis based on a thorough anatomic knowledge. Electrical examination with the faradic and galvanic current is absolutely essential, and provides the only means in many cases to distinguish between true organic lesions, and functional paralysis. It is essential that the surgeon who comes in contact with these cases shall familiarize himself with the distribution of the nerves, both motor and sensory, to a degree that is rarely done in civil life. A careful review of nerve and muscle anatomy will be of the greatest value to any surgeon who is to treat war wounds. Treatment falls into two classes, the operative and the mechanico-electrical.

Complete lesions of nerves, when due to actual cutting or of scar formation within the nerves, or to constricting bands of fibrous tissue, must be explored, and sutured, resected or cleared. Partial and irritative lesions are usually better left surgically alone, as the tendency to recover spontaneously is very great if any fibers of the nerve trunk are still intact. Recovery in all cases is much aided by electrical treatment, which maintains the tone of the muscles, and by splints and massage, which prevent deformity, and maintain the flexibility of the joints. Nothing is more discouraging than to see the muscles supplied by a recovering nerve begin to regain their power, uselessly, because they have to pull against the resistance of deformed rigid joints.

There are exceptional partial lesions of nerves, in which scar tissue pressure causes severe and continuous pain, that must be operated on. Occasionally it is even necessary to do a section of the nerve above the point of injury and resuture it. These cases of so-called causalgia are among the most trying that we see, and resemble closely the severe cases of trigeminal neuralgia.

The prognosis of nerve suture grows worse in proportion to the length of time after the injury; but nerves will recover if sutured, very long periods after they are cut. After suture, the length of time for recovery varies from six months to two years, the musculospiral usually being the quickest, and the sciatic the slowest.

The technic of nerve suture should be as simple as possible. A long incision in the course of the nerve, isolation of the nerve above and below the wound in normal tissue, and dissection of the nerve from these starting points through the scar tissue to the point of damage. One should never try to find a nerve in scar tissue at the point of injury. The nerve trunk should be handled as little as possible, and it is safer to handle it, when necessary, with the fingers, or with mouse-toothed forceps, which grasp only the areolar tissue of the nerve sheath, than it is to use smooth forceps, which slip and squeeze. When the nerve ends are found, they should be grasped in turn at the tips, and then serial sections made part way through the trunk with a sharp knife until good nerve fibers appear. At that point the section should be completed. This scheme avoids much handling of the nerve. Approximation of the cut ends of the nerve should be obtained by movements of the nearby joints, which will often make up for a gap of 1½ or 2 inches. If this is not sufficient to allow the nerve ends to come together without tension, then freeing of the nerve trunk in both directions for long distances may be employed. In some nerves, length may be gained by transposition. Thus the ulnar may be transposed from the back to the front of the arm. Moderate tension at the point of suture does not seem to preclude good results, but it is better, if possible, to have the ends come together without tension. If none of these measures will serve to approximate the ends, then some form of nerve grafting may be employed. How successful this procedure is I do not yet know. Suture is best done by a series of interrupted stitches through the sheath only, around the periphery. As few of these as will serve to form a good joint should be used. Sutures through the nerve trunk should be avoided if possible. Either fine silk or fine catgut are good materials for the suture.

Various methods of wrapping the suture line in fascia or in Cargile membrane or other substance to prevent constriction of new scar are used. These measures sometimes defeat their own object by causing more scar tissue to form. The best plan seems to be to find a fresh muscle groove in which to bury the suture line. I have yet to see implantation of one nerve into another serve a useful purpose.

In general, the results of nerve suture are extremely encouraging, but their success is dependent on two things, early operation and careful mechanical and electrical after-treatment of the tissues supplied.

CONCLUSION

It has been my desire in this article to give physicians in the United States a summary of the sort of work that will face them all, to a greater or less extent, when our men have gone through some of the actual fighting in the battle front. It is intended to give an idea of how much can be done toward restoration of the war cripples, and of what value reconstructive surgery is. In closing, let me say a word of appreciation of the work that has been done in England toward the rehabilitation of thousands of men, who, before this war, would have been discarded as cripples. Sir Robert Jones has done much to center attention on this reconstructive work, but there is much left to be done. I trust that the Medical Corps of our own Army will be able to take up the good work where he has left it off, and that the application of orthopedic principles, added to those of surgery, will do much to neutralize the effects of the frightful destructive injuries that the war is sure to produce among our men.

TREATMENT OF ECLAMPSIA

J. CLIFTON EDGAR, M.D.
NEW YORK

Convulsive toxemia, except in a small minority of instances, is always preventable. There are even those optimists who state that if certain measures of prevention are carried out, eclamptic convulsions will cease to exist.

Be this as it may, the symptoms of a pregnancy toxemia are readily recognizable. Witness the almost entire absence of convulsive toxemia among the antepartum patients of a maternity hospital and among patients in private practice, who are under conscientious medical observation from early pregnancy, and who faithfully follow the directions of their medical attendant. The exceptional cases that "get by," so to speak, are the fulminant cases of hepatic toxemia, with no edema, little change in the composition or output of the urine, and with convulsions following shortly on the onset of the nausea and vomiting, headache or visual disturbances.

The nausea, vomiting, headache, edema, diminished urinary output, constipation, eye symptoms, nervous symptoms, and high blood pressure, aside from the urinary findings of albumin, casts, blood, indican, acetone, and possibly faulty nitrogen metabolism, are usually, if not always, sufficiently plain of the clinical picture of pregnancy toxemia. Physicians, hospital interns, and trained nurses after very little experience recognize the picture, social workers in the tenements have been known to, and even the much maligned midwife, in spite of her at present all too short period of instruction, soon acquires the knowledge that permits the detection of beginning pregnancy toxemia.

We have all had cases of eclampsia in our practice. When such a calamity occurred, it was because we did not watch our cases of pregnancy as carefully as we should, because the patient did not apply for treatment until the toxemia was well advanced, or because the patient neglected or refused to carry out simple preventive or curative measures — would not report for observation, failed to send specimens of urine for analysis, neglected her bowels, or indulged in alcohol or a high nitrogen diet, or both.

If it be only partially true that the early recognition and treatment of pregnancy toxemia will eliminate convulsive toxemia with its high mortality, then surely the preventive treatment is to be reckoned with and is all important.

PREVENTIVE TREATMENT

For years it has been realized that thousands of pregnant women are practically unobserved, until at or near their date of confinement. For instance, patients of maternity hospitals, midwives and all too often of private practitioners are not even seen until after the onset of labor. In 1917, 141,564 births were reported to the New York Department of Health. Out of this number it is perhaps safe to state that 75,000 women went into labor without any prepartum observation whatever.

Hence a long step forward in the prevention of eclampsia is the attention that in the past few years has been directed to the importance of prenatal care of women, especially of the poorer class, for the purpose of reducing infant and maternal mortality.

One outcome of this agitation is the recent organization of the Maternity Service Association of the City of New York, organized mainly, if not entirely, through the earnest and untiring efforts of Dr. Ralph W. Lobenstein, in conjunction with the New York Department of Health.

One aim, among others, of the nurses of a maternity center is to seek out, among the women of the tenements, those showing signs of pregnancy toxemia, kidney insufficiency if you will, and refer such women to the proper clinic or hospital of the sanitary zone in which they reside.

Most maternity hospitals hold daily, biweekly or triweekly prenatal clinics, with indifferent or even deplorable results by reason of the difficulties and cost of a comprehensive "follow up" system. This at least has been our experience at Bellevue and the Manhattan Maternity. It is not unusual for eclampsia to develop among the patients after registering in the prenatal clinics.

Let us glance for a moment at the working of the first maternity center, established at 219 East Seventy-Ninth Street, in the so-called Zone 7, this being the district to which the Manhattan Maternity is now confining its work. Incidentally it is not too much to state that we are entering on a new era in the prevention of eclampsia. During January, 1918, twenty patients suffering from various prenatal and postpartum conditions were referred by the nurses of the maternity center to the Manhattan Maternity. Nine of these women received into the hospital were instances of pregnancy toxemia. Five were primiparas, four multiparas, the blood pressure ranged from normal to 228 mm.; all had albumin in the urine, four had casts, and one had blood; gastric disturbances were present in all and edema in most; eleven convulsions occurred in one woman, and two in another after admission; seven had labor induced by Champetier de Ribes bags; the two convulsive cases went into labor spontaneously. In only one instance were forceps used. In one twin case version and breech extraction was demanded. In a fetus dead from prolapse of the cord, perforation and extraction were performed. All the nine mothers are alive today.

Of the ten children, there being a twin case, one was lost from prolapse of the cord, one was stillborn at term, probably from toxemia, and one, a 3-pound macerated fetus, was delivered. This patient had experienced seven previous stillbirths. She had a negative Wassermann reaction. One can hardly question but that the saving of all the mothers and the seven babies out of ten was due to the early recognition and treatment of the preeclamptic state.

CURATIVE TREATMENT

Our time-honored principles of the curative treatment of toxemic convulsions, namely, (1) control of the convulsions; (2) elimination of the toxins, and (3) termination of the pregnancy, still hold good, although recent clinical experience has somewhat modified them.

A certain number of eclamptic patients, from 8 to 10 per cent. for a minimum, will die, no matter what treatment is used or not used, and the majority, 80 or 90 per cent., will recover under a conservative treatment, which does not include shock-producing operations or shock-producing drugs.

A one-time advocate of active surgical and medical treatment, and bitterly opposed to morphin in eclampsia, experience of the past five years has radically changed my views and teaching. Like many another obstetrician, I frankly confess to have been won over to the use of morphin. *I stand for a reasonably conservative treatment*, neither an ultraradical, with its incisions of the cervix, accouchment forcé, difficult forceps or version, vaginal or abdominal cesarean operations on the one hand, nor an ultraconservative treatment, with its main reliance on morphin and eliminations, on the other. So long as eclampsia is a mystery, a disease of theories, no one treatment is applicable to all cases.

At the same time, in spite of the claims of many, it is very difficult or impossible to individualize one's cases. All eclamptics have toxemia as the underlying causative factor, whatever the clinical variety, liver, kidney or acidosis. In given instances an ultraconservative treatment might cause more harm than an ultraradical treatment. One would, perhaps, unhesitatingly accept the ultraconservative method were it not for the clinical fact, which, as far as I am aware, has never been disproved, namely, that the shorter the time that elapses between the first convulsion and the emptying of the uterus, the better the prognosis for mother and fetus. This apparent fact I referred to in 1913, and clinical observation since that time has strengthened the belief.

Given a case of convulsive toxemia: While the treatment is still empiric, a modified conservative treatment has given me the best results. Chloroform, nitrous oxid, and even ether, should be avoided if possible. The first has been shown to predispose to or cause hepatic necrosis; the second temporarily increases blood pressure and favors cerebral congestion. Ether is the safest. It should be borne in mind that any vapor anesthesia long continued lessens the patient's chances.

A full dose, half a grain of morphin, is administered hypodermically in place of vapor anesthesia. A catheterized specimen of urine is *now* taken for examination. The stomach is then washed out with a sodium bicarbonate solution, and 2 ounces of magnesium sulphate in solution are placed in the stomach before withdrawal of the stomach tube. Some use castor oil in place of the magnesium sulphate. I sometimes substitute 3 drops of croton oil in sweet oil. Magnesium sulphate seems to act promptly and with very little irritation. A colonic irrigation of several gallons (from 4 to 5) of a 5 per cent. glucose solution is now given. Some use sodium bicarbonate. I never use sodium chlorid solution.

If possible, the patient is placed in a darkened room, and kept as quiet as possible. In a hospital ward screens are placed about the bed. The importance of free ventilation is to be remembered. The morphin is repeated in smaller doses (from 1/6 to 1/4 grain), according to indications, keeping the respirations in the neighborhood of 10 or 12. I do not follow a routine. In patients of marked nervous instability, a full dose of sodium bromid (from 30 to 40 grains) in solution by rectum often assists the morphin in controlling the convulsions. I have entirely abandoned the use of chloral hydrate.

I am still uncertain whether the morphin increases the infant mortality. Possibly it does. Even in high systolic blood pressure (from 175 to 200 mm.) I do not employ phlebotomy as frequently as I formerly did, as I fear the concentration of the toxins and the sudden subsequent fall of blood pressure with even spontaneous labor, as has been observed in the use of veratrum viride.

Multiparas, in the absence of obstructed labor, with their comparatively short period of prospective labor ahead of them, are ideal cases, good risks for the conservative morphin, eliminative, noninterference treatment. Primiparas, on the other hand, with their twenty hours of prospective labor to face and their greater intra-abdominal pressure, are not such good risks. And then unfortunately eclampsia is four times more common in the latter than in the former.

An arrangement of electric lights in a rack is now placed over the patient wrapped in blankets, and a moderate perspiration is kept up for several hours. I find this plan of sweating preferable to the usual hot pack, because the patient is less disturbed by it, there is less danger of chilling of the surface in changing, better control of the degree of sweating is had, and sudden concentration of the toxin is avoided. The danger of oversweating is to be reckoned with. During the sweating, water, if possible, is freely administered.

So much for the control of the convulsions and the eliminative treatment. Aside from the first full dose, and the repeated smaller doses of morphin, most obstetricians are in accord with the foregoing treatment; but whether the termination of the pregnancy or labor shall be spontaneous or artificial has caused endless argument. Eclamptic patients are the worst kind of surgical risks; they are most susceptible to shock—shock of operation, shock from cardiac depressants like veratrum viride, phlebotomy and oversweating.

Opposed to the purely expectant plan regarding delivery stands the clinical fact, already referred to, that the shorter the time that elapses between the first convulsion and the emptying of the uterus, the better the prognosis for mother and child.

The beneficial results obtained from the removal of the fetus and uterine contents is largely, I believe, a matter of pressure relief, not the doing away with the nitrogenous output of the fetus or placenta: relief from pressure on the kidneys and renal vessels, pressure on the intestine, portal circulation and liver. Witness the frequency of eclampsia at or near term, the severity of the attack in hydramnios cases, in twin pregnancy, and on the other hand, the improvement so frequently observed after spontaneous or artificial rupture of the membranes. However, better an expectant attitude, with our main reliance on morphin and eliminatives, than a shock-producing delivery operation.

A one-time enthusiast in the free employment of veratrum viride in eclampsia, I frankly confess to having changed my views. I fear its shock-producing effect, although I still occasionally use small repeated doses in selected cases. Glyceryl trinitrate must be reckoned with to reduce arterial pressure, and for its diuretic action. Chloral hydrate I have abandoned, and I use sodium bromid in its place. The treatment of the overwhelming of the cardiovascular system by the toxin or toxins, with the accompanying collapse and pulmonary edema, is based on general principles, namely, caffein, epinephrin chlorid, cupping, intravenous infusions, oxygen, and even strychnin.

Stroganoff with the morphin treatment and an ultraconservative surgical treatment in 360 cases claims a maternal mortality of 6.6 per cent. and a fetal mortality of 21 per cent. Tweedy of the Dublin Rotunda with morphin and a less conservative surgical treatment, in seventy-four patients had a maternal mortality of 8.11 per cent., and a fetal of 30 per cent. Tweedy delivered by forceps after dilation of the cervix; Stroganoff gave large doses of chloral hydrate by rectum.

Two or even three grains of morphin are given in the first twenty-four hours. Others in smaller series of cases have had similar results. Kosmak with morphin elimination, and phlebotomy with a blood pressure over 175 systolic, in thirty-five cases had a maternal mortality of 8.6 per cent., and a stillbirth mortality of 40 per cent.

Difficult forceps operation, forcible dilation of the cervix, incisions of the cervix, and vaginal cesarean section have no place in the modern treatment of eclampsia at term. A single low forceps operation is always in order. Ether is the only anesthetic to be used for any operation.

The same may be said of hydrostatic bags to induce or shorten the labor, as well as the manual dilation of a soft, already partially dilated cervix, to permit of a medium or low forceps operation. My belief is that in the presence of a disease with such a high fetal mortality from any treatment, perforation of the head and a careful extraction of the body should be justified to shorten the interval between the first convulsion and delivery in certain instances.

Until we know more of the causative factors in eclampsia, abdominal cesarean section will always demand a place in the treatment. I believe the indications for the operation are still limited by reason of the remarkable results that have been obtained from the morphin treatment.

Abdominal cesarean section must be considered in a primipara with a long, undilated cervix, to anticipate the twenty hours of spontaneous labor that she would otherwise pass through. A twenty minute abdominal cesarean section, in our present knowledge of eclampsia, would appear preferable to the shock of a difficult version and extraction in a shoulder presentation, or the shock of a prolonged labor in moderately obstructed labor, whether of pelvic or of fetal origin.

I have yet to convince myself that the intensity of the toxemia is an indication for cesarean section. I look on the operation as a substitute for the more shock-producing operations, and to save certain patients from a twenty hour labor and pressure, especially primiparous patients. With the prospect of a short labor, cesarean section does not appeal to me.

It would appear, however, that abdominal cesarean section at term and vaginal cesarean section in the middle third of gestation have their indication in primiparous patients with undilated cervix, and with the familiar clinical picture of profound toxemia, namely, scanty urine, loaded with albumin and casts and especially blood, by catheterization of the bladder in these patients; frequently convulsions, the coma persisting during the whole period of the intervals; retinal changes and hemorrhage, as shown by the ophthalmoscope; and persistence of the cyanosis of the convulsions into the intervals.

A review of the present and prospective obstetric situation causes a recurrence of the reflection that the very poor and the well-to-do are today receiving the best obstetric care, while those of the so-called middle class are the ones, who, all too often, suffer from indifferent prenatal attention.

28 West Fifty-Sixth Street.

THE RELATION OF BLOOD PRESSURE TO CONVULSIONS*

D. M. ERVIN, M.D.
CINCINNATI

There is some factor at work in the course of a convulsion that brings it on and again stops it. That the convulsion stops is an argument in itself against the belief that a chemical substance reaches such a concentration as directly to produce the convulsion. If there is in the blood a chemical, the concentration of which increases to a point at which it produces a convulsion, does its decrease in concentration or disappearance permit the convulsion to end? From the following observations we may think of the chemical as only producing an edema of the brain. The chemical continues as an increasing factor, and the balance between the intracranial pressure and the blood pressure, the variable.

It is well known that the blood pressure is a function of the intracranial pressure, rising directly with it. Normally the blood pressure is higher than the intracranial pressure. The height of the blood pressure over that of the intracranial, or the difference between the two, is a margin of safety. As these two approximate, as the margin diminishes toward zero or even to a negative quantity (that is, when the blood pressure is less than the intracranial pressure), less blood is sent to the brain in a direct proportion. As the margin remains at a small positive quantity, the brain must undergo some changes; for example, the vasomotor center fags. As a consequence, the blood pressure, which has been maintained as high as possible to counteract the high intracranial pressure, drops. The intracranial pressure now becomes greater than that of the blood, the margin a negative quantity; the pupils dilate, and the convulsion comes on. The sharp, tense contractions of the muscles play a vicarious part by forcing the blood from the periphery and raising that in the brain until the margin is again a positive quantity. With its renewed blood supply the centers take up their work again for the time.

OBSERVATIONS

All measurements were made with the Tycos apparatus.

Observation 1.—A colored man, aged 55, entered while in coma. There was marked edema. The urine was acid (methyl red); it contained albumin, 6 gm. per thousand, and casts of all types in large quantities, but no sugar. The clinical diagnosis was uremia. At the point marked *X* in Chart 1, immediately after the fourth convulsion, 1/100 grain of nitroglycerin was put on the tongue. It will be noticed that the blood pressure did not rise as usual to 190 or 195, but fell with another convulsion. Only four observations are recorded, but ten were taken with similar rising and falling pressure and convulsions.

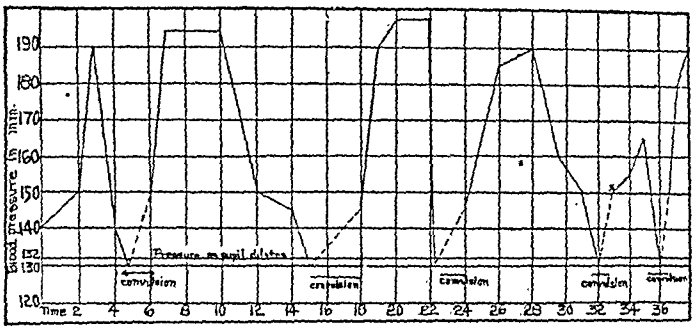

Chart 1.—Blood pressure in Observation 1. In this and the following charts, the ordinate represents the blood pressure in millimeters, and the abscissa, the time in minutes.

TABLE 1.—PROTOCOL OF OBSERVATION 1

			5:39:30	160	Convulsion
5:22	190		5:40	180	
5:23	197	Until after	5:41	190	

Observation 2.—In a pregnant white woman, aged 23, convulsions came on gradually in afternoon and increased in their rate of occurrence and severity. The urine was acid, and contained albumin, 7 gm. per thousand, and casts of all types, but no sugar. Four observations of the eight taken are charted; the remaining four gave the same findings.

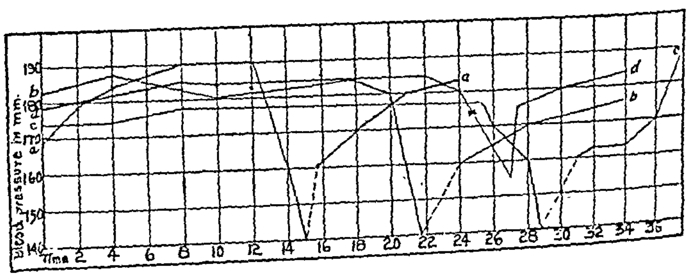

Chart 2.—Blood pressure in Observation 2.

At point *X*, Observation D, Chart 2, 15 drops of epinephrin were given. The blood pressure was already on the way down, but was stopped, and the usual convulsion did not take place.

7:59	130	Convulsion ended
7:60	150	
7:62	155	

Observation 4.—These observations were taken at 2 a. m., when the patient was brought into hospital; the convulsions had started early the morning before. At the beginning the blood pressure very likely rose to 180 or 190, but toward the end the ability to maintain the advantage given by the muscles in convulsions was not possible. In addition, the muscles were fatigued.

SUMMARY AND CONCLUSIONS

Detailed observations on four patients with convulsions show that a convulsion is precipitated in all probability when the blood pressure becomes lower than the intracranial pressure, and that measures taken to raise the peripheral pressure will stop a convulsion, since the blood pressure is a function of the intracranial pressure. It logically follows that measures must be taken to reduce the intracranial pressure in order to accomplish any permanent relief.

A NEW METHOD FOR ESTIMATING TOTAL BLOOD VOLUME IN ANEMIAS

PRELIMINARY REPORT

EDWARD LINDEMAN, M.D.
NEW YORK

The total quantity of blood in the human body is a problem that has baffled men in medical science ever since Harvey's discovery of the circulation of the blood. It is a matter of no small importance in many diseased conditions, and in functional disorders in which no organic disease exists. In recent years, attempts have been made to estimate the quantity of blood; and perhaps a brief review of methods and results will be of interest.

Welcker,[1] in 1854, devised the first method for estimating blood volume. He bled an animal, weighed the quantity of blood obtained, then washed out the blood vessels with water, and estimated the amount of hemoglobin in the washings.

Gréhant,[2] in 1882, took a specimen of blood and calculated the percentage by volume of oxygen by extraction with a gas pump. The animal was made to breathe carbon monoxid gas for a certain time, and the total amount of carbon monoxid absorbed was determined by analysis. A second specimen was next taken, and the percentage of oxygen by volume was again determined. The difference between the percentage by volume of oxygen before and after the administration of the carbon monoxid gas is the percentage by volume of carbon monoxid in the blood, since the latter gas displaces an equal volume of oxygen in the blood.

If the total volume is indicated by V, and the percentage by volume, that is, the number of cubic centimeters of carbon monoxid to each hundred c.c. of blood, is indicated by v, then the total quantity of blood equals:

$$\frac{V}{v} \times 100.$$

By this method, Gréhant established these percentages by volume: for the dog, 7.7; the rabbit, 5; the cat, 5, and the bird 10 per cent. of blood per body weight.

Bischoff,[3] in 1856, applied Welcker's method to two men guillotined, and obtained values of 7.7 and 7.2 per cent., respectively, of body weight.

---

1. Welcker, H.: Bestimmungen der Menge des Körperblutes und der Blutfärbekraft, sowie Bestimmungen von Zahl, Maass, Oberfläche und Volumen des einzelnen Blutkörperchens beim Thier und beim Menschen, Präger Vrtljschr., 1854, 4, 11; Ztschr. f. rat. Med., 1858, 4, 145.

2. Gréhant and Quinquaud: Measure du volume de sang contenu dans l'organisme d'un mammifère vivant, Compt. rend. Acad. d. sc., 1882, 94, 1450.

3. Bischoff, L. A.: Bestimmungen der Blutmenge bei einem Hingerichteten, Ztschr. f. Wissensch. zool., 1856, 7, 331; Abermalige Bestimmung der Blutmenge bei einem Hingerichteten, ibid., 1858, 9, 65.

Gréhant's method was modified by Haldane and Smith[4] and applied to man. They obtained values approximating 5 per cent. of body weight.

Zuntz and also Plesch[5] employed in their determinations the method of Gréhant, as *modified by* Haldane and Smith.

Keith, Rowntree and Geraghty,[6] *in* 1915, injected intravenously a 1.5 per cent. solution of vital red in distilled water. Of this dye, which is disodium disulphonaphthol azotetramethyl triphenal methane, they employed 3 mg. per kilogram. Specimens were drawn before and after the introduction of the dye.

The foregoing methods present serious objections in many cases in which the blood volume is important.

The method of Haldane and Smith has no practical value in anemias, and, furthermore, the estimates by this method are apparently low.

The method of Keith, Rowntree and Geraghty is not free from criticism. They themselves cite three objections to the method:

> 1. There is at times a hemolysis caused by the injection of the dye. This hemolysis makes readings inaccurate, and in hemolytic anemias, hemolysis should be avoided.
>
> 2. When lipemia exists, readings are impossible. In 9 per cent., chilly sensations occurred. In 5 per cent., chills and fever occurred with a rise of temperature to 101.
>
> 3. Dyeing of the skin has occurred.

The antitoxin method of von Behring[7] deserves mention.

Quincke,[8] in 1877, attempted to estimate the blood volume from the change in the blood counts before and after transfusion with the introduction of a known quantity of blood.

In 1914 I used a method similar to Quincke's and encountered many difficulties. The patients were often far away from the laboratory. The delay in the counts made this method difficult, arduous and unreliable. When such work was deputized to assistants and interns, the percentage of error due to the personal equation rendered such calculations often highly inaccurate. I believe our methods of counting blood corpuscles are less accurate than they are credited with being. Blood counts made for the purpose of calculating blood volume should be made immediately before transfusion.

To overcome these difficulties I have devised the following method:

AUTHOR'S METHOD

The patient and the donor are prepared for blood transfusion. Lindeman cannulas are inserted into the veins. These cannulas are of 20 gage, permitting a free flow of blood. When the cannulas are inserted, a slight compression is made on the veins by a tourniquet so that the blood is not taken from a congested limb, and specimens are then taken. Blood transfusion is then immediately performed by the syringe-cannula system[9] as devised by myself without recourse to saline or other foreign material, such as citrate or herudin.

The quantity of each syringeful of blood introduced into the patient is accurately recorded. Three minutes after the completion of the transfusion, the vein of the opposite arm is tapped for a third specimen. These specimens are gathered in calibrated centrifuge tubes, each of which contains 0.2 c.c. of saturated solution of potassium oxalate. The specimens are agitated slightly to produce a thorough mixture of the oxalate with the blood in order to prevent coagulation. They are corked immediately to prevent evaporation. About 6 c.c. of blood are gathered in each tube. These specimens are centrifugalized at a speed of 3,000 revolutions a minute for a period of twenty minutes, when no further reduction in volume of the sediment occurs. The readings are then made from the scale with the aid of a magnifying glass. The percentage by volume of red and white cells, inclusive, is then recorded, correction being made for the potassium oxalate in the tubes.

If x equals the initial volume of blood in the body, and we know the initial cell percentage by volume, the cell percentage by volume of the blood introduced and the quantity of blood introduced, and also the cell percentage by volume of the patient's blood after the transfusion, it is a simple matter, by the accompanying formula, to calculate the volume of blood.

FORMULA

If
x=initial volume
a=R. B. C. vol. % of initial volume
b=volume introduced
c=R. B. C. vol. % of volume introduced
l=Final vol. % R. B. C.
Then:

$$xa + bc = l(x + b)$$
$$xa + bc = lx + lb$$
$$xa - lx = lb - bc$$
$$x(a - l) = lb - bc$$
$$x = \frac{lb - bc}{a - l}$$

The cell percentage by volume of the donor remains remarkably constant throughout the transfusion. In a series of observations I have made I find that the cell volume reduction of donors during the transfusion does not exceed 1 per cent. because of the rapidity of operation and the delay in blood dilution. The values, therefore, by this slight change in cell volume are altered too little to effect any appreciable change in the calculations.

This method, where applicable, as in anemia, is practically free from error introduced by the personal equation, and is accurate unless we assume a difference in the cell percentage by volume of the blood taken from the two arms, after allowing a mixing time interval of three minutes, which is outside the realms of probability.

In making these determinations I have encountered no hemolysis in any of the serums after transfusion as determined by inspection. This is also borne out by the fact that no reactions have been observed in the patients after transfusion. Whenever hemolysis occurs, chills and fever follow transfusion. No chills occurred in any of the cases of blood volume studies. In fact, in my syringe cannula method of blood transfusion[9] I have finally succeeded in eliminating post-transfusion chills. In the last 125 consecutive cases not a single chill has occurred.

The time elapsing for the performance of these transfusions was from ten to fourteen minutes.

The results obtained by means of these estimations have been most gratifying and helpful in the management of the cases.

REPORT OF CASE

History.—Miss K., aged 26, 5 feet 4 inches in height, and weighing 130 pounds, referred to me by Drs. W. A. Downs and Walter Bastedo, had suffered with gastro-intestinal disturbances for years—ever since she could remember. At the age of 16 she began to vomit blood, and had been vomiting blood at weekly intervals ever since, sometimes abundantly, and at other times in small amounts. In 1911, Sir Harold Stiles of Edinburgh performed a gastro-enterostomy without relief. The patient did not know the condition found at operation. She had had blood in the stools frequently, and had a very large hemorrhage, Dec. 26, 1917. Since her last hemorrhage she had been growing increasingly paler and weaker.

Physical Examination.—The patient had a drawn, pinched, ashy look about her face. Her friends said that only six months before she had a fairly good, rosy color. Her pulse volume was small. Her voice sounded very weak. Mentally she was very active and fully conscious, and extremely nervous and irritable. There were pulsations of the veins in the neck. Hemic murmurs were noted all over the precordium. There was no air hunger, but respirations were deeper than usual. The patient was not strong enough to raise herself in bed. She had no appetite. The stools were black and tarry. The patient suffered from constipation.

The patient, a writer by occupation, told me that her brain was usually more active, and that her ideas flowed more rapidly, after the hemorrhages. There had been no bleeding other than from the rectum and the stomach. There was no purpura or other evidence of a hemorrhagic diathesis, and no evidence of primary blood disease. The platelet count was normal. The physical examination otherwise was negative.

Transfusion and Operation.—Before the patient was taken to the operating room, she said it was useless; she was discouraged and felt that she could not live. Before transfusion, the red blood cells were 1,300,000, and the hemoglobin, 20 per cent. The blood clot was well formed, large and firm, and the coagulation time, six minutes.

Dr. Downes operated on the patient immediately after I had performed the transfusion. No evidence of a bleeding ulcer could be found. She had a velvety, boggy, congested mucosa with somewhat dilated veins, but no evidence of any bleeding point. Dr. Bastedo thought the ulcer might be of the rare variety in which the base is well hidden and buried deep in the mucosa, and not visible in spite of careful but limited exploration.

The old gastro-enterostomy did not allow a free passage for material, so that a new anastomosis was made between the first portion of the jejunum and the duodenum. There has been no recurrence of bleeding since the operation.

The amount of blood transfused was 1,500 c.c., and the time required was fourteen minutes.

The amount of blood withdrawn for blood tests before transfusion was 70 c.c.

The cell volume before transfusion was 13.7 per cent.

The cell volume after transfusion was 25.5 per cent.

The cell volume of the donor was 40 per cent.

Application of the formula reveals that the patient possessed a blood volume equal to:

$$\frac{40 \times 1{,}500 - 25.5 \times 1{,}500}{25.5 - 13.7} = 1{,}843 \text{ c.c.} + 70 \text{ c.c.} = 1{,}913 \text{ c.c.}$$

COMMENT

The patient presented a clinical picture of chronic rather than acute bleeding, because of her ability to stand her grave anemia in the presence of a small blood volume.

A very singular happening during the transfusion was her failure to note any improvement in her condition until she had received about 1,000 c.c. of blood. From that moment she noticed improvement symptomatically, and when she had received 1,500 c.c. of blood, she felt like a new person. More could have been obtained from the donor, and the patient could have accepted even more; but it was felt that she had received enough to convert her from an extremely poor surgical risk to a comparatively good one. She accepted the anesthetic very well. The operative period was one hour. On the day following her operation she expressed a desire for food. Her convalescence has been one of steady improvement, with no recurrence of bleeding. There was no chill or reaction after transfusion. She now eats many things she could not eat for many years.

This patient had a blood volume of only 40 per cent. of what she normally should have, and only 25 per cent. of her normal richness. This would give her a combined impoverishment of about 90 per cent. of her full blood strength and normal volume.

This paper is to serve merely as a preliminary report. Further estimations of blood volume in various conditions will be published in later papers.

TUBERCULOSIS AND SYPHILIS

EDWARD von ADELUNG, M.D.
OAKLAND, CALIF.

For the purpose of impressing the necessity of applying the Wassermann test to tuberculous patients, and thus avoiding a considerable percentage of common error, a tabulation of the cases seen in the Alameda County Tuberculosis Clinic during the past four years is here presented.

The data were gathered in the course of regular examinations of patients in the Clinic of the Alameda County Society for the Study and Prevention of Tuberculosis—a society financed by annual appropriations from the treasuries of Alameda County and Oakland City, supplemented by contributions from private purses. In this work, I have been greatly assisted by Dr. Philip F. Abbott and Dr. V. O. Saphro. The Wassermann tests were made at the California State Hygienic Laboratory, Berkeley, Calif.

POSITIVE WASSERMANN TESTS IN TUBERCULOUS PATIENTS

Year	Tuberculous Patients No.	Positive Wassermann Tests No.	Positive Wassermann Tests Per Cent.
1914	34	8	23.5
1915	52	4	7.6
1916	61	2	3.2
1917	48	3	6.2
Totals	195	17	8.7

In 1914, of thirty-four cases of tuberculosis confirmed by the finding of tubercle bacilli in the sputum, eight yielded positive Wassermann tests. This means that 23.5 per cent. of syphilis was found during 1914 in laboratory-positive tuberculosis. Of these eight cases of double infection, 78 per cent. of the patients were female and 22 per cent. male.

In 1915, of fifty-two cases of positive-sputum tuberculous cases, four, or 7.6 per cent., yielded positive Wassermann tests. Of these four patients, 25 per cent. were female and 75 per cent. male.

In 1916, of sixty-one cases of pulmonary tuberculosis, two, or 3.2 per cent., yielded positive Wassermann tests. Both of the patients were women.

In 1917, of forty-eight positive-sputum cases of tuberculosis, three, or 6.2 per cent., yielded positive Wassermann tests.

Summing them up for four years, it is seen that of 195 cases of pulmonary tuberculosis confirmed by finding the bacilli, seventeen, or 8.7 per cent., yielded a positive Wassermann test. This represents what would be overlooked by the average practitioner, when treating open cases of tuberculosis of the lungs without making the Wassermann test.

ANATOMIC DEFECTS IN THE NEW-BORN DEMANDING SURGICAL OPERATION

REPORT OF A CASE OF UTERINE TUMOR

E. M. PRINCE, M.D.
BIRMINGHAM, ALA.

After a few years of surgical practice, one is impressed with the number of new-born children who have one or more anatomic defects amenable to surgical treatment, which, if not dealt with surgically, will mean the death of the infant.

During my first few years of surgical practice, when confronted with these little sufferers, I was inclined to do nothing, feeling that an infant of only a few hours, or a few days, was sure to lose its life if any major operation was attempted. During later years, however, and after operating on some of these children, I am thoroughly convinced that they are at least as able to withstand the shock of operation as their older brothers and sisters. Of course, much depends on the anesthetic and the anesthetist, when an operation is undertaken. I think that, in the very young, ether is decidedly the anesthetic of choice. Gas-oxygen is far preferable for children of more advanced years, but the extremely young are more prone to die from respiratory failure, and this is the great danger in operations on infants. It is held by some physicians that the new-born may be operated on without any anesthetic whatsoever, as the nervous system at this early age is as yet undeveloped, and they are not capable of feeling pain. I do not believe this, as I have seen every manifestation that the little patient is suffering great pain when permitted to come out from under the anesthetic while the operation is in progress. I have circumcised infants without an anesthetic, and I think any one who observes them during this little operation will be convinced that they suffer. I think an operation performed on these little subjects should be done with dispatch, with the operator taking all the time necessary to do good surgery, but wasting no unnecessary time. Before he starts the operation, he should decide just what he is going to do, and do it with care and with as few movements as possible.

When he has relieved the congenital defects and sees the little patient begin to gain the health and vigor of babyhood, he cannot help thinking he has done something worth while, for he has brought health to a child and joy to the mother.

think the case that I report of unusual interest, as tient must be the youngest on record to be on for uterine tumor.

REPORT OF CASE

A baby girl, aged 11 hours, sent me by Dr. E. C. Clayton, was a fine-looking baby except that she had a very large hernia. It seemed as if the entire intestine was in this hernia. The intestine was covered only by the peritoneum. One could look into the hernia sac and see the intestine almost as well as if it had been in a glass case. There was a decided lack of development of the left rectus muscle, and under the mass of intestine a large tumor could be felt. This I took for a hydronephrotic kidney.

Under ether anesthesia, the hernial sac was opened. It was found to contain the large intestine and all of the small intestine, the end of the duodenum being pulled down into the sac.

The tumor felt under the hernia proved to be a cystic tumor of the uterus. The uterus was enlarged to the extent that it filled the greater part of the abdominal cavity. The right tube and ovary were missing. A blind tube led from the uterine cornu out into the abdominal cavity for about an inch. An incision was made into this organ, and a large quantity of mucopurulent looking material was evacuated. The uterus then contracted to the size of a large marble, leaving room for replacing the intestine.

An examination of the endometrium through the incision showed it to be normal. The incision in the uterus was then closed, the abdomen was closed, and the child made an uninterrupted recovery.

Fearing the uterus would again become distended with the same fluid after I had closed the abdomen, I pulled the cervix down into view through the vagina. Forceps were inserted through the cervical canal into the organ in order to promote drainage.

DAKIN'S DICHLORAMIN-T SOLUTION FOR OCULAR INFECTIONS

A. S. GREEN, M.D.
AND
L. D. GREEN, M.D.
SAN FRANCISCO

Until recently the search for an antiseptic that would influence the flora of the conjunctiva without at the same time injuring its epithelium seemed almost hopeless. It is true that many so-called antiseptics are often used with excellent results in treating infections of the cornea and the conjunctiva, but with few of them is the benefit derived due to anything but the mechanical cleansing, the possible exceptions being zinc sulphate for infections with the Morax-Axenfeld bacillus, and ethylhydrocuprein, in pneumococcus infections. This conclusion must inevitably be reached by all who have given the subject of ocular antisepsis careful study.

When the wonderful results of the Carrel-Dakin treatment were first reported from the seat of war regarding its remarkable efficacy in preventing and cleaning up the infections of wounds, it occurred to us that the method might be modified in treating infections of the eyes. Here was an antiseptic solution that was destructive to bacteria, but not to animal tissue — just the very thing ophthalmologists had been endeavoring so long to find. Therefore a 1 per cent. watery solution was used in a number of cases of conjunctivitis, 2 drops being instilled every two or three hours, but it was finally abandoned as it was found that the results were in no way superior to those obtained by the solutions ordinarily used in conjunctival infections. Even the weak solutions used for the test were found to be much more irritating than the ordinary remedies. Accordingly, the test was dropped. Several months later, when Dakin published his article on the improvement in the method by using an oily solution known as dichloramin-T, the matter was again taken up and tried out in about two dozen cases with exceptionally satisfactory results, case histories of four being given below as examples.

METHOD OF APPLICATION

Although the use of from 10 to 15 per cent. solutions is recommended by Dakin in general surgery, we found that the best results were obtained by a 0.5 per cent. solution, instilled every hour, at least 3 or 4 drops being used each time. While considerable smarting is caused, this lasts only a moment or two, and is easily borne, even by children.

REPORT OF CASES

Case 1.—T. L., a boy, aged 12, suffering from trachoma of several years' duration, had been given the usual treatment for trachoma, including rolling, grattage, carbon dioxid snow, and copper sulphate, without permanent benefit, for in spite of all the treatment an acute exacerbation would occur from every three to six weeks. His vision was greatly reduced, owing to pannus and corneal opacities, and at no time was he entirely free from a conjunctival discharge. Finally the 0.5 per cent. dichloramin-T solution was given a trial by instillation every hour. On the sixth day there was no discharge, and the lids were not agglutinated in the morning. After three weeks of the treatment the boy was dismissed, and up to the present time, six months later, no recurrence has taken place.

Case 2.—E. R., a girl, aged 5, had been coming to our service at the San Francisco Polyclinic for several months on account of phlyctenular conjunctivitis. The results of the usual methods of treatment fluctuated, and finally she presented herself with an acute infection superimposed in one eye. It was swollen shut, and there was a purulent discharge due to an unidentified diplococcus. She was immediately placed in hospital and the 0.5 per cent. dichloramin-T solution instilled every hour for the first twenty-four hours, at the end of which time the swelling was greatly reduced. The drops were continued every hour the following day, and every two hours that night. At the end of forty-eight hours the child could open the eye, and very little discharge was present. The treatment was then kept up by instillation of the drops every two hours during the day, but none during the night. After the fourth day the child was dismissed from the hospital, no further treatment being required.

Case 3.—A Japanese child, aged 4 years, presented the left eye so swollen shut that the cornea could not be seen even by the use of a lid elevator; the skin at the external canthus was badly excoriated, the condition having existed four days. No smear was obtained. The child was placed in hospital and the use of the 0.5 per cent. dichloramin-T solution begun, instillations being made every hour that day and night. The following day the swelling had receded so that the intact cornea could be seen, and at the end of forty-eight hours the eye was open. In one week from the time it was brought to the office the child was dismissed and taken to its home in the country.

Case 4.—F. B., a boy, aged 3, when first seen had the right eye infected, the lids red and swollen shut, and yellow pus pouring out on the cheek—a typical textbook picture of gonorrheal ophthalmia. Smears revealed numerous gram-negative, intracellular diplococci. The child was placed in hospital and treated with the 0.5 per cent. dichloramin-T solution every two hours and with iced compresses that day and night. The following morning; twelve hours after, there was little, if any, improvement. One drop of 1 per cent. solution of silver nitrate was then instilled, followed by several drops of the dichloramin-T solution every hour, day and night, until at the end of thirty-six hours the swelling had gone down so that the eye was open and only a very slight discharge was present. On the third day a smear from the conjunctiva was negative for all bacteria, and the child was dismissed on the fifth day with only a very little conjunctival redness remaining.

CONCLUSIONS

Dichloramin-T in solutions of from 0.5 to 1 per cent. can be freely used as a conjunctival antiseptic without danger to the tissues. It may possibly be used in stronger solutions, but this has not been found necessary in our experience, although further trial is advocated to determine the matter. The oil solution is preferable to the aqueous, as it is less irritating and will remain longer in contact with the epithelium. Instillations should be made at frequent intervals, once every hour having been found the most satisfactory.

210 Post Street.

INCOMPLETE OUTWARD DISLOCATION OF THE KNEE

RUSSELL S. FERGUSON, A.B.
NEW YORK

Dislocations of the knee comprise only about 1 per cent. of all dislocations.[1] Of these, dislocations outward are exceeded in rarity only by inward dislocations and the dislocations by rotation. Stimson[2] was able to collect only 114 instances of traumatic dislocation of the knee. The dislocations were: forward, 52; backward, 34; outward, 21; inward, 4, and by rotation, 3.

Dislocation of the knee outward occurs in about 0.2 per cent. of all cases of dislocation. The condition is of interest, therefore, because of its infrequency. The case here reported is also of especial interest because its etiology differs somewhat from cases previously described and because the method of reduction used was somewhat at variance with previously described textbook methods. I have experimented on the cadaver with the method used to reduce the case under consideration, and it appeared to be the most efficient from the standpoint of conservation of the untorn portions of the joint capsule and of the ligaments, and indeed the only method by which reduction can be satisfactorily effected.

REPORT OF CASE

J. H., a German, aged 31, with a negative medical and surgical history, was admitted, Nov. 10, 1917, about 1 a. m., to the service of Dr. C. J. Pflug, St. Mary's Hospital, Jamaica, L. I.

About thirty-five minutes before admission, while the patient was crossing a dark road, he was struck from the right side by an oncoming automobile. The bumper of the car hit the patient on the lateral aspect of the right thigh just above the knee joint while the foot was relatively fixed on the roadway.

On admission the patient complained of slight lacerations about the face and of severe pain in the region of the right knee. The right leg was held in extension and the foot and the leg were rotated outward to about 20 degrees. On removal of the clothing overlying the injured joint, the lower leg was found to be abducted from the knee about 10 degrees from a straight line, rotated outward about 20 degrees, and in complete extension. The internal condyle of the femur was seen to project under the skin on the internal aspect of the knee. The patella occupied a vertical position on the lateral aspect of the external condyle. The external tuberosity of the tibia was displaced outward and backward. The internal tuberosity was occupying a position in line with the external condyle of the femur, and was displaced slightly in a forward direction. On palpation, the entire internal condyle and the intercondylar groove of the femur could be felt. The patella was absent from its normal position, and could be felt in a vertical plane on the lateral aspect of the external condyle of the femur. The entire external articular surface of the tibia could be palpated, even to the spine separating the two articular surfaces on the head of the tibia. The articular surface of the external condyle of the femur and of the internal articular surface of the tibia exactly coincided. The patient was unable to carry out any voluntary motion of the leg. Passive motion and even light palpation caused exquisite pain.

---

[1] Stimson, L. A.: Fractures and Dislocations, Ed. 7, Philadelphia, Lea and Febiger, 1912, pp. 850-851.

[2] Stimson, L. A.: Fractures and Dislocations, Ed. 7, p. 851.

Chloroform was administered, and the reduction of the dislocation accomplished in the following manner: The leg was completely flexed at the knee and at the hip. The left hand of the operator was held behind the head of the tibia with the thumb on the external edge of the patella. The right hand grasped the leg at the ankle. After flexing, the lower leg was internally rotated, traction was made on the head of the tibia, and the leg was extended. After extension, the patella was easily slipped back to its normal position. No difficulty was encountered during this manipulation. A light splint was applied to keep the leg in extension and to prevent abduction. At the end of four days a light plaster bandage was applied to the knee in order to immobilize the joint. After one week's time the plaster bandage was split into anterior and posterior splints, and the knee massaged three times a day. Six weeks after injury, the patient was back at his accustomed duties, the function of the joint being perfect. It is to be regretted that the patient entered the hospital at a time of day when it was impossible to obtain a roentgenogram of the deformity. The condition of the patient was such that immediate reduction was demanded for the relief of pain; otherwise reduction might have been deferred and a picture taken the next morning. A roentgenogram taken the day following reduction showed no fractures or other injuries to the bones.

ETIOLOGY

The usual textbook cause of incomplete outward dislocations of the knee, according to most writers,[3] is abduction of the leg plus outward rotation; or is most commonly due to indirect violence, as in a fall on the abducted foot, and more rarely to a blow received on the lateral aspect of the external condyle of the femur. Cases have resulted from fixation of the thigh, combined with a weight falling on the inside of the lower leg.[4]

In the present case the etiology was probably as follows: As previously stated, the patient was struck directly from the right side by an automobile traveling at a high rate of speed. To the front of the car a broad steel bumper was attached, the lower edge of it corresponding approximately to the lower end of the femur of the patient. Hence, the force acted directly on the lateral aspect of the external condyle of the femur while the leg was in complete extension.

Since the foot was relatively fixed on the ground, the force could act only in the direction of abduction of the leg without rotation. In producing the dislocation on the cadaver by direct abduction without using any rotary force, I found that a similar degree of rotation existed at the end of the traumatism as was seen in the foregoing case. Hence it is probable that the degree of rotation observed in the hospital case was not the result of a rotary type of violence, but due to the resistance of certain joint structures, as is later explained.

REPRODUCTION OF THE INJURY IN THE CADAVER

Knowing the etiology of the present case, I sought to reproduce the injury in the cadaver in order to determine, first, what the pathologic condition was, and secondly, what the method of reduction should be. A well developed cadaver was selected, and only the head, trunk and pelvis were allowed to rest on the table. The leg was held free of the table and fully extended. A small block of wood about 3 inches wide was held on the external condyle of the femur and struck heavily with a large mallet. At the same time the leg was forcibly abducted from the knee. The first attempt only partially produced the degree of injury sought, but on repetition of the force a little more strenuously, the dislocation was effectively produced. The experiment was repeated on three different cadavers. The degree of dislocation was made to correspond with that found in the foregoing case. Examination of the three joints disclosed the fact that the external condyle of the femur and the intercondylar groove could be palpated. The patella invariably lay on the lateral aspect of the external condyle of the femur at right angles to its former plane. The surfaces of the external articular facet of the tibia and the spine which separates the two articular surfaces could be palpated laterally and slightly posteriorly to the external condyle of the femur. In other words, the external condyle of the femur occupied the medial articular facet of the tibia instead of its own lateral articular facet. The injury in the cadaver differed from that in the aforementioned case in that the degree of abduction of the lower leg was about 10 degrees more than that observed in the hospital case. The degree of rotation was practically the same. The rotation outward of the lower leg when the dislocation is produced only by abduction, is to be explained by the action of the posterior crucial ligament, which is untorn in the production of the injury, and tends to limit outward displacement of the tibia by drawing the external tuberosity of the tibia backward.

PATHOLOGY

On dissection of the dislocated joints, the internal lateral ligament, the fascial expansion of the vastus internus, and the internal portion of the joint capsule were found to be torn along a line extending from the lower pole of the patella to the posterior border of the internal condyle of the femur. From the lower pole of the patella the tear extended downward along the internal edge of the ligamentum patellae almost to the tibial tubercle. The anterior crucial ligament was ruptured in each case within one-half inch of its attachment to the femur. The posterior crucial ligament was not torn but was put on the stretch. The attachments of the hamstring muscles and the posterior muscles of the lower leg were not torn. The semilunar cartilages of the knee were undisturbed. The ligaments and the joint capsule on the external and posterior aspects of the knee were uninjured.

METHODS OF REDUCTION

The usual method of reduction[5] described in textbooks is by traction on the lower leg combined with coaptive pressure at the joint, with the leg in extension. The method will usually suffice in cases in which the degree of dislocation does not absolutely displace the condyles from all contact with their respective articular surfaces on the tibia; in other words, if the spine between the two surfaces on the head of the tibia does not pass over the crest of the external condyle, such a method will usually be effective. When the displacement is as great as indicated in this case and in the dislocation produced on the cadaver, however, such a method not only fails in its purpose, but may also result in further damage to the ligamentous structures of the joint. Reduction could be obtained by this method in the cadaver, that is, by traction and coaptive pressure; but the rent in the internal ligaments and the joint capsule was enlarged to a considerable degree, and the posterior crucial ligament was further stretched to such an extent that rupture began at its insertion into the femur.

[5] Cotton, F. J.: [illegible] and Joint Fractures, New York, Rebman Company, 1910, [illegible]ellogg: Fractures and Dislocations, p. 804. Helfer[illegible] and Dislocations, Ed. 5, pp. 287-288. Stimson, L. A.: Fractures and Dislocations, Ed. 7, p. 860.

The method of reduction used in the hospital case and repeated on the cadaver was as follows: The leg was flexed at the hip and knee, which action resulted in decreasing the stress on the posterior crucial ligament and on the untorn portions of the ligaments, comprising the external capsule of the joint, the insertions of the hamstring muscles, the quadriceps, and the gastrocnemius and soleus muscles. Then, on inward rotation of the leg, the lateral displacement was corrected. When reduction was attempted by the method just described, it was found that it resulted in a further decrease in tension on the untorn joint ligaments. When the leg was extended and traction exerted behind the head of the tibia, the deformity was entirely corrected and the leg brought into the normal extended position. The patella was then easily slipped back into place.

It will be seen, therefore, that the method of choice in reducing such a dislocation should be one that will not only correct the displacement, but also conserve to the greatest extent all the ligaments and muscular attachments that have not been damaged in the production of the injury. With the displacement as great as here represented, traction with coaptive pressure at the joint does not result in such a conservation, but puts all the untorn ligaments further on the stretch, and will even cause further damage to them.

In a case reported by Jessup,[6] the degree of dislocation was practically identical with that observed in the present case. His method of reduction was by flexion at the hip and knee, combined with inward rotation and followed by extension. His paper, however, contains no comment on the pathology of the condition, or why such a method of reduction was used. The same patient was reported three years later by Bull[7] as having a functionally useful knee. He also made no comment on the pathology, but described the method of reduction. In Jessup's case the dislocation was produced by a heavy weight falling on the inside of the leg while the thigh was relatively fixed.

Speed,[8] quoting Hardoun's experiments on the cadaver states that the vastus internus may be ruptured, as also the crucial ligaments. He (Hardoun) demonstrated that outward dislocation of the knee, complete or incomplete, is impossible without rupture of the anterior crucial ligament. The patella may be displaced laterally and resist attempts at reduction.

CONCLUSIONS

1. Incomplete traumatic dislocation of the knee outward may be produced by abduction at the knee without rotation of the lower leg. Such force produces an oblique tear in the internal lateral ligaments and joint capsule, extending from the posterior border of the internal condyle of the femur to the lower pole of the patella, with rupture of the anterior crucial ligament.

2. The outward rotation of the leg seen in the experiments on the cadaver, when the dislocating force was pure abduction, appears to result from the action of the untorn posterior crucial ligament. This ligament limits outward displacement of the tibia by causing outward rotation of the leg and slight backward displacement of the external articular surface of the tibia.

3. To conserve the posterior crucial ligament and all untorn portions of the joint capsule, ligaments and muscular insertions, the mechanism of reduction should be by flexion of the hip and knee, combined with the necessary amount of inward rotation. This manipulation may then be followed with safety by full extension, in which position the leg should be immobilized.

VEGETABLE POWDER AS A LARVICIDE IN THE FIGHT AGAINST MOSQUITOES

A PRELIMINARY NOTE

JAMES K. THIBAULT, JR. (WASHINGTON, D. C.)
Bureau of Entomology United States Department of Agriculture
SCOTT, ARK.

With the view to finding some larvicide cheaper than crude oil and just as effective, and at the same time available for use in certain places that can be neither oiled nor drained, such as water gardens, outdoor fish pools, rice fields and the like, I have experimented with many substances during the past few years. I have found not the perfect larvicide I sought, but one that meets at least a few of the requirements of perfection, and that I consider well worth a trial by those engaged in the work of exterminating mosquitoes. While not a substitute of oil under all conditions, it is certainly much cheaper than oil, as easy of application and, in most cases, as effective as oil, and it can be used in places where oil would not serve the purpose.

The larvicide in question consists of various vegetable powders, including the familiar pyrethrum or insect powder of the stores. In fact, all my earlier work was done with the pyrethrum powder, which gave excellent results. But it was so expensive that, had it been generally used and recommended for this work, the cost would have become prohibitive within a short time. So I determined to find some similar powder possessing the good qualities of pyrethrum, and at the same time being available to every one, and not subject to the speculative manipulations of the market.

As the larvicidal action of pyrethrum powder is purely mechanical, I considered it possible to produce a powder from the common weeds of the neighborhood that would be just as effective, and, indeed, I have found this to be the case. The weeds and grasses of nearly every species in the neighborhood, when dried and reduced to powder of the proper fineness, gave very good results, and it is not at all necessary to select any particular species in order to produce an effective powder.

A good powder should spread quickly and evenly over the surface of water even if thrown on by the handful, pushing the resulting film to all parts of the surface to be treated.

It is, however, much more potent when applied in the form of a spray over the entire area of the larger pools. The covering capacity should be from 3,500 to more than 4,000 square feet per pound of powder.

Perhaps the greatest disadvantage in the use of the powder is its short period of effectiveness—probably only a few minutes—but it is so deadly that, once the larvae come in contact with it, they die in a few minutes, even when immediately removed to another receptacle. The powder loses its effectiveness as soon as it is thoroughly wet.

I have found it very effective for killing such well known species as *Anopheles quadrimaculatus, Culex quinquefasciatus, Culex abominator, Aedes cocliumbiae* and *Psorophora cyanescens.* Of these the species with short, thick air tubes such as *Anopheles, Aedes* and *Psorophora* are easily killed, while the species of *Culex* with very long, slender tubes are more resistant, *Culex abominator* being the most resistant species I have had to deal with.

These studies have been made in connection with the work of this bureau on the relation of mosquitoes and malaria to agriculture, under the general supervision of Dr. W. D. Hunter, with Mr. D. L. VanDine in charge of the field work.

PROGRESSIVE MUSCULAR DYSTROPHY *

FRANCIS H. McCRUDDEN, M.D.
BOSTON

The tendency to enlarge on the functional rather than on the structural aspect of the so-called chronic and incurable diseases, and the tendency to consider them less as anatomic, and more as physiologic problems, as a result of the rapid advance of chemical physiology, has resulted in an auspicious change in point of view regarding the nature of disease, the purpose of diagnosis, and the object of treatment. From the new point of view, a diseased organ is one that is functionally unequal to its tasks. Determination of the structural nature and extent of organic defect is, accordingly, only partial, qualitative, anatomic diagnosis, which must be completed by quantitative, physiologic diagnosis, that is to say, measurement of functional capacity. Guided by such measurements, the therapeutist diminishes burdens and augments working powers in an endeavor to balance tasks and capacities.

The most striking feature of this physiologic concept of disease is its usefulness. With functional integrity as our goal, unattainable structural integrity is no longer a therapeutic "no thoroughfare."[1] As a concrete example, let us consider progressive muscular dystrophy.[2]

In progressive muscular dystrophy, we find low blood sugar, and, following treatment which increases the blood sugar, an improvement in muscular strength.[3]

Blood sugar — glucose — is the source of energy for muscular contraction. Active muscle rapidly uses up glucose. As the supply becomes exhausted, muscular strength diminishes and can be restored only by glucose. Agencies such as Addison's disease, diphtheria toxin, and phosphorus and hydrazin poisoning, which reduce the blood sugar, cause profound myasthenia, the severity of which is proportional to the fall in blood sugar. Hypoglycemia, then, sufficiently accounts for the myosthenia, the most striking symptom of progressive muscular dystrophy.

As the glucose of the blood is used up by the muscles, the loss is rapidly and quantitatively made good from the store of glycogen in the liver, the blood sugar being thereby maintained at a fixed level. Hypoglycemia can result only from a failure of replenishment to keep pace with the needs, that is, from a loss of balance between supply and demand.[4] Greater needs, such as increased utilization of sugar, or loss through the kidneys, can be ruled out in progressive muscular dystrophy. There is no rise in heat formation such as would accompany increased sugar catabolism, and the urine is free from sugar. A rapid fall in blood sugar during the first twenty-four hours of starvation — in health, the normal blood sugar level is maintained during starvation — testifies that in progressive muscular dystrophy, as in all forms of experimental hypoglycemia, there is a decreased rate of replenishment resulting from a diminished reserve of glycogen.

The diminished glycogen reserve in experimental hypoglycemia results from impaired glycogen formation. The carbohydrate ingested is not converted into glycogen, but remains a long time in the blood, after which, judging from the amount of "fatty degeneration" in these cases, and from the increased respiratory quotient, and the lipemia, it is probably changed to fat. This supposition is in accord with the well known antagonism between fat storage and glycogen storage. The deposition of fat in the muscles[5] points to a similar impairment of glycogenesis in progressive muscular dystrophy.

Impaired glycogenesis may result from damage either to the liver, the organ in which glycogenesis takes place, or to the suprarenals,[6] the organs that control the process. If the fault is with the suprarenals, administration of epinephrin restores normal glycogenesis. If the fault is with the liver, epinephrin has no effect. A prompt and marked rise in blood sugar following the administration of epinephrin in progressive muscular dystrophy testifies to the efficiency of the liver in this disease and points to a deficiency in epinephrin.[6]

SUMMARY

The myasthenia of progressive muscular dystrophy is due to hypoglycemia, and the hypoglycemia and fat deposition to impaired glycogenesis, the carbohydrate of the food being probably changed largely to fat instead of to glycogen. The impaired glycogenesis is due to suprarenal or other endocrine disease.

THE IMMEDIATE OPERATION FOR PERINEAL LACERATIONS

HENRY A. BERNSTEIN, M.D.
Visiting Obstetrician, and Associate Gynecologist, Beth David Hospital; Instructor in Gynecology, New York Polyclinic Medical School and Hospital
NEW YORK

The literature embracing the study of the repair of the lacerated perineum is so extensive that an apology appears necessary for the introduction of a new discussion on such a time-worn subject; and yet, in spite of the attempts at operation immediately following the conclusion of labor, the great number of women who suffer from unrepaired tears bear evidence to the fact that the last word has not been said on the immediate repair of the perineum.

Investigation into this condition, in a service comprising a large number of obstetric cases, convinced me that fully 75 per cent. of those who have undergone the immediate suturing at the vaginal orifice are in need of a secondary operation. In view of the fact that much more than 50 per cent. of all primiparas are lacerated at the time of their confinement, it is safe to say that something is wrong with the technic generally employed. Surely no harm can result from a further study of the causes of such a deplorable state of affairs, or an effort to find a remedy for its correction. An unhealed or improperly repaired laceration of any part of the birth canal is always a reflection on the ability of the obstetrician, no matter what the cause.

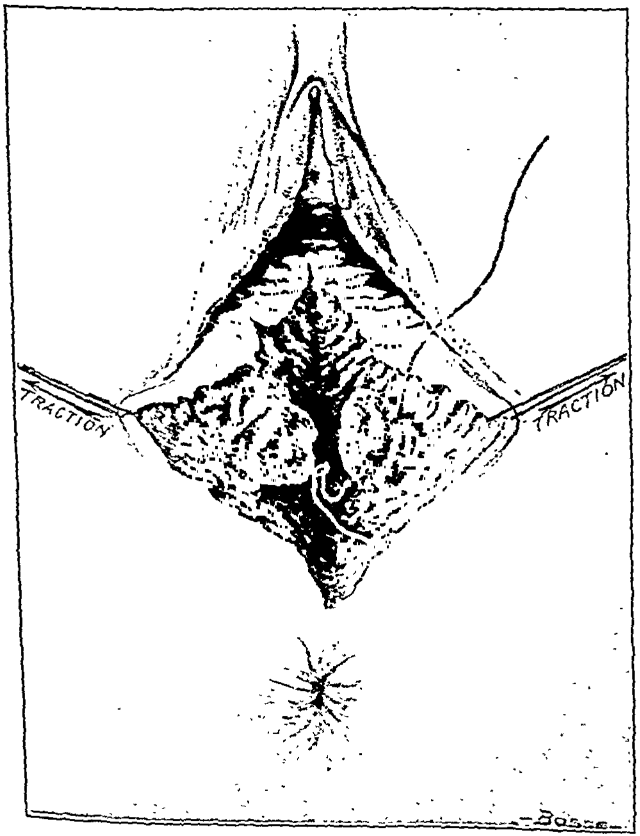

Fig. 1.—Edges of wound held apart by traction sutures, and sutures inserted into torn muscles.

Dissection of the perineum will show that all muscles that are inserted into the central point of this organ arise directly or indirectly from the pubes, the ischium, the sacrum or the coccyx, so that when rupture of the perineum occurs, contractions take place in all directions away from the point of insertion, and distortion of the parts is in direct ratio to the extent and various irregularities of the tears. An intact perineum regulates the contractions of the individual muscles attached to it, and controls and equalizes the tension that these muscles may exert on neighboring organs, such as the anus, the rectum, the bladder, the vagina and the uterus. Even the diaphragm may be acted on under certain conditions.

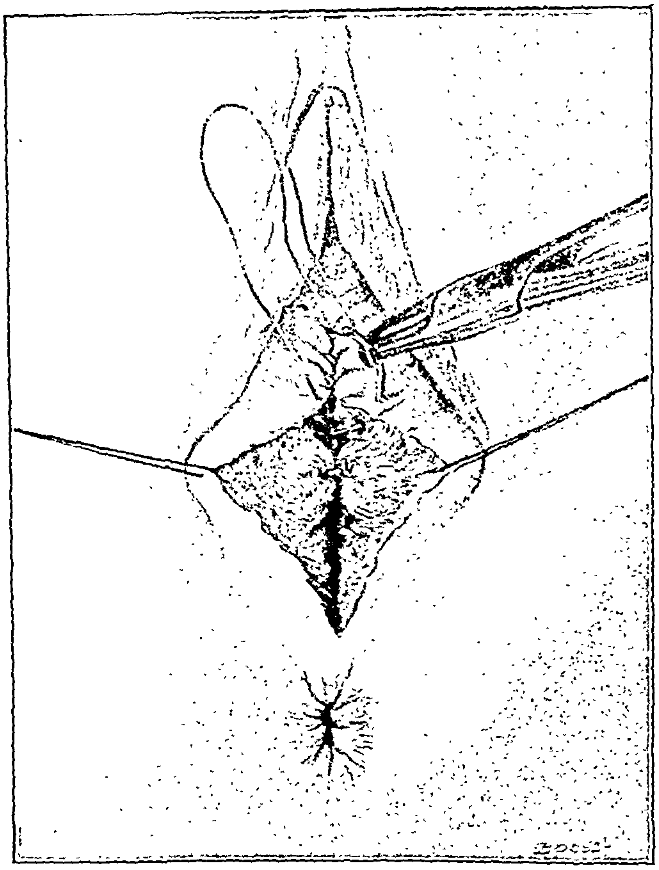

Fig. 2.—Torn ends of muscles joined, and laceration in vaginal mucous membrane partly sutured.

Immediately following labor there always is present some paresis of the perineal muscles, as a result of pressure; and where lacerations have occurred, gaping of the parts begins as soon as the muscles have regained their tone. The gaping accounts for the fact that no lacerated perineum unaided and of its own accord ever can be restored to its original intact condition; and unless the tissues are properly approximated, the distortion is increased rather than diminished.

A review of the literature on this subject reveals that very few authors advise any exact operative procedure; nearly all consider that a few sutures more or less deeply placed from the outer side, so as to include as much as possible of the torn tissues, are sufficient for the purpose. This practice cannot yield a satisfactory result. The torn ends of muscles may be overlapped and are more often not caught up at all, thus leaving a space beneath the surface due to muscular contraction and deficiency, which weakens the nat[illegible]l support and encourages prolapse of other orga

Again, the surface alone may be approximated, leaving a deep hole in the vagina behind the perineum for the collection of blood and lochial discharges, and making a good culture medium for the generation of infective bacteria. In the majority of cases thus treated that have escaped infection, an examination after healing of the wound will reveal a thin layer of skin and mucous membrane taking the place of the perineal body.

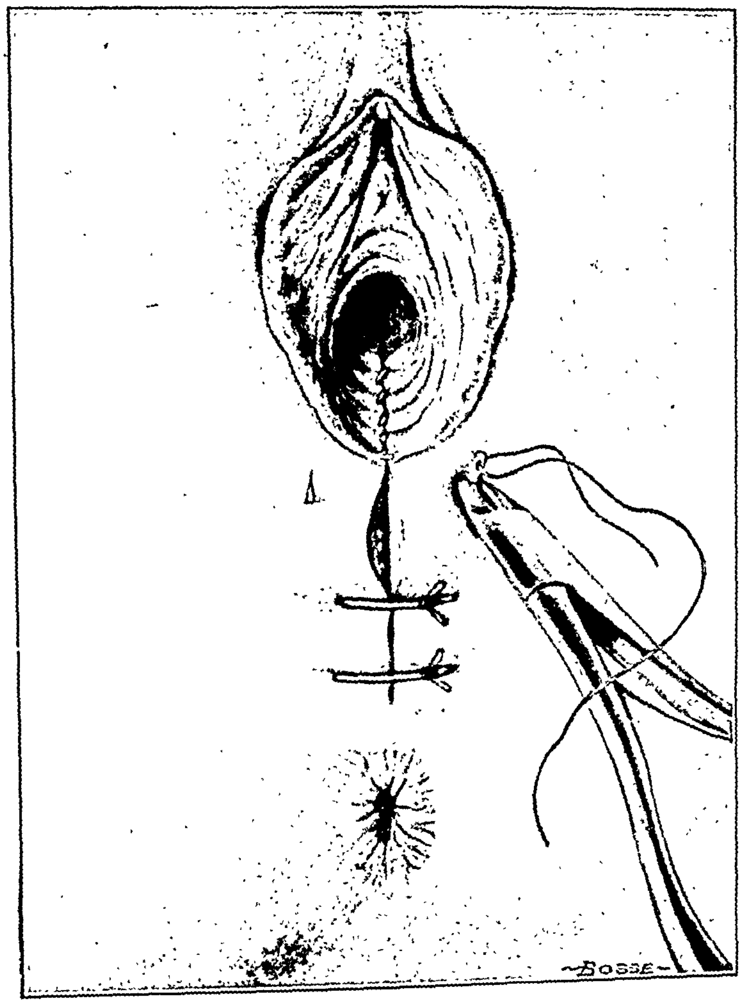

Fig. 3.—Operation completed.

In the repair of any ordinary wound, tissues of varying nature are brought together separately, and attempts are made to have as nearly as possible a normal alinement of the cut surfaces. To suture an ordinary wound without any regard to orderly rearrangement would be condemned by the veriest tyro in surgery.

The application of tenacula, to draw the different parts of the tear into correct position before starting, has been the first principle in all operations for secondary repair of the perineum, since the time of Hegar; but why this very important step is always neglected in the primary operation is not apparent.

TECHNIC OF THE OPERATION

The mucocutaneous edge of the wound at each side of the tear, where it enters the vagina, is caught up with a guide and traction suture. The operator or assistant, with regulated tension on these sutures, holds the wound open for inspection. The labia are widely separated, the wound is cleansed, bleeding points are controlled, and the torn edges of the muscles, which are generally represented by depressions in the side walls of the wound, are brought out with tenacula or temporary sutures, and joined with chromic catgut, and the number of interrupted sutures are made according to the requirements of the case. Before the muscles are brought together, the cervix may be exposed for inspection and repair.

After the muscles have been replaced, if the wound is deep, slack may be taken up in the connective tissue by one or two buried catgut sutures. With the guide sutures held in position for repair, the edges of the vaginal mucous membrane are now joined with a continuous chromic gut suture, and the outer side of the perineum is repaired with three or four silkworm-gut sutures deeply and widely inserted.

In complete tears, the rectal mucous membrane must be approximated first. The torn ends of the sphincter muscle are then brought out of the wound and firmly secured together, and the operation is completed as above.

It is important in complete tears that a rectal tube be inserted about 4 inches into the rectum, and retained there about four days. The bowels should not be moved during this time, and all discharges escaping through the tube should carefully be kept away from the wound, and the perineum should be disturbed as little as is compatible with careful cleanliness.

With the exception of third degree lacerations, I have seldom found it necessary to administer an anesthetic, though it is perfectly permissible to do so, especially if the patient is nervous or hard to control.

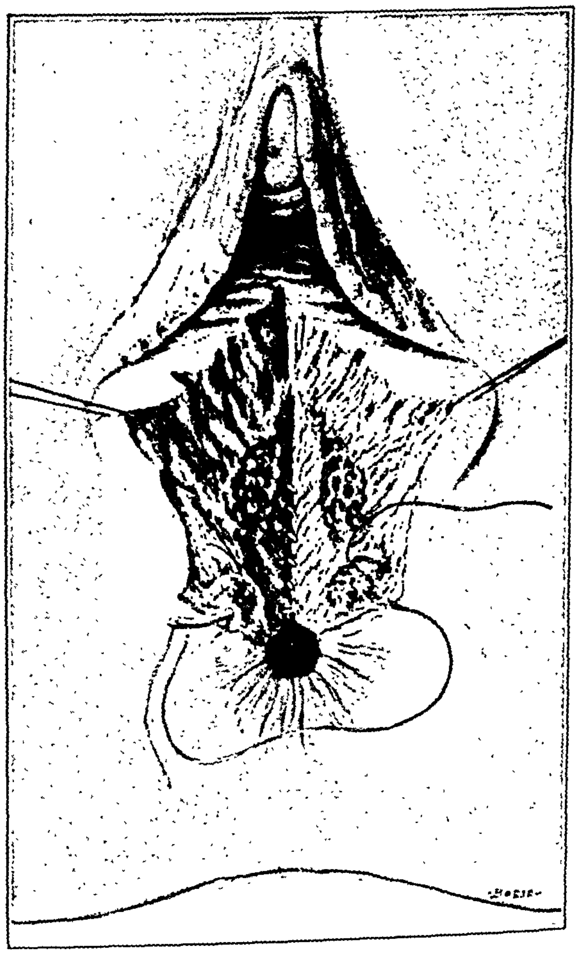

Fig. 4.—Rectal mucous membrane sutured, and suture inserted into torn edges of sphincter ani.

The method needs no special experience, and I believe that its simplicity of application is sufficient to recommend it. I would again call attention to the guide or traction sutures, which control the success of the operation.

139 West One Hundred and Nineteenth Street.

Clinical Notes, Suggestions, and New Instruments

A RAPID MACROSCOPIC AGGLUTINATION TEST FOR BLOOD GROUPS, AND ITS VALUE IN TESTING DONORS FOR TRANSFUSION

Beth Vincent, M.D. (Boston), France
Captain, Medical Reserve Corps, U. S. Army

Our knowledge of the four blood groups described by Moss[1] has proved to have a very practical value in blood transfusion. Hemolysis due to isohemolysis does not take place when the bloods of individuals of the same blood group are mixed in vivo or in vitro. It practically never occurs significantly in vivo when the donor belongs to a group whose red cells are not affected by the patient's serum in vitro, though the patient's cells in vitro may be acted on by the donor's serum. When the group has been determined, it is possible to select a donor whose blood is compatible as regards hemolysis with the blood of the recipient. Moss,[1] Minot,[2] Brem[3] and others have described practical microscopic tests for the determination of the blood groups. For the past two years, I have used a macroscopic test which is simple and rapid and sufficiently accurate for practical purposes. A brief review of some essential points will make clear the method and use of this test.

RELATION OF THE FOUR BLOOD GROUPS

		SERUM				
	Group:	I	II	III	IV	
CORPUSCLES	I	0	+	+	+	I
	II	0	0	+	+	II
	III	0	+	0	+	III
	IV	0	0	0	0	IV
		I	II	III	IV	

Every human being belongs to one of four blood groups. This grouping is based on the agglutinating activity of human serum and the susceptibility of red corpuscles of agglutination. The four groups formed on this basis are thus described:

Group I: Serum agglutinates no corpuscles. Corpuscles agglutinated by serums of Groups II, III and IV.

Group II: Serum agglutinates corpuscles of Groups I and III. Corpuscles agglutinated by serums of Groups III and IV.

Group III: Serum agglutinates corpuscles of Groups I and II. Corpuscles agglutinated by serums of Groups II and IV.

Group IV: Serum agglutinates corpuscles of Groups I, II and III. Corpuscles agglutinated by no serum.

There is no agglutination between serum and corpuscles of the same group.

The frequency of the four groups is, approximately: Group I, 5 per cent.; Group II, 40 per cent.; Group III, 10 per cent.; Group IV, 45 per cent.

The accompanying table shows the relation of the four blood groups (+ indicating that agglutination occurs, and 0 that no agglutination occurs).

The four blood groups are based on the agglutination reaction, but they also bear a definite relation to the action of hemolysins. The occurrence and reactions of the agglutinins do not vary. For example, they are always absent in Group I and always present in Group II; and Group II agglutinins always agglutinate corpuscles of Groups I and III.

As to the hemolysins, their reactions are constant in the groups which contain hemolysins, but their presence varies with the individual. For example, they are absent in Group I and may be present in Group III. Group III hemolysins always hemolyze corpuscles of Groups I and II, but Group III serum does not always give this reaction because the hemolysins are not found in the blood of every Group III individual. The hemolysins are present in only about 25 per cent. of all individuals. When present, the activity of the hemolysins follows the law that governs the activity of the agglutinins. For this reason the possibility of the presence or absence of the hemolysins may be deduced from the agglutination test.

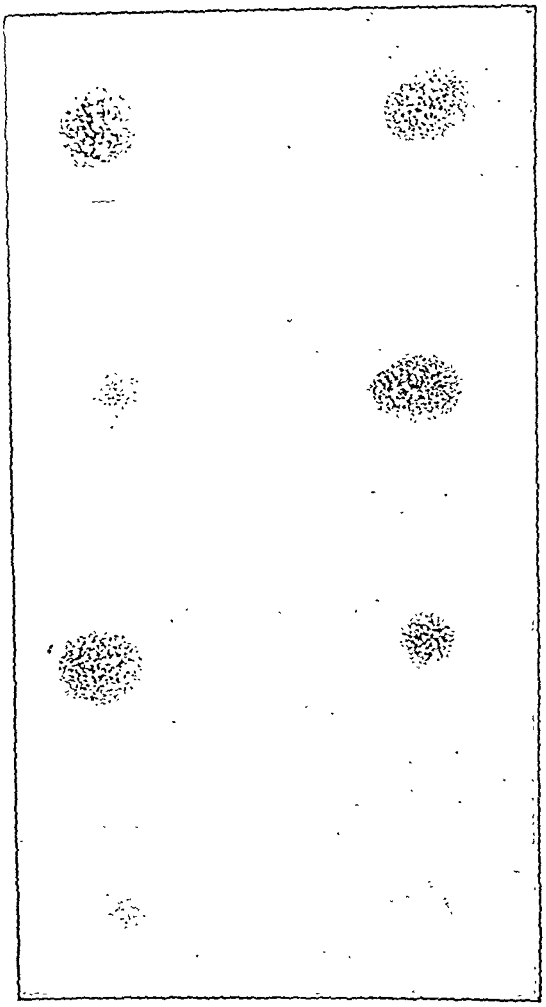

Fig. 1.—Group II serum is on the left-hand part of the glass slides, while Group III serum is on the right. Blood *from each of the four* different groups has been mixed with both II and III *serums. The top slide shows the agglutination of Group* I cells by both Group II and *Group III serums.* The second slide shows agglutination of Group II cells by Group III serum, but *not* with II serum. The third slide shows agglutination of Group III cells by II serum, but not with III serum. The bottom slide shows no agglutination of Group IV cells with either Group II or Group III serum.

Moss showed that the blood group to which an individual belonged could be determined by an agglutination test with his red blood corpuscles and the serums from individuals known to belong to groups II and III, or with suspensions of Group II and Group III red blood corpuscles and the individual's serum. All tests in use at present are based on this observation.

---

[1] Moss, W. L.: Bull. Johns Hopkins Hospital, *1910*, **21**, 63; 1911, **22**, 238; A Simplified Method for Determining the Iso-Agglutinin Group in the Selection of Donors for Blood Transfusion, The Journal A. M. A., June 23, 1917, p. 1905.

[2] Minot, G. R.: Boston Med. and Surg. Jour., 1916, **174**, 667.

[3] Brem, W. V.: Blood Transfusion, The Journal A. M. A., July 15, 1916, p. 190.

The macroscopic test described in this paper is made by means of two citrated serums, Serum II and Serum III, obtained from the blood of two individuals belonging to Group II and Group III.

To prepare the serums, 20 c.c. of blood are collected from each individual under sterile conditions. When the blood has coagulated and the clot has contracted, the serum is pipetted off into two sterile flasks, and sufficient sodium citrate is added to obtain a citrated serum 1.5 per cent., and some preservative, as tricresol, 0.25 per cent. The serum is citrated to prevent the coagulation of the small amount of fresh blood mixed with the serum in making the test, which would make it difficult to determine the presence or absence of agglutination. A preservative is used because it is desirable to keep the serum sterile, although I have observed, as have others, no apparent diminution in the activity of serum one year old which showed a moderate degree of contamination.

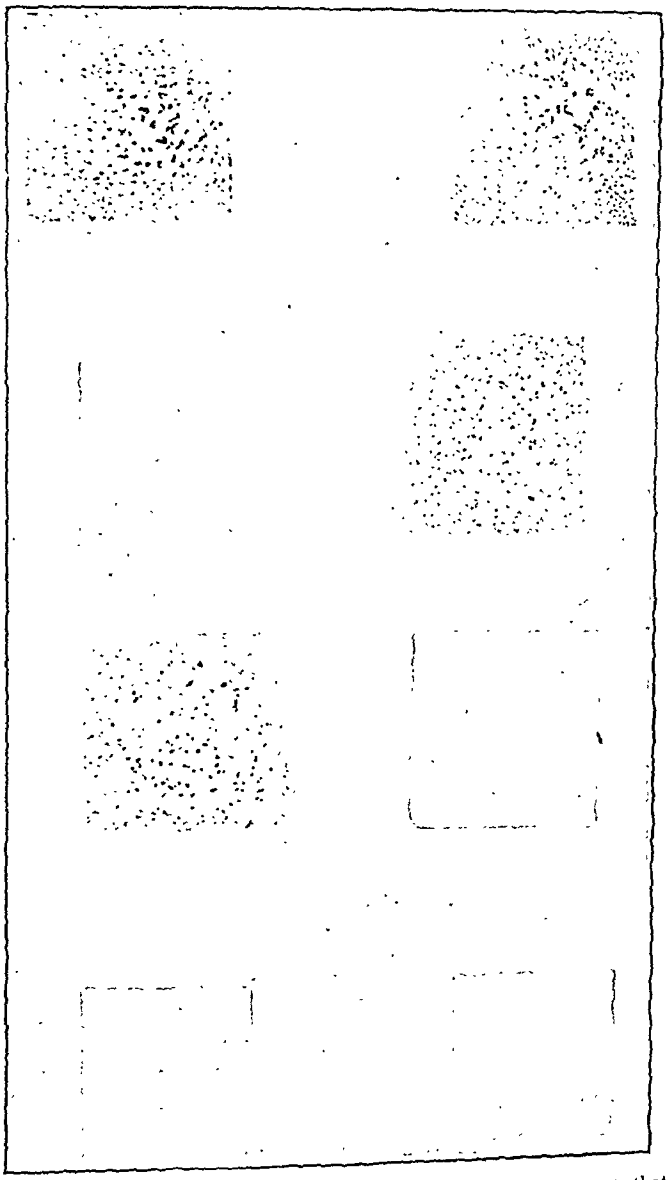

Fig. 2.—This shows the same results as in Figure 1 except that a cover glass has been superimposed on the mixtures of known serums II and III and the blood of the different groups.

The serums may be kept for use in sealed small glass tubes or in bottles stopped with a combination rubber cork and medicine dropper.

The two prepared serums and a clean dry glass slide are needed to make the test. One or two drops of Serum II is placed on the left half of the slide, and an equal amount of Serum III on the right half of the slide. The ear or finger of the person tested is punctured, and a small drop of blood is transferred on the point of a knife blade to each of the serums in turn. The blood is stirred into the serum. The blood should be transferred before coagulation has commenced, and care should be taken to avoid mixing the two serums. Agglutination of the corpuscles is accelerated if the serum it agitated by the slide's being tipped from side to side. If the reaction is negative, the corpuscles make a uniform suspension in the serum. If the reaction is positive, the masses of agglutinated cells usually appear in less than a minute and are readily discernible to the naked eye. With certain serums, rouleaux formation of the red corpuscles takes place and is sometimes confusing. Rouleaux formation usually appears more slowly than agglutination, and the rouleaux are broken up if the serum is disturbed, while agglutination is increased by this procedure. In doubtful cases, the reading should be confirmed by microscope examination.

Study of the photographic reproductions shows the method of reading the tests. Figure 1 shows the macroscopic appearance of the known serums mixed with the blood of the different groups (the preparations have dried slightly). Figure 2 shows the same combinations of serums and blood, on which a cover glass has been superimposed after the agglutination of the red cells became evident. If the reaction is negative with both Serum II and Serum III, that is, a persistence of a uniform suspension of corpuscles, it indicates a Group IV blood. If the reaction is positive with both serums, that is, agglutination of the corpuscles, it indicates a Group I blood. If negative with Serum II and positive with Serum III, it indicates a Group II; and if positive with Serum II and negative with Serum III, it indicates a Group III blood.

It will be observed that these four different combinations of reactions conform to the two middle columns (between the heavy lines) in the table. If a slide is superimposed on its proper row in these columns, the group number of the corpuscles at the end of the row corresponds to the blood group of the individual tested.

Except in cases in which the risk of delay is greater than the risk of hemolysis, the compatibility of the blood of donor and recipient should be determined before blood transfusions are performed. While the compatibility of donor and recipient may be ascertained by testing the different serums and corpuscles in each instance against each other, this end is reached much more quickly and more easily if the blood groups of the individuals are known. Hemolysis of the red corpuscles does not take place between members of the same group. Therefore, when possible, it is preferable that donor and recipient should belong to the same group. Recent clinical experience apparently has confirmed the fact that certain definite combinations of different groups can be made without danger of hemolysis. Under certain conditions the red cells are protected by the antihemolysins, the absorption of agglutinins by the red cells and other factors which need not be explained at this time. Suffice it to say that members of Group IV may be used as donors for individuals belonging to Groups I, II and III, and that a Group I recipient may be transfused from individuals belonging to Groups II, III and IV. Members of Group IV, therefore, are termed universal donors, and members of Group I, universal recipients.

The selection of donors by blood groups is made as follows:

A Group I recipient may be transfused from any group. Group II and III recipients may be transfused from the same group or Group IV.

A Group IV recipient requires the same group.

CONCLUSIONS

From the foregoing it is evident that the agglutination tests to determine blood groups have a very practical application in blood transfusion.

The macroscopic test is especially valuable because it is simple, rapid, and sufficiently accurate for practical purposes.

Girls and Khaki.—The social hygiene problem created by this war is not a problem of commercialized prostitution. Segregated districts, disorderly houses and professional women have been very largely removed from the cities and towns near our training camps. It is a problem of the individual soldier and the individual girl—the man cut away from his ordinary amusements and social life, the girl responding to the unusual and romantic glamour of the uniform.—Winthrop D. Lane, the *Survey*.

A MODIFICATION OF THE MOSS METHOD OF DETERMINING ISOHEMAGGLUTINATION GROUPS *

A. H. Sanford, M.D., Rochester, Minn.

It is well known that the iso-agglutinins in human serum are thermostabile, and it occurred to me that agglutinating properties in human serum might be easily preserved by drying. The experiment was made as follows to determine this point: Cover slips were cleaned and dried. On several of these were placed two loopfuls of serum from persons of Group III. In like manner cover slips were prepared, with serum from Group II persons. These droplets of serum were allowed to dry in the air, and were then wrapped in paper and placed in the ice box. After more than two months they still possessed marked agglutinating properties. To demonstrate this, one loopful of corpuscle suspension of a Group II person was used to dissolve the dried Group III serum on one of the cover slips. When this was inverted over the cavity on a hanging drop slide, it was noted that agglutination of the cells occurred almost immediately, as in the Brem method.[1] When the corpuscle suspension of the same group as the serum was used to dissolve the dried material on the cover slip, no agglutination occurred. Since we are asked from time to time to send known serums to laboratory workers who contemplate using either the Moss[2] or the Brem method for determining groups in the selection of donors for transfusions, it would seem that this method of using dried serum could well be employed in two ways:

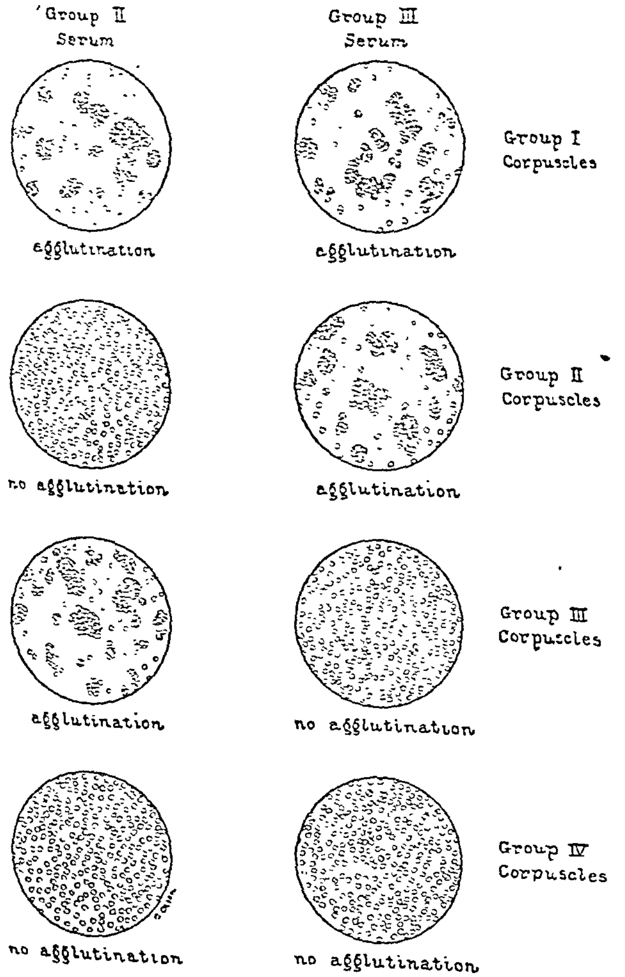

Fig. 1.—Appearance of hanging drop preparations of corpuscle suspensions of four different groups (Moss classification) used to dissolve Group II and Group III serum dried on cover slips.

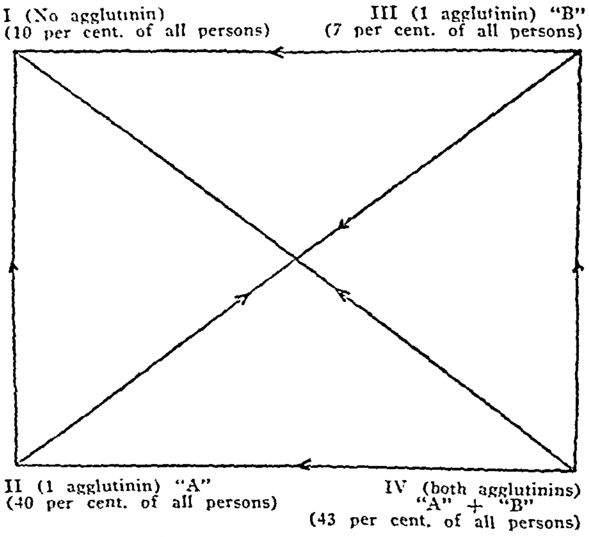
1. The group in which a patient belongs might be determined by preparing several cover slips with serum of the person to be tested. These could be sent to a laboratory equipped to make the necessary tests, and by dissolving the dried serum with corpuscle suspension of a known group the patient's group would be readily determined. The technic is to dissolve the serum on one cover slip with one or two loopfuls of suspension of Group II corpuscles made by allowing two or three drops of blood from a Group II person to fall into 1 c.c. of 2 per cent. sodium citrate solution. Another cover slip preparation may be made by dissolving the serum from a loopful of Group III corpuscle suspension. Hanging drop preparations are then made and examined under the microscope. Agglutination of corpuscles on both slides places the unknown serum in Group IV. No agglutination after ten minutes on either slide places the unknown serum in Group I. Agglutination of the Group III corpuscles and no agglutination of the Group II corpuscles places the unknown in Group II, and agglutination of the Group II corpuscles and no agglutination of the Group III corpuscles places the unknown in the reciprocal Group III.

2. This method may be used very well by laboratory workers who desire to start grouping unknown blood and who must have known serum for beginning these tests. The technic is to collect from the unknown person a few drops of blood in 1 c.c. of 2 per cent. sodium citrate solution to make a corpuscle suspension similar to the method described by Brem. One or two loopfuls of unknown corpuscle suspension is used to dissolve the Group II serum dried on the cover slip marked known Group II serum. In like manner a drop of the corpuscle suspension is used to dissolve the dried Group III serum. Hanging drop preparations are made and examined in the usual manner. Agglutination on both of the slides will place the unknown blood in Group I. No agglutination on either of the slides after ten minutes will place the person in Group IV. Agglutination of the unknown corpuscles with Group III serum and not with Group II will place the unknown in Group II and vice versa. Group III blood is demonstrated by agglutination with the Group II serum and no agglutination on the other side. Reference to the diagram for the relation of the agglutination groups to each other (Fig. 2) may be helpful in following the technic of this test.



I (No agglutinin)
(10 per cent. of all persons)

PNEUMOPERICARDIUM FOLLOWING PARACENTESIS: REPORT OF A CASE

Charles E. Stewart, M.D., Battle Creek, Mich.

History.—R. J. B., man, aged 39, evangelist, was admitted to the sanatorium, May 2, 1916, complaining of pain in the right side, dyspnea and progressive weakness. His father died at 60 from the grip, his mother at 47 from malaria. One maternal aunt died from pulmonary tuberculosis. His wife and four children were in good health. In early childhood he had intermittent fever, and frequent attacks of colic and diarrhea.

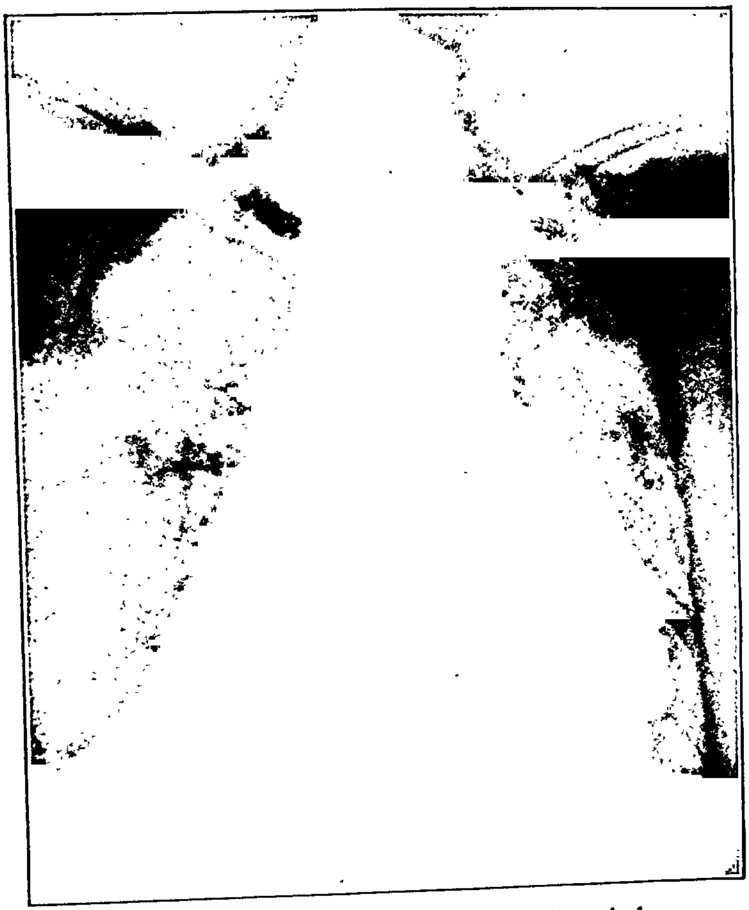

Fig. 1.—Condition of chest on patient's arrival.

Six years before admission, his health began to fail. At that time he had a persistent cough, and on examination pulmonary tuberculosis was suspected and he went west, where he gradually regained his health. Later he returned to his home in Texas, where he resumed his work. He continued in apparently good health until three years before, when he had an attack of acute appendicitis, and the appendix was removed. At the time of operation, numerous adhesions were found about the intestine.

A few months later he had a severe attack of pain in the right upper abdominal quadrant. This was accompanied by fever and lasted twenty days. After this he was free from pain for several months. During September, 1915, the pain returned again, but was not quite as severe as during the former attack, but had continued ever since.

He complained of tenderness along the margin of the right costal arch and the hepatic area. He described this as being very sore, with a dull ache. He had coughed a great deal during the past four months, and breathing was jerky and difficult. He had expectorated very little, appetite and digestion were good, but eating produced discomfort in the right upper quadrant and greatly increased his dyspnea. He complained of weakness and pronounced dyspnea on slight exertion. During December, 1915, he fainted twice. He had chewed a great deal of tobacco, having used it continuously for thirty years.

Physical Examination.—The temperature was 98.2, the pulse 126, small and weak. The patient's frame was of medium size. Nutrition was subnormal. The musculature was small and flabby. The skin generally was dark. There was some cyanosis about the face and the fingers. The neck vessels were engorged. There was a scar over McBurney's point. The pupils were wide. The tongue was heavily coated. The chest was small; expansion was limited; respirations were rapid and shallow; there was an expiratory grunt. Breathing was labored and less rapid when the patient was sitting or standing than when lying down. There was dulness over the left apex anteriorly and posteriorly. Crepitant râles were heard over the entire pulmonary area anteriorly and posteriorly, and were most pronounced anteriorly. Bronchial breathing was heard over both sides.

On percussion a large area of cardiac dulness was encountered, extending from the fifth interspace on the left side of the thorax in the anterior axillary line to the midclavicular line in the fifth interspace on the right, gradually diminishing in breadth in an upward direction until the area of the great vessels was reached, where the breadth of dulness was a little wider than normal. The area of dulness was triangular, with the base downward about two thirds to the left and one third to the right of the sternum. When the patient lay on the right side, the area of dulness shifted about 2 cm. to the right. The cardiohepatic angle, instead of being an acute one, as in the normal, was quite obtuse. On auscultation over the precordia, no adventitious sounds were heard; the heart sounds were all quite distinct. Palpation was negative, no cardiac impulse being felt.

The contour of the abdomen was normal except for a slight bulging beneath the right costal arch, over which area there was tenderness most pronounced in the region of the gallbladder. The hepatic dulness extended to within an inch of the umbilicus. During expiratory movements the area of hepatic excursion was limited.

The urinary findings were negative except for the presence of a large quantity of indican. The blood was negative; the systolic blood pressure was 90, diastolic 64, pulse pressure 26. Examination of the sputum revealed the presence of tubercle bacilli. The electrocardiogram showed a right sided preponderance.

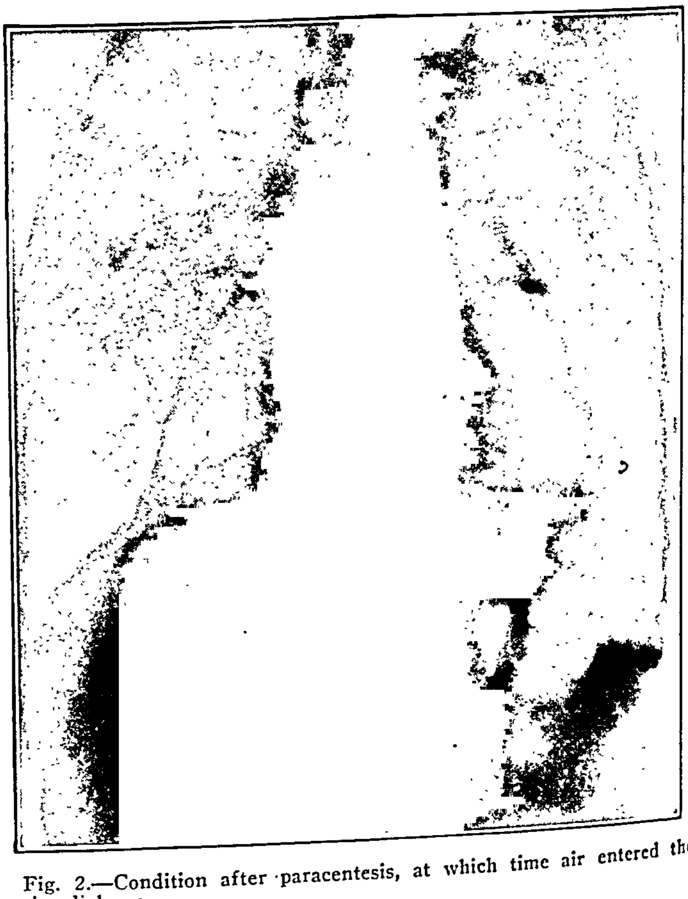

Fig. 2.—Condition after paracentesis, at which time air entered the pericardial sac.

The large area of precordial dulness shifting on change of position, absence of cardiac impulse on palpation, the obtuse cardiohepatic angle, and the presence of extensive pulmonary changes, together with the presence of tubercle bacilli in the sputum, led to a diagnosis of pericardial effusion of tuberculous origin.

A fluoroscopic examination revealed a tremendous heart, which reached within a thin finger's breadth of the left chest wall. The right border of the heart reached midway between the midline and the right chest wall. The shape of the heart was somewhat suggestive of a pericardial effusion, although the vigor of the pulsations of the cardiac shadow was against fluid. There was a moderate increase in the width of the aortic shadow, the increase being both upward and laterally. The left bronchus was pushed upward by the enlarged heart. The right diaphragm seemed normal. The left costophrenic angle was obliterated, apparently by a small amount of fluid.

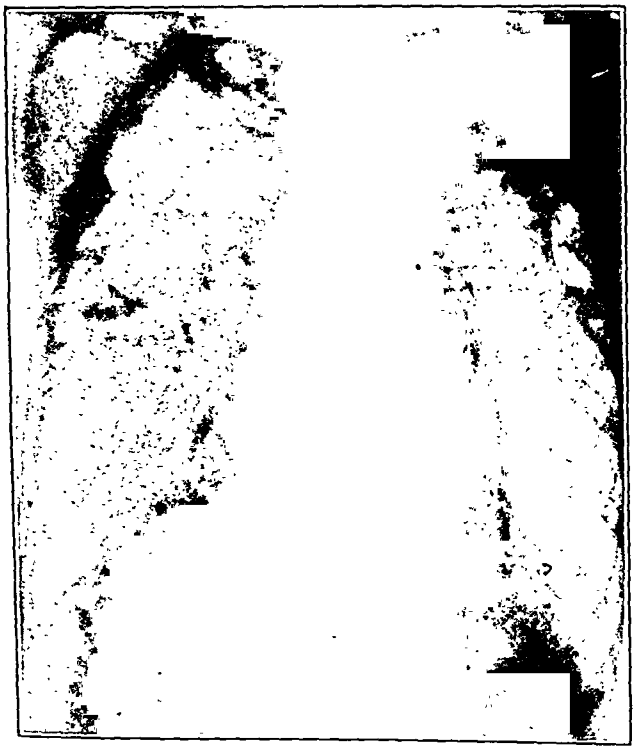

Fig. 3.—Condition after a second paracentesis, at which time no air entered.

In the right lung anteriorly there was degeneration of the subcutaneous tissue to the lower border of the fifth rib in the midclavicular line. Over the same area moist râles were obtained. There was moderate retraction of the apex. Posteriorly there was dulness from the apex to the upper border of the ninth rib close to the spine. There were moist râles as low as the upper border of the sixth rib. From here to the lower border of the eighth rib close to the spine the breathing was decidedly bronchial in character. There were emphysematous changes at the base.

In the left lung anteriorly there was dulness from the apex to the lower border of the second rib, with harsh inspiration and bronchial prolonged expiration. Between the second and third ribs the percussion note was more resonant although the râles continued to and around the cardiac dulness. From the third rib extending to the base the percussion note was more flat. The cardiac dulness extended around into the axillary area. There were some pleural crepitations at the base of the lung, where the roentgen ray suggested possible fluid. Posteriorly there was dulness to the lower border of the sixth rib, with bronchial prolonged expiration over the same area. Between the second and fourth ribs the breath sounds were decidedly bronchial in character and accompanied by râles. There were emphysematous changes at the base.

Summary.—There was a very marked enlargement of the heart, with some findings suggestive of pericardial effusion. Some changes throughout the lung could be caused by the venous congestion due to circulatory disturbances, but apart from this there had been an old tuberculous process in both lungs, which now showed signs of activity in the upper part of each lung, more particularly marked in the right.

Treatment and Course.—May 15, the patient was sent to the hospital for paracentesis of the pericardium. At this time an ordinary aspirating needle was inserted through the fifth interspace an inch to the outer side of the midaxillary line, and 22 ounces of fluid were withdrawn. During this procedure air was accidentally allowed to enter the pericardial sac so that it remained as much distended as it was prior to the removal of the fluid.

Figure 2 gives a beautiful illustration of this, showing the sac containing air and also the level of the remaining fluid. A fluoroscopic examination of the chest at this time revealed a very interesting condition: the distended pericardium with the heart inside of it, and the level of the fluid on the two sides of the heart shadow. The fluid level was in constant agitation, alternately rising and falling on either side of the heart as it changed its position and size during systole and diastole.

For a period of two weeks after the removal of the fluid the patient made rapid improvement. Shortly after this the pericardium rapidly filled with fluid again and the old symptoms of dyspnea, cough, cyanosis and tachycardia returned June 11, paracentesis was again performed, and 14½ ounces of fluid were removed but did not afford much relief. After a few days the patient rapidly grew worse, and he died about two weeks after the last fluid was withdrawn.

Figure 3, showing the heart after the fluid was removed the second time, shows that the pericardium on the right side was adherent to the diaphragm as far out as the midclavicular line, and this may account for the constant pain the patient experienced in the right upper quadrant.

GONOCOCCUS INFECTION OF THE MUCOUS MEMBRANE OF THE ORAL CAVITY

John Mills Mayhew, M.D., Lincoln, Neb.

History.—N., a student, aged 19, had always been in good health. He denied venereal disease or recent exposure of any kind. Jan. 2, 1918, the day before his departure from his home at Sheridan, Wyo., to attend a college in Massachusetts, he visited a dentist to have his teeth cleaned. He reported that the dentist was so rough that his mouth bled in several places after the treatment. Within twenty-four hours he had a great deal of pain and a burning sensation in the buccal portion of the lips, and within forty-eight hours his throat was sore. Sixty hours after the treatment his lips were swollen and painful, and vesicles formed at the corners of the mouth. He could not swallow anything but the blandest of liquids, and even warm water hurt his throat severely. I saw him four days after the trouble began —five days from the time of infection. He complained of intense pain in the throat and under the tongue; he could hardly move his lips in speaking, they wer [illegible] ollen.

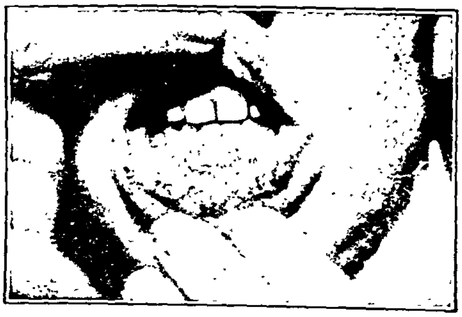

Fig. 1.—Infection of lower lip.

Examination.—This was difficult, [illegible] n of t entire buccal cavity was the right pillars and velum, and a white, clinging exudate over the left velum, cheeks, lower lip, dorsum of the tongue, and oropharynx. On the frenulum of the tongue there was a shallow ulcer with a red base resembling somewhat a mucous patch. The corners of the mouth were cracked and bleeding. The area under the exudate on the lips bled when the membrane was raised. The tongue was swollen, and showed an exudate on the dorsal surface. The whole picture presented a most severe type of mouth infection. The submaxillary glands were swollen and tender; the cervical chains were negative. The temperature was 100.2, the pulse, 110. The patient felt and looked very ill. Serum from the ulcer on the frenulum was examined with the dark field illuminator, and by means of India ink smears for the *Spirochaeta pallida*, but none were found. Specimens were taken from different parts of the mouth and were examined especially for Vincent's spirochete, the fusiform bacillus, and fungi. Smears made from the pus revealed gram-negative, biscuit-shaped diplococci, both intracellular and extracellular. A large number were crowded in some of the leukocytes, one containing fourteen pairs. This organism grew slowly on ascitic fluid, hydrocele and blood serum-glycerin-glucose-agar, and did not grow on the simple cultural mediums at 37 C. It was agglutinated by serum from a known gonorrheal blood. Complement fixation for gonorrhea was negative, but since this is usually the case in acute gonorrhea, I did not put much value on this test. It seemed to me, reasonable to believe that this organism was the gonococcus.

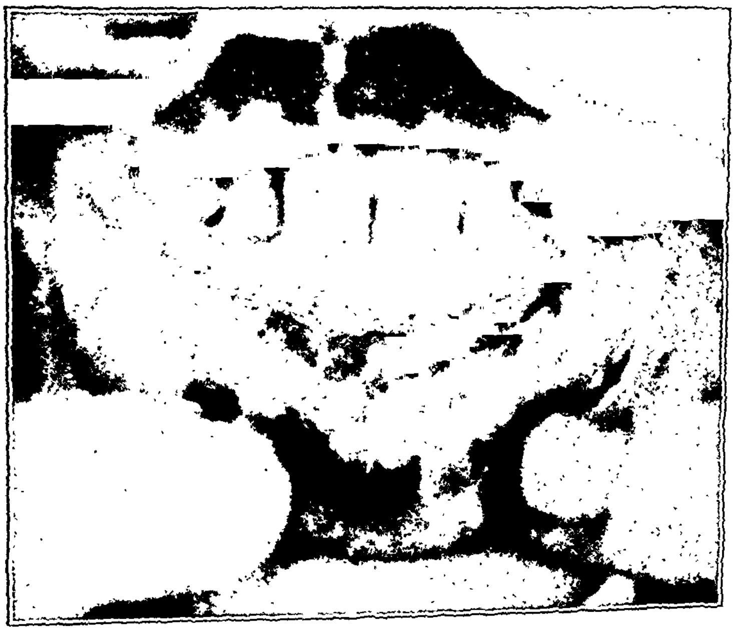

Fig. 2.—Exudate on upper and lower lip.

Treatment and Course.—The patient was sent to the hospital, isolated, and treated with a mouth wash of a saturated solution of thymol. The mouth and throat were swabbed twice daily with a 2 per cent. silver nitrate solution. The exudate increased rapidly, covering the roof of the mouth and the lips and evading the tonsils, but appearing on the pharynx by the morning of the following day, the eighth after infection. In forty-eight hours after treatment was instituted, the exudate began to disappear, leaving a raw, bleeding surface, the roof of the mouth clearing first, then the pharynx and lip surfaces in order. The ulcer on the frenulum was the last to heal. At no time was there any odor from the mouth or the secretions expectorated. Smears were negative for the intracellular diplococcus on the twelfth day, and none of the organisms described were found in culture; but the mouth was very sore and, in places, raw, and it bled on slight provocation. The parotids were not painful at any period of the disease, the cervical lymphatics were but slightly tender, and the joints were never disturbed. The nasopharynx mucous membrane and nasal cavities were not infected.

It is known that the gonococcus will attack any mucous surface, but it has been found rarely in the mouth. While this attack followed the supposed infection too closely to be an ordinary gonococcal infection, it seems to me that the only other organisms, the meningococcus and the *Micrococcus catarrhalis*, have been excluded as an etiologic factor.

REMOVAL OF THIRTY DENTICLES FROM ONE BICUSPID SOCKET

Bundy Allen, M.D., Iowa City, Iowa
Roentgenologist, University Hospital, State University of Iowa, College of Medicine

May 29, 1917, a woman, aged 23, called my attention to a slight prominence of the gum buccally to the upper right bicuspid region which had not produced any symptoms other than the elevation of the tissue. Figure 1 is a roentgenogram of the upper right bicuspid region showing the presence of a collection of denticles. The patient was referred to Dr. John Voss of Iowa City, Iowa, who extracted thirty denticles from the first bicuspid socket (Fig. 2). All teeth were present, and occlusion was perfect, excepting for the third molars, which had not erupted.

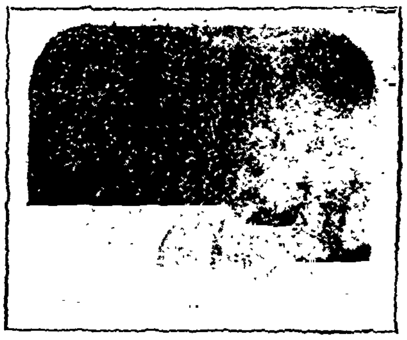

Fig. 1.—Collection of denticles in upper right bicuspid region.

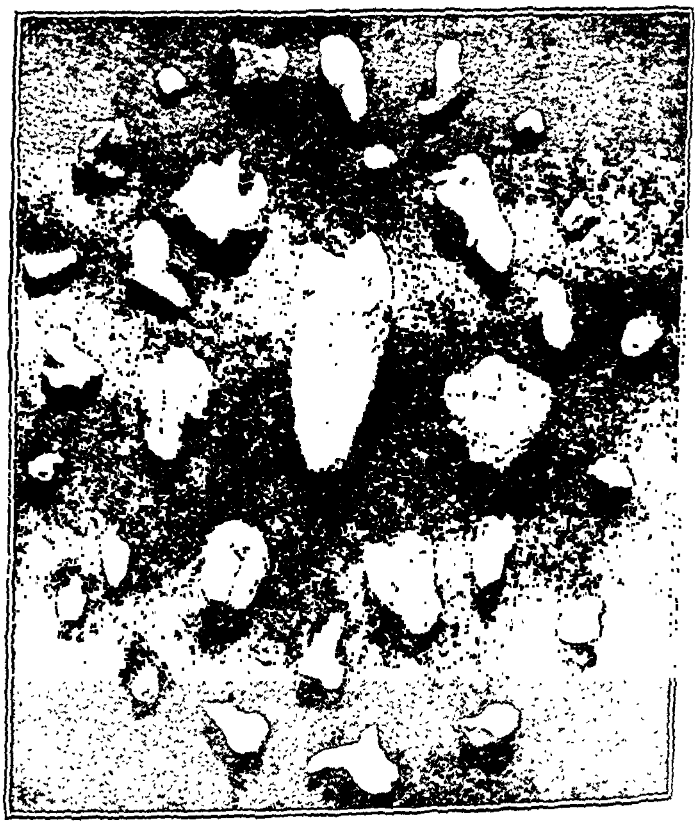

Fig. 2.—The thirty denticles removed from the bicuspid socket.

Child Labor Standards.—To secure ideal standards, national or local, we must presuppose ideal citizens, educated, alert, knowing what they want and organized to demand efficiency of their public servants.—Lindsay, *Child Labor Bulletin.*

HOW TO BREED MICE*

Conrad Hon, New York

In breeding mice, one should be sure to use strong, healthy animals. If the mice are obtained from an unknown stock, they should be isolated for two weeks, and if any of them become sick during this time they must be discarded. Unless this precaution is taken, an epidemic will devastate one's own stock.

At the time of mating, the female mice should be from 8 to 10 weeks old, and should weigh from 17 to 18 gm. The males should be from 8 to 10 weeks old, and should weigh at least 20 gm. The period of gestation of the mouse is about twenty-one days. The average litter is five, although some females give birth to as many as twelve. It is best not to put more than four females with one male. The males should not be used more than three or four months, while the females should be discarded after they have borne four or five litters.

There are two ways of breeding mice: the family group method and the individual method. In the former method, four females are kept in a box with one male. The advantages of this method are that not only is less labor and space required, but the females have a litter every thirty days. The disadvantage is that one of the females may be vicious and kill not only her own offspring, but all the other young mice in the box. In the individual method, four or five females are also placed with one male, but as the females become pregnant, they are put into separate boxes. The disadvantages of this method are that more time and space are required, and the gestation period is lengthened forty-five days. This method is preferred, as more and healthier mice can be raised.

The temperature of the breeding room should be kept between 68 and 70 F. The mice may be kept in wooden boxes or in glass battery jars with wire tops. A box measuring 11 inches long, 8 inches wide, and 5 inches deep is the most convenient. It is much easier to clean the wooden boxes if their bottom is lined with tin. The battery jars measure 6 inches in diameter and 8 inches in height. The bottom of each box or jar should be covered with sawdust or shavings to the depth of 1 inch. The sawdust or shavings should be changed at least twice a week. Both boxes and jars should be thoroughly cleaned with soap and water twice a week. If an infectious disease breaks out, the boxes and jars should be sterilized. When the mice become pregnant, a handful of fine hay or paper cut into strips is put into the boxes.

The young mice can usually be weaned in three weeks. In large litters, it is better to wean the stronger ones at the end of three weeks, and allow the weaklings to remain another week. As soon as the young are weaned, the females are returned to the males.

Mice should be fed twice a day. The morning meal should consist of moist food, such as bread soaked in skimmed milk. If skimmed milk cannot be obtained, boiled whole milk diluted with an equal quantity of water may be substituted. If milk is unattainable, bread should be soaked in water. An evening meal of grain is given, a mixture of wheat screenings and buckwheat, or buckwheat and oats, or oatmeal is used. Dog biscuit should be fed twice a week. The dog biscuit is not only highly nutritious, but keeps the mice from gnawing at the boxes.

The mice should be inspected daily. If a mouse shows evidence of disease, it should be immediately isolated, and if severely affected, it should be killed at once. There are two highly infectious diseases that affect mice. Mouse typhoid is easily recognized by the diarrhea that is present. The mouse appears sick, the fur is ruffled, the eyes bulge, and a peculiar odor is noticeable. There is another highly contagious condition of unknown origin which causes paralysis and definite swelling of one or more limbs. This condition causes death in about two days.

The three cardinal rules of a successful mouse breeder are cleanliness, close observation, and isolation.

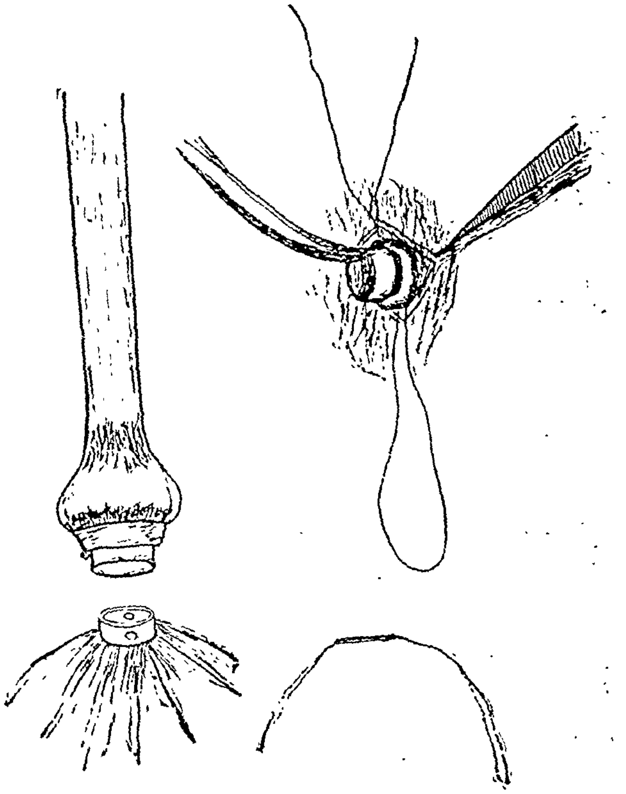
A NEW TECHNIC FOR BLADDER DRAINAGE

Harvey P. Jack, M.D., Hornell, N. Y.

This technic is an adaptation of the use of the Murphy button, similar to its use in enterostomy, as suggested by Dr. William D. Johnson of Batavia, N. Y. As will be noted, one half of the Murphy button is inserted into the end of a large rubber tube, the rubber end surrounding the button closely about its shank, just as the end of an intestine would be made to surround it by the purse-string in end-to-end anastomosis. The other half of the button, surrounded down to its shank by a soft rubber ring, if desired, so that it will not cut through too quickly, is placed inside the bladder through a small slit. The bladder tissues are brought firmly about the shank of this half of the button, and the two halves are pushed together as closely as desired. It will be noted at once that we have a perfect joint and that we may use our drain as little or as much as we please. If we are not satisfied that we are perfectly siphoning all of the bladder cavities, of which a strong point is made by Deaver,[1] we may readily introduce another and smaller tube, threading it through the larger one down to the very bottom of the bladder. Forty-eight hours after this operation, which is performed under local anesthesia usually, quinin and urea hydrochlorid four-hour washings of the bladder are begun. If the patient desires to be up and about, an artery clamp is placed on the tube, and he is given the desired permission.



Appliance for drainage of bladder.

In the last ten cases of prostatectomy we have used this device with the utmost satisfaction. No leakage occurs, and at the end of the preoperative period the suprapubic wound in every case had healed by first intention.

The device has saved much suffering by its prevention of that justly dreaded bugbear of suprapubic wounds, infection of the space of Retzius.

Another advantage this technic presents over any of those recently suggested is that the incision in the bladder may be made of sufficient length to allow search for and removal of stones, which should always be done. At the same time a nonleakable joint is easily secured by a purse-string suture which brings the bladder tissue about the half of the button placed in the bladder. This, of course, is the female half of the button.

---

[1] Deaver, J. B.: Ann. Surg., 1917, 66, 371.

I have never yet used the rubber ring suggested above. The button has always remained in the tissues without cutting for two weeks. Should it be desired to keep the button in place for a much longer period, the use of the ring is obvious.

Military Medicine and Surgery

TRAINING THE ENLISTED PERSONNEL OF A BASE HOSPITAL

EUGENE S. KILGORE, M.D. (San Francisco)
Major, M. R. C., U. S. Army; Base Hospital No. 30
(University of California), A. E. F.

The scheme for organizing the first fifty base hospitals for the new United States Army by the Red Cross in conjunction with civil hospitals and medical schools, had for its primary object the suitable grouping of specialists. A less obvious result, but another important one, has been the selection for these units of a relatively high percentage of enlisted men with college and other special training. Instead of simplifying the process of training, which at first would appear to be the result of such selection, the problem has really been made more complicated. For, while the courses in nursing, first aid, etc., ordinarily prescribed for sanitary troops are quickly covered by men with these qualifications, such training is inadequate, for the reason that it falls short of preparing them as well as they can be for the special work of a base hospital. Our method of meeting this situation is here outlined.

The first step, which was taken before the mobilization of the unit, was, by means of a questionnaire and a personal interview with each man, to make a survey of the personnel. The result of this was expressed on a large chart, exhibiting, in parallel columns, the names of the men; their education; their previous employment; their previous experience in the Army, in hospitals, in commercial and professional pursuits, etc., and our personal impression of their character.

This survey was used as a basis for the assigning of men for special training. It showed a large percentage with college training, including a number of premedical and first year medical students, graduate students in protozoology, etc., and others with previous military training, mostly in schools.

Several months prior to mobilization, five men were assigned to active duty through request made to the department surgeon. These were selected as prospective noncommissioned officers. Several others volunteered during this time to serve as hospital helpers, and quite a number were able to attend an evening drill class.

Systematic training was not attempted, however, until the men were mobilized and under definite military control. Our organization, under command of Col. Elmer A. Dean, was fortunately situated in San Francisco at a point readily accessible to four large teaching hospitals, the Letterman General, Lane Hospital, the San Francisco Hospital, and the University of California Hospital, in all of which the utmost courtesy and helpfulness was encountered.

The men were at once divided into five detachments, one to remain in camp, which included the necessary camp help, and four to attend hospitals. Each hospital detachment was placed in charge of a medical officer for general oversight and instruction. Special pains were taken in these assignments, first, to limit the number of men in any one place to those who could actually be used as part of the hospital help; and, second, to fit into specially important places men capable of qualifying for them. For the latter purpose the tabulated survey of enlisted personnel was particularly useful. The following will serve as examples: Two medical students who had studied physiology were made apprentices to two different anesthetists, and after a sufficient period of instruction they were allowed to work under supervision and then to work entirely on their own responsibility. Another medical student in the same way has become a competent serologist, able independently to carry out the technic of complement fixation for syphilis, gonorrhea and tuberculosis, to test blood for transfusion, to do the more technical tests on spinal fluids and other similar work. Another group of men with previous experience as microscopists have learned to do the work of a routine clinical laboratory, including examination of the urine, feces, blood sputum, etc. Several have become valuable assistants in bacteriologic and pathologic laboratories. Soldiers also have been adequately developed as assistants in roentgenography, the genito-urinary room, the surgical clinic, the operating room, the sterilizing room, the diet kitchens, etc. In addition, a large number of men were used in medical and surgical wards as orderlies and nurses' helpers. Those assigned to the Letterman General (United States Army) Hospital were taught particularly Army ward management and paper work.

One or two general changes in assignments to hospital wards were made during our three months in camp, so that the majority of the men received more than one type of training; but this did not apply to the "special training" men (anesthetists, laboratory workers, and the like). *An essential part of the plan was to train these men intensively in one subject only.*

With most of the company thus scattered and their time so fully occupied, special measures were necessary to secure the desired proficiency in military drill. The plan adopted worked out even better than our hopes. Noncommissioned officers distributed so that two or three were with each hospital and camp detachment were charged with the responsibility to see that every man learned the drill. Their instruction was controlled and unified by means of weekly conferences. They were required to submit in tabular form the reports of the accomplishments of each man in such fundamentals as the position of the soldier, the facings, ability to maintain the 30 inch step, the half step and the proper marching cadence, and the movements of pivot men and guides.

Of considerable assistance in quickly mastering these movements was a series of full size diagrams painted on some neighboring and little used asphalt streets. These showed by lines the direction of march and by cross marks the steps taken by individuals in such fundamental evolutions as "Detachment Right," "Right Turn," "Fours Right About" and "Right by

Fours." Individuals and groups used these diagrams for practice at such odd hours as they could find until they could be marked proficient. With this foundation the company drill, which was held as a rule but once a week, succeeded in a very short time — much shorter, we believe, than is required by the usual methods of straight detachment drilling. We also believe that the results are better.

An important factor in the success of this drill teaching as well as of the training as a whole was competition for promotion. We were fortunate in having enlisted the men almost without exception as privates; and, while not overlooking educational qualifications, we early announced the policy of making promotions on the basis of demonstrated fitness. Only two or three experienced noncommissioned officers were drawn from the Regular Army. Those who assisted in the drill teaching, although they had had previous military instruction, received at first merely temporary appointments as lance corporals. Evening classes in Army regulations, clerical work, etc., were held for those who wished to attend in preparation for the examinations for noncommissioned officers.

SUMMARY

In training the enlisted personnel of an Army base hospital, the following have been found highly advantageous:

1. Situation of the camp near large teaching hospitals.
2. Initial survey of personnel to discover fitness for special work.
3. Under adequate supervision, assignment of individual men or very small groups to wards, laboratories and other stations for training. In no place in the hospital should more men be placed than can actually be put to work.
4. Nonrotation of men learning technical work.
5. Military drill instruction with expenditure of less time and more individual effort; organization of student teachers, supplemented by conferences, and use of marching diagrams.
6. Stimulation of competition for promotion on basis of fitness shown in work and in examinations.

The Plague of Scabies.—French dermatologists have been recently calling attention to the increasing prevalence of itch, and in his address on assuming office, the new president of the Lisbon Sociedade das Sciencias Medicas, Dr. Z. Falcão, mentioned also the plague of scabies. He stated that in his service last year at the S. José Hospital, 3,234 persons with scabies were given treatment, and the numbers are much higher this year. In one day recently there were forty-six cases, and cases are multiplying in his private practice. In infants, and exceptionally in adults, intercurrent scabies renders eczema or impetigo much graver and complications may prove fatal. Adults with visceral lesions suffer from the insomnia from the "mysterious itching," and serious consequences have been observed from the chilling of the body as it was exposed for scratching. The nervous may develop actual obsessions. Scabies lesions on the penis open the portals to infection, especially to virulent syphilis. Another distressing localization of the itch is in the areola of the mamma; this, he said, has been known to lead to suicide. He also related that the irritation of the skin from extensive scabies and from the various topical measures applied, may damage the kidneys. He has frequently noted edema in persons with itch.

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION. W. A. PUCKNER, SECRETARY.

TYPHOID VACCINE (See N. N. R., 1918, p. 343).
The Gilliland Laboratories, Ambler, Pa.

Typhoid Vaccine.—Prepared according to the method of the U. S. Army Medical School Laboratory from the Rawling's strain. Marketed in packages containing three syringes, the first containing 500 million killed typhoid bacilli and the second and third containing each 1,000 million killed typhoid bacilli; in packages containing three ampules, the first containing 500 million killed typhoid bacilli and the second and third containing each 1,000 million killed typhoid bacilli; also in ampules containing from 5 to 100 Cc. of the vaccine as ordered.

VACCINE VIRUS (See N. N. R., 1918, p. 323).
The Gilliland Laboratories, Ambler, Pa.

Small-Pox Vaccine.—Marketed in sealed capillary tubes, in packages containing one, five and ten tubes each.

OLD TUBERCULIN (See N. N. R., 1918, p. 326).
The Gilliland Laboratories, Ambler, Pa.

Original Tuberculin, "O. T."—Marketed in 1 Cc. vials.

Tuberculin Ointment in Capsules (For the Moro Percutaneous Diagnostic Test).—An ointment consisting of tuberculin "Old" and anhydrous wool fat equal parts. Marketed in capsules sufficient for one test.

TUBERCULIN DENYS, B. F. (See N. N. R., 1918, p. 329).
The Gilliland Laboratories, Ambler, Pa.

Bouillon Filtrate Tuberculin, "B. F."—Marketed in 1 Cc. and 3 Cc. vials; preserved with 0.4 per cent trikresol.

NEW TUBERCULIN, B. E. (See N. N. R., 1918, p. 328).
The Gilliland Laboratories, Ambler, Pa.

Bacillen Emulsion Tuberculin, "B. E."—Marketed in 1 Cc. and 3 Cc. vials; preserved with 0.4 per cent. trikresol.

NEW TUBERCULIN, T. R. (See N. N. R., 1918, p. 328).
The Gilliland Laboratories, Ambler, Pa.

Tuberculin Residue, "T. R."—Marketed in 1 Cc. and 3 Cc. vials; preserved with 0.4 per cent. trikresol.

DETRE DIFFERENTIAL TEST (See N. N. R., 1918, p. 330).
The Gilliland Laboratories, Ambler, Pa.

Tuberculin for the Detre Differential Diagnostic Test.—Consisting of one tube each of Original Tuberculin "O. T.", Bouillon Filtrate Tuberculin "B. F." human, and Bouillon Filtrate Tuberculin "B. F." bovine.

CRESOL (See N. N. R., 1918, p. 91).
Cresol-Merck.—A brand of cresol, U. S. P.
Manufactured by Merck and Company, New York.

GUAIACOL CARBONATE (See N. N. R., 1918, p. 87).
Guaiacol Carbonate-Merck.—A brand of guaiacol carbonate, U. S. P.
Manufactured by Merck and Company, New York.

QUININE DIHYDROCHLORIDE (See N. N. R., 1918, p. 281).
Quinine Dihydrochloride-Merck.—A brand of quinine dihydrochloride, U. S. P.
Manufactured by Merck and Company, New York.

QUININE AND UREA HYDROCHLORIDE (See N. N. R., 1918, p. 282).
Quinine and Urea Hydrochloride-Merck.—A brand of quinine and urea hydrochloride, U. S. P.

THE CALL FOR MEDICAL OFFICERS

In The Journal two weeks ago appeared the announcement of Surgeon-General Gorgas to the American Medical Association of the need of five thousand additional officers for the Medical Reserve Corps. Last week The Journal contained the report of the War Committee of the Association outlining the initial steps in the campaign to secure these five thousand volunteers. Already a most encouraging lot of letters have been received from physicians asking for application blanks and for information relative to the service. Even before any systematic appeal has been made the medical profession is indicating that it stands ready to respond.

A number of physicians have stated their circumstances and have asked The Journal to aid them in making a decision as to whether it is their duty under such and such circumstances to volunteer. The physician who volunteers for the Medical Reserve Corps at this time does so under different circumstances than did the men who volunteered a year ago when our country entered the war. Constructive legislation in the intervening period has removed many of the difficulties which at that time confronted the physician who faced the question as to whether or not he could volunteer for service. Congress has since provided for the care of dependents, for insurance and compensation, for increased pay on foreign service, for commutation of quarters, heat and light, for a moratorium on debts and leases of officers in the service, and for reconstruction and reeducation of the disabled and injured. Army regulations now provide that officers may purchase equipment directly from the Quartermaster's Department. Physicians who entered the service over a year ago did so without the assurance that this new legislation conveys. They made greater sacrifices than are required now.

The physician who comes into the Medical Reserve Corps today has probably been confronted with circumstances which prevented him from volunteering earlier. Many have hesitated because of fear as to the care of their dependents, of the inadequacy of the salary of a medical officer, of provision for their dependents in case of unfortunate disaster to themselves. To these men the Medical Department of the Army can now say that there is no longer cause for such fears and doubts.

The medical profession of Great Britain, well-nigh exhausted by the drains on its services, it is confidently stated elsewhere, will volunteer quickly to fill new demands. The American medical profession will do no less nobly. THE TIME HAS COME FOR EVERY MEDICAL MAN UNDER 55 YEARS OF AGE, WHO IS PHYSICALLY QUALIFIED, TO CONSIDER SERIOUSLY FOR HIMSELF THE QUESTION OF HIS DUTY TO HIS GOVERNMENT.[1]

THE POSSIBILITIES OF COTTONSEED FLOUR AS FOOD

In the extremely active search for new foods which may help to augment the all too limited supply that confronts the nations now at war, attention has repeatedly been directed to cottonseed as a possible addition to the human dietary. The oil of cottonseed is by no means unknown in dietetics, and it is no exaggeration to say that the best grades of the refined product are thoroughly appreciated. Undoubtedly, cottonseed oil also enters, in hydrogenated and solidified form or in its original more liquid state, into some of the novelties that are coming under a variety of trade names to replace the longer known fats used in cookery. Cottonseed meal has been employed for a long time, as a product rich in protein, in animal feeding. Under the name of cottonseed flour a more refined product, probably representing ground and bolted meal, has been proposed and used to some extent in the foods of man.

Some of the advantages that might be expected from it have been emphasized by the experiments of Richardson and Green[2] and of Osborne and Mendel.[3] The protein constituents are of excellent quality in the sense that they yield all of the amino-acids essential for the nutrition of growth. Laboratory animals have been carried into a second generation on cottonseed products as their sole source of protein. Furthermore, like other seeds, that of the cotton plant has a liberal content of the water-soluble vitamin that is now recognized as so important to well being. Despite certain culinary difficulties which seem to be rated with different significance by various experts in the household arts, cottonseed flour has been used in preparing mixed breads and other bakery products. Perhaps the objections to its use in this respect are by no means insuperable, especially since all classes of our population are becoming more tolerant of dietary novelties that upset all household traditions.

---

[1] Circular of information and application blank will be sent by The Journal on request.

Chem., 1916, **25**, 307; Nutrition Investigations upon Cottonseed Meal, II, ibid., 1917, **30**, 243; Cottonseed Flour: Nutrition Investigations upon Cottonseed Meal, III, The Nature of Its Growth-Promoting Substance and a Study in Protein Minimum, ibid., 1917, **31**, 379.

[3] Osborne, T. B., and Mendel, L. B.: The Use of Cotton Seed as Food, Jour. Biol. Chem., 1917, **29**, 289.

There is, however, another aspect of this problem which demands earnest consideration before cottonseed products can be endorsed for the human dietary. It has long been known that the liberal use of cottonseed meal may be attended with what is called cottonseed injury or toxicity in agricultural practice. Every recent investigator of the subject admits that the feeding of the unaltered seeds brings detrimental results. Withers and Carruth,[4] of the North Carolina Agricultural Experiment Station, have associated the harmfulness of the seeds with the presence in them of a toxic substance, gossypol, which is present to the extent of about 0.6 per cent. It appears from the work of the various students of the problem that gossypol is easily oxidized to nontoxic derivatives. The explanation of the lessened toxicity of the usually fed meal or flour, in contrast with the original seeds, lies in the fact that the former products are prepared from the residues left after cottonseed oil has been extracted from the seeds. This process is accomplished with the aid of heat. Accordingly, cottonseed meal is much less toxic than raw cottonseed, owing mainly to the oxidation of gossypol during the cooking that is required in the technic of oil manufacture. The toxicity of cottonseed products varies, according to Withers and Carruth, with the conditions under which the raw seed is cooked.

It seems most unfortunate that a food product as highly digestible and nutritive as cottonseed flour should await greater usefulness because the conditions for rendering its use dietetically safe have not yet been adequately controlled. Until this is done, however, an element of danger inevitably attaches to any propaganda in favor of what ought to become a wholesome food. Gossypol can be extracted from cottonseed; it can be rendered inert by heat. Presumably the manufacturing processes and the cooking requisite for the preparation of edible products eliminate the objectionable features. However, until a flour of guaranteed and established freedom from harm is available under properly controlled auspices, the further development of what may be a useful food industry will be impeded. The difficulties presumably can be solved, and assuredly ought to be, in the interest alike of nutrition and of the industries.

THE PHYSICAL QUALITIES OF AVIATORS

In considering the special qualities which aviators should have, Surgeon H. Graeme Anderson of the Royal Navy Service and adviser to the British Air Medical Service[1] suggests that in eliminating the unfit — and man power is an ever increasing problem — special flying schools be instituted where border-line pupils could be instructed in flying under the attention of sympathetic instructors and with a medical officer, especially interested in aviation, carefully recording results. In an address before the Medical Society of London last month, he recapitulated, on the basis of an extensive experience, his view as to the necessary physical qualities of aviators. In addition to a sound constitution free from organic disease, a fairly strong physique, normal hearing, good muscle and equilibration sense, the matter of greatest importance is good eyesight, and next to vision is temperament. For this reason an aptitude for flying was found most common among those used to sport and leading an outdoor life. The yachtsmen and the horsemen made skilful pilots. Until recently, the Germans selected aviators from the cavalry. However, occasionally it has been found that the type with the most splendid physique and apparently unshakable courage was unable to learn to fly, whereas the weedy, pale type learned quickly and became first-rate flyers. Candidates for aviation always should be made to undergo a surgical, medical and a special sense examination, preferably by experts, and then the final selection should be made by an especially selected committee. The best age for flyers is about 24 years, including the period from 18 to 30. Flyers should not be under 5 feet, 2 inches, Anderson believes, as they would have difficulty in reaching the rudder bar or looking over the cockpit of the aeroplane. Any evidence of epilepsy, vertigo, migraine, persistent headache, lack of concentration and easily induced fatigue should disqualify. The significance of disabilities of the extremities should depend on the extent to which these interfere with power to work the controls and to use the machine gun. Most movements in controlling an aeroplane are performed below the level of the shoulder. Alcohol should be strictly forbidden among pupils at a flying school, and there seems little doubt that the action of alcohol is accentuated in the air. Untreated or imperfectly treated syphilis, and recent attacks of malaria should bar the candidate from service. It has also been the experience of Surgeon Anderson that malarial attacks are precipitated by the cold experienced in flying, although other physicians believe little emphasis should be laid on this point.

Of course, the special sense examinations are of primary importance. As we stated last week,[2] the experience in the Royal Navy as well as that of

[2] The Bárány Tests in the Examination of Aviators, editorial, The Journal A. M. A., April 13, 1918, p. 1096.

American medical officers leads to the view that the aviator should have unaided, normal vision in both eyes and in each eye separately, and also normal color vision. The examination of the organs of the head and neck should be stringent and special attention paid to the presence of clear airway in the nose, as there seems to be definite relation to discomfort in flying and the appearance of severe headache because of lack of sufficient breathing space. The Italian army pays marked attention to this point. Any candidate showing a perforation of the tympanic membrane or cicatrices should be rejected as these men would probably suffer from pain in the ear induced by the incessant noise of the engine and by pressure effects from changing height rapidly. Perfect hearing is very important, especially in starting the aeroplane from the ground in order that the words "contact" and "switch off" given by the mechanic following the swinging of the propeller may certainly be heard and accidents avoided. Surgeon Anderson would also test especially the reaction time with regard to vision, hearing and touch and the emotional reactions according to the tests elaborated by Dr. Nepper. In these tests the aviator has around his chest a pneumograph, in his left hand a trembler and around two fingers of his right hand a pneumatic "doigtier." These are all connected by rubber tubes to stylets writing on a revolving cylinder, and this records the respiratory rhythm, tremor and the peripheral vasomotor control. A revolver shot is fired or a flash-light set off behind the candidate. In the best type of pilot with good nerves, the effects recorded are of very short duration, while in unsuitable ones the respiratory rhythm remains increased for some time, and there is marked tremor and peripheral vasomotor constriction.

In the discussion, Surgeon R. C. Munday, Medical Administrator of the Air Force, approved practically all of Anderson's suggestions and pointed out the great importance of selecting the best men possible without excluding any qualified men. It was his belief that no candidate should be passed within two years of the last manifestation of active syphilis. He is strongly opposed to alcohol being consumed at an aerodrome until the flying is over for the day, and then only in limited quantities. Practically every one of the physicians and officers taking part in the discussion agreed that the factor of vision was of the greatest importance. Mr. Ernest Clark especially said that a simple test with a + glass was insufficient and that cycloplegics should be used.

In this country we have no shortage of man power. Our athletes and our students have come forward by hundreds and even by thousands to enlist in this most hazardous yet fascinating service. Yet we should not be blind to the fact that very special qualities are needed, and the material should be most carefully sorted with a view not only to selecting the most capable men, but also to selecting all the capable men.

THE STABILITY OF VITAMINS

There is a widespread impression that those as yet little understood, but apparently indispensable components of the diet popularly termed vitamins are easily destroyed by heat. Obviously the establishment of the truth in this respect is a matter of great importance. Most of the foods that enter the diet of man beyond the period of infancy are subjected to heat in cooking; and at present the practice of food preservation as a part of the conservation movement involves the application of heat. One need only recall the preparation of canned vegetables, tinned meats and milks, and the sterilization of milk by heating, to appreciate a further aspect of the problem.

The statements as to the instability of vitamins toward heat seem, to a large extent at least, to be an outcome of the widely held belief that heated milk is responsible for infantile scurvy, which, in turn, is conceived to be a deficiency disease. As we have pointed out in the past, the etiology of scorbutus is far from being definitely understood, and the bearing of the milk factor in the genesis of the symptoms is still open to new interpretations. The most promising method of ascertaining the truth would seem to consist in studying the effect of heat on sources of vitamin that can be tested in unmistakable ways. One of these is afforded by the ready production of experimental avian polyneuritis, the analogue of human beriberi, which is easily relieved by suitable vitamin products. The results and their proper interpretation are usually clear. In this way several American investigators have shown that the boiling temperature of water is by no means entirely destructive to the antineuritic vitamin, even though heating under pressure may be destructive in its effects.

At the Lister Institute in London, Chick and Hume[1] have renewed the study of the fate of vitamins on heating, employing the antineuritic properties of the wheat embryo and of yeast as test objects. They found that exposure of wheat embryo to a temperature of about 100 C. (212 F.) for two hours resulted in no significant loss in antineuritic "vitamin." If, therefore, it is included in the flour from which bread or biscuit is made, it can be relied on to retain its antineuritic properties after baking. At temperatures in the neighborhood of 120 C. (248 F.), however, there was a swift destruction of antineuritic properties. This fact has an important bearing where diets are largely composed of preserved and canned foods previously sterilized at temperatures above 100 C.

There is at present a pronounced difference of opinion as to the nature of scurvy. The classic experimental animal for the study of this condition has been the guinea-pig. Holst has found that it will develop the disease in acute form if kept on a diet of cereals with water or sterilized milk. McCollum and his associates are unwilling to admit that scurvy belongs to the deficiency diseases in the sense of being caused by a lack of vitamins in the diet. They associate it rather with the absence of suitable texture or bulk to the food so that the intestinal functions are not appropriately exercised. In the forms of scurvy familiar in human experience, fresh fruits and vegetables are believed to have a pronounced curative virtue. Obviously the facts can be adjusted to a variety of hypotheses. It may be assumed that the curative foods mentioned furnish needed vitamins or that they succeed by altering the alimentary functions in a beneficial way. In any event, Holst reported that the antiscorbutic power of certain fresh foods, notably cabbage, was slightly lessened after exposure to 100 C. for half an hour, but that the deterioration was appreciable after one hour; at from 110 to 120 C. (230 to 248 F.) the destruction was rapid and complete. If such evidence is accepted, it would seem as if neither the antineuritic vitamin nor the antiscorbutic property, whatever the latter may be, can be expected to survive in canned or sterilized foods that have been subjected to temperatures approaching the damaging limits mentioned.

---

[1] Chick, Harriette, and Hume, E. Margaret: The Effect of Exposure to Temperatures at or above 100 C. on the Substance (Vitamin) whose Deficiency in a Diet Causes Polyneuritis in Birds and *Beri-Beri* in Man, Proc. Roy. Soc., B., 1917, **90**, 60.

Chick and Hume,[2] who have studied the distribution among foods, especially those suitable for the rationing of armies, of the substances required for the prevention of beriberi and scurvy, respectively, have come to the conclusion, to quote their own words, that "the antiscorbutic vitamin is present in active living vegetable tissues. It is also present in animal tissue, to a much less degree. Fresh vegetables and fresh fruit juices are the most valuable sources of antiscorbutic vitamin that we possess. All the dried foodstuffs examined, including desiccated vegetables, were more or less deficient in this vitamin." These investigators at the Lister Institute in London have further stated that dry legumes and cereals, though rich in antiberiberi vitamin, are deficient in antiscorbutic vitamin, and afford no protection against scurvy. If these are moistened, however, and allowed to germinate, the antiscorbutic principle is regenerated with the beginnings of active cell life. In view of their own experiments and the existing literature on the subject, Chick and Hume believe that in the case of armies or other populations subsisting largely on canned food, it is imperative to provide an adequate supply of vitamin from outside sources. Their dicta are: To prevent beriberi, the bread or biscuit should be made from whole-meal or germ-containing flour. To prevent scurvy, if a supply of fresh fruit or vegetables is not procurable, germinated legumes should be added to the diet.

We may admit the wisdom of giving due consideration to this carefully planned advice without thereby accepting the hypotheses that have been injected into it. It would be folly, we believe, to proclaim any wholesale condemnation of foods preserved with heat as devoid of antiscorbutic properties until far more evidence is available — evidence obtained without the prejudice of a preconceived theory of etiology. The propaganda for conservation of food by drying must not receive a setback until more conclusive proof of an actual deficiency of any vitamins that they may originally have contained is furnished. Nor must the interesting and valuable vitamin theory be allowed to overshadow completely the fact that calories are necessary for nutrition.

RETROGRESSION IN NEW YORK CITY

Preceded by a "private enquiry," there are now being held public hearings in New York City on the proposal to abolish the various bureaus of the Health Department of the City of New York. The excuse that is said to have been given by Mayor Hylan for this proposal is the excuse common to politicians — cutting down expenses! It would be just as rational to attempt to cut down expense by abolishing the street cleaning department and by discharging half the firemen and policemen in the metropolitan district.

The mayor's contention seems to be that as the city charter — of a half century ago — only specifies by name two bureaus in the Department of Health, the present subdivision into nine bureaus is illegal and should be abolished. This, too, in spite of the fact that the law department of New York City has, on more than one occasion, rendered opinions that the present system conforms with the law.

As now constituted, the directors of the nine bureaus in the Department are under the Civil Service law and cannot be discharged by the major unless incompetence or insubordination is definitely proved. Abolishing the bureaus will, of course, abolish the directors. There will then, apparently, be nothing to prevent the mayor from appointing his own "chiefs" to carry on the work of the Health Department.

Such a reorganization would not only give to the new administration a great opportunity for the distribution of political patronage; it would also make it possible to put in the place of those now acting as directors of the various bureaus individuals who would be more solicitous of various big businesses whose activities are opposed to public health. It may be assumed that under a political organization there would be no Bureau of Public Health Education, such as that now headed by Dr. Charles F. Bolduan. This bureau, one of the most important in the Department, has been unremitting in its efforts to give the New York public information regarding the nostrum evil and quackery. Needless to say, it has aroused tremendous opposition on the part of the quacks and nostrum venders. While it is probable that not even a Tammanyized administration would dare to abolish altogether the work now done by the Bureau of Food and Drugs under the direction of Lucius P. Brown, it is conceivable that a man could be put in charge of such work who might be counted on to be not too harsh with those who fatten on the sale and manufacture of sophisticated food and drugs. Possibly some of the other bureaus have, in the execution of their duty, offended powerful interests.

---

[2] Chick, Harriette, and Hume, C. Margaret: The Distribution among Foodstuffs (Especially Those Suitable for the Rationing of Armies) of the Substances Required for the Prevention of (A) Beriberi and (B) Scurvy, Tr. Soc. Trop. Med. and Hyg., 1917, **10**, 141.

There never existed a public health organization worthy of the name that did not bring down on its head the maledictions of those with whose activities it interferes. Whether the war against these various departmental agencies is being prompted by those who have been hurt by the Health Department's activities or whether it represents typical municipal partizan politics makes little difference; the result, if successful, will be the same. It is to be hoped that the best elements of the City of New York will get together and prevent the present highly efficient health administration of New York City being disorganized and put back into a régime that has been abolished by every progressive city in the United States.

Current Comment

COMMUTATION OF QUARTERS FOR OFFICERS

The President has signed the bill for commutation of quarters. The bill provides that "during the present emergency every commissioned officer of the Army of the United States on duty in the field, or on active duty without the territorial jurisdiction of the United States, who maintains a place of abode for a wife, child or dependent parent, shall be furnished at the place where he *maintains* such place of abode, without regard to personal quarters furnished him elsewhere, the number of rooms prescribed by the Act of March 2, 1907, to be occupied by, and only so long as occupied by, said wife, child or dependent parent; and in case such quarters are not available every such commissioned officer shall be paid commutation thereof, and commutation of heat and light, at the rate authorized by law in cases where public quarters are not available; but nothing in this Act shall be so construed as to reduce the allowances now authorized by law for any person in the Army." This most important legislation is destined to relieve much real distress. Like much other legislation, the verbiage of the law is doubtful on some points and the comptroller has been asked to issue rulings and interpretation of the new legislation for the guidance of disbursing officers. The law was passed in order that officers who are compelled to maintain a residence for their dependents may receive commutation to help meet this drain on their resources. The question has arisen as to whether officers on duty abroad, who are provided with commutation of quarters, heat and light, for instance, in France, will also receive allowance for a family in this country. According to the *Army and Navy Register*, "It is hoped that the comptroller will decide that an officer may draw double commutation of quarters for the full number of rooms allowed for his grade with commutation of heat and light, for the number of rooms actually occupied abroad by himself, and the number of rooms actually occupied by the members of his family at home." Another question concerns the interpretation of the words "wife, child and dependent parent," and it is suggested that the latter term includes father, mother, grandfather, grandmother, step-father, step-mother, either of the officer or of his wife. For those physicians who do not understand the interpretation of the term "commutation of quarters," we may say that a commissioned officer on duty at a place at which no public quarters are available — such as an Army post — is entitled to commutation of quarters, which amount is added to the pay of the officer by the paymaster each month. The officer is also entitled to commutation for fuel and light, which is also entered on his voucher according to tables published in Army Regulations. The commutation consists of $36 for first lieutenant, $48 for captain and $60 for major. As will also be seen from the text of the law, this commutation of quarters is not paid to unmarried officers unless they maintain a home for a dependent parent.

ABSORPTION THROUGH UNUSUAL SURFACES

The question as to the possibilities of absorption through the exterior surfaces of the body has often been raised, particularly with respect to the permeability of the skin and some of the mucous membranes to drugs and to poisons that might reach these parts of the organism accidentally in industrial processes. It is quite generally regarded as established that the sound skin is impermeable for watery solutions of salts and other substances. Where the integument has been injured by a blister, or its surface has been denuded in some way, the exposed tissue may possibly offer an avenue of entrance for soluble products. This is not, however, a true cutaneous absorption. The possibility of absorption by inunction of substances dissolved in fats or fatlike compounds cannot be denied. It has been emphasized anew by studies, recently reported in The Journal, on the behavior of mercury applied in this way.[1] But as a well known physiologist remarked in a recent textbook, it is difficult to imagine that any appreciable amount of cod liver oil will be available for the nutrition of an infant when this fat is administered by being rubbed on the skin. That moist mucous surfaces, like the conjunctiva, permit of the transport of drugs through them is generally assumed in the daily practice of introducing substances into the conjunctival sac in ophthalmologic routine. D. I. Macht,[2] of the Johns Hopkins laboratories, has demonstrated that in such cases the absorption is due, in part at least, to direct entry into blood and lymph channels, and is not solely the result of an indirect absorption through the nasal ducts. For even when the latter were completely obstructed, sufficient apomorphin to produce vomiting could still be absorbed from the eye into the general system. As apomorphin produces its emetic action by direct stimulation of the vomiting center, the use of this drug in the study of the permeability of unusual surfaces excludes any confusion with reflex effects set up by local irritation. Apomorphin itself must permeate to the blood stream before it can unfold its specific activities. Macht has therefore employed it to demonstrate absorption through the vaginal wall, the urethra, the prepuce, the nasal canal and other structures. In many of these instances the suspicions of experience are supported by the demonstrations of the controlled experiment.

THE SUPREME COURT DECISION ON THE CORPORATE RIGHTS OF THE AMERICAN MEDICAL ASSOCIATION

In 1910 the state's attorney of Cook County (Chicago) was petitioned to institute "quo warranto" proceedings against the American Medical Association on the grounds that the Association's affairs were being conducted illegally in that its officers were elected at annual sessions held outside of the state of Illinois. The state's attorney refused to take action in the matter, and later, the attorney general of the state, who was appealed to, also refused to act. January 5, 1911, mandamus proceedings were begun in the Circuit Court of Cook County, Illinois, to compel the state's attorney to initiate the quo warranto action which he had declined to institute. Until December 20, 1915, the issue was between the parties asking for the "mandamus" and the state's attorney of Cook County, Illinois; the point at issue being the technical one as to whether the state's attorney was compelled to act or had discretionary authority in the matter. The case went through the lower courts and finally was carried to the Supreme Court of Illinois, which in December, 1915, refused to hear arguments on the merits of the cause as it related to the American Medical Association, but ordered the Circuit Court to take up the original quo warranto proceedings designed to raise the question of whether or not Illinois corporations "not for profit" are compelled to hold their elections and conduct their business within the confines of the state. Up to this point the American Medical Association was not technically interested in the controversy; now, however, it became a party in the action. Quo warranto proceedings against the members of the Board of Trustees were instituted in the Circuit Court of Cook County, Illinois, which after trial rendered a decision favorable to the Association. The case was then carried to the Appellate Court of Illinois, which confirmed the decision of the Circuit Court. An appeal was finally made to the Supreme Court of Illinois, which last week (April 16) rendered its decision, settling the question. This decision is entirely satisfactory so far as the Association is concerned. One paragraph of the opinion reads:

> It seems reasonably to follow that if a corporation not organized for pecuniary profit may hold meetings at stated times outside of the State of Illinois, composed of delegates selected by the constituent associations, for the transaction of business of the corporation, it is not unlawful to authorize and provide for the election by said house of delegates of trustees of the corporation. The American Medical Association was organized solely for the purpose of the advancement of medical science. Its purpose was to improve methods for the treatment and prevention of diseases of the human race. Its usefulness for these purposes would be seriously interfered with, if not absolutely destroyed, if it could not provide for the election of trustees from the most efficient men in the association throughout the United States, by delegates selected by the constituent associations from the various States in the Union. Such authority to the house of delegates is conferred by the by-laws and is not in conflict with or prohibited by the constitution or laws of Illinois relating to corporations not for pecuniary profit.

The decision is important not only to the American Medical Association, but also to all organizations incorporated under the law of Illinois — in fact of any state — governing corporations "not for profit."

ANOTHER APPEAL TO THE BRITISH MEDICAL PROFESSION

The *British Medical Journal* for March 30 presents a rather gloomy survey of the situation so far as concerns the Medical Department of the British Army. Even before the drive of the last four weeks, the ranks of the civilian medical profession had been pretty well drained. Our contemporary practically acknowledges that 45,000 prisoners were taken, and that in this total must be included a large number of medical officers. In addition, it is quite probable that many medical men were killed or seriously wounded. "The emergency is so great," it says, "that the Ministry of National Service makes an urgent appeal to members of the medical profession to come forward with offers of voluntary service to meet the existing pressure. The appeal is made — First, to medical men now in this country who have relinquished their commissions and have not rejoined. Their services are immediately and urgently required with the armies in France. Secondly, an appeal is made to medical men under the age of 55 who are physically fit to offer their services either at home or abroad." It goes on to say that the number of men in these categories that can be available is small, and that in many areas the number of civilian practitioners has been reduced to a level which has caused anxiety to the civil authorities. "But the situation which has to be faced is serious, and we are confident that the voluntary spirit of medical men will face it. Every one of them who responds immediately will be performing an act of practical patriotism as well as of individual fortitude."

Medical Mobilization and the War

Personnel of the Medical Department

For the week ending April 19, 1918, the personnel of the Medical Department of the Army included:

Medical Corps: 843, including 1 major-general, 66 colonels, 102 lieutenant-colonels, 195 majors, 2 captains and 477 lieutenants.

Medical Reserve Corps: 18,651, including 1,194 majors, 4.418 captains and 13,039 lieutenants. On active duty: 16,042, including 1,063 majors, 3,949 captains and 11,030 lieutenants.

Medical Corps, National Guard: 1,207, including 16 lieutenant-colonels, 249 majors, 150 captains and 792 lieutenants.

Medical Corps, National Army: 111, including 3 brigadier-generals, 11 colonels, 89 lieutenant-colonels and 8 majors.

Dental Corps, 209; Dental Reserve Corps, 5,207; of whom 1,357 are on active duty; Dental Corps, N. G., 259; Veterinary Corps, 18; Veterinary Reserve Corps, 1,432, of whom 823 are on active duty; Veterinary Corps, N. G., 51; Veterinary Corps, N. A., 374; Sanitary Corps, 1,028, and Ambulance Service, 154, constitute the remainder of the commissioned personnel.

The Discharges in all branches of the service to date are:

	Number			
Causes	M.R.C.	M.C.N.G.	D.C.N.G.	San.C.

American Medical Officers Under Fire

Press dispatches call particular attention to the actions of American physicians and nurses in the midst of the great drive now taking place on the Western battle front. They reveal that the medical officers conducted themselves with exceptional bravery and coolness while under fire. As the Germans advanced it became necessary for casualty clearing stations and field hospitals to retire. How difficult a task this was may well be conceived by any one with a knowledge of what it means to transport thousands of wounded and tons of equipment while under fire and along roads jammed with the tremendous paraphernalia of the fighting army. It is reported that when the offensive opened the British had large advance stations which came under immediate pressure. While shells and bombs rained on the hospitals, the physicians and nurses continued to attend the wounded, to pack supplies and to arrange for transportation. The severely wounded were carried back in ambulances, but every man able to walk was forced to transport himself back to his new station. It is reported that the more valuable surgical instruments and supplies were taken in charge by physicians who in many cases personally piled them on wheeled stretchers and pushed them for long distances.

Social Hygiene Division

The War and Navy Departments Commissions on Training Camp Activities have formed a social hygiene division under the head of Major William F. Snow of the Surgeon-General's Office. The work of the division will be entirely educational, and will be divided into three sections with Dr. Katherine B. Davis, William H. Zinsser and Lieut. Walter Clarke as directors. Lieutenant Clarke will continue the educational work that he has been doing in the cantonments with the full cooperation of the War Department and with a large staff of lecturers on social hygiene. The lectures are compulsory with the men in the camps, and exhibits and literature are used in connection with them. The section on men's work under the direction of William H. Zinsser will concern itself with the education of men in civilian communities. This work was formerly under the direction of the Council of National Defense, but is now transferred to the social hygiene division under the Commission on Training Camp Activities. Dr. Katherine B. Davis will direct the section on the education of women and girls. A lecture bureau will be maintained in cooperation with the social morality committee of the war work council of the National Y. W. C. A., the American Social Hygiene Association and similar organizations, which have also previously cooperated with the other sections named. This bureau will supply lecturers to groups of women and girls and will work in industrial communities as well as in communities adjacent to camps.

Reconstruction and Reeducation of Disabled Soldiers

The Department of Reconstruction and Reeducation of the Surgeon-General's Office has just issued Bulletin No. 3 of its series on this subject, consisting of abstracts, translations and reviews of the recent literature on reconstruction and reeducation of the disabled soldier. The present bulletin, dated April 15, consists of 112 pages, and is Part One of a series to be entitled "The Story of a Crippled Soldier's Progress from Disablement to Placement in Civil Life." It describes the experiences of Great Britain and France. In Bulletin No. 4 it is intended to supplement the history by describing the same evolution in Canada, Italy, Belgium, Austria, Germany, and perhaps in other belligerent countries.

British Military Cross Awarded to American Medical Officer

It is reported that Lieut. Theodore Higgins Sweetser, M. R. C., has been recommended for the British Military Cross for conspicuous gallantry and devotion to duty. The recommendation reads:

> He gave valuable assistance to more than forty men suffering from gas, while he, himself, also was suffering from the effects. His two noncommissioned officers had succumbed. He also rendered valuable assistance to a party of tunnelers, the entrance of whose dugout had been struck by a gas shell, waking the men and forcing the tubes of their respirators into their mouths and clips into their noses. But for his prompt attention, a large number of men would have succumbed.

In a letter to Lieutenant Sweetser, General Pershing is reported to have said:

> The commander-in-chief desires me to say that he appreciates the splendid conduct shown by you on this occasion.

Control of Venereal Diseases in Massachusetts

The Massachusetts State Department of Health has declared gonorrhea and syphilis "diseases dangerous to public health" and reportable directly to the state department of health. The department feels that the system of venereal disease reporting possessing the greatest potential benefit to the public health and the least objectionable features from the standpoint of the patient and the physician should combine the following features: 1. It should have a definite educational value. 2. It should impress the patient with the seriousness of the disease. 3. It should make the patient understand the possibilities for harm to others because of its infective nature. 4. It should impress on the patient the need of proper medical guidance. 5. It should, as far as it is consistent with the best interests of the public health, respect the patient's instinctive desire for secrecy.

All regulations, reports and circulars have been prepared with these principles in view. The name of the patient becomes reportable only when he will not follow proper medical advice or cease from infecting others. The identity of the reporting physician is not even revealed.

The Massachusetts venereal disease program may be separated into four general divisions: (1) venereal disease reporting; (2) the problem of extension of facilities for diagnosis and early treatment; (3) repressive measures, and (4) educational measures.

The so-called "West Australian" method of reporting is adopted. At the time of the first visit or consultation the physician furnishes the patient with a numbered circular of information and advice. At the same time he fills out the numbered report blank attached to the circular of advice and mails it to the state department of health. If the patient has been under the care of another physician previously, the second physician consulted notifies the first one on a special blank provided for that purpose. If the patient fails to return to the attending physician for a period of six weeks, the physician notifies the state department, which, in turn, notifies the local board of health of the community in which the patient resides.

Adequate provision has also been made for measures of diagnosis and treatment. Laboratory diagnostic facilities are now pretty generally available throughout Massachusetts. Smears are examined and Wassermann tests are made free. The state department contemplates the establishment of some fifteen "state-approved" clinics to be situated in the center of a district. A "chief" is to be in charge of this clinic to act as agent for the state department in the distribution of arsphenamin. The objects will be thorough diagnosis, better treatment, modern follow-up work, and closer cooperation with the practicing physician.

Under the heading "repressive measures" are grouped a number of antivenereal measures that involve the joint utilization of police power and social agencies. The principal repressive measures contemplated are: (1) suppression of prostitution; (2) venereal control in the penal population; (3) the venereal quack problem, and (4) indirect control through the license power of the state. Legislation has been introduced prohibiting the druggists from prescribing for venereal diseases and prohibiting the sale of venereal remedies except on a physician's prescription.

The most characteristic features of this new program against prostitution are the emphasis placed on prostitution as an epidemiologic rather than as a penal problem, and treating the individual prostitute as a disease carrier instead of officially ignoring her existence. Legislation has been introduced requiring thorough physical examinations of all inmates of penal institutions. A statutory provision exists now under which a prisoner infected with syphilis may be restrained beyond his term of commitment for the purpose of treatment. It is believed, confidently, that with the establishment of free or low-pay clinics throughout the state, where the highest quality of scientific treatment for venereal diseases is made accessible for every one, there will vanish the last excuse for the existence of the advertising venereal quack. The control of license power contemplates control through medical license power, druggist license power, liquor license power and marriage license power.

Educational measures look rather toward the future. The success of all other measures will be greatly increased by the active support of public opinion, founded on knowledge of the facts. The plans worked out for the reporting of the disease are educational. The proposed clinics will serve as educational centers where information may be secured and where approved forms of treatment may be demonstrated. Small framed placards giving information will be posted in public toilets and other suitable places. Pamphlets, lectures, and the instruction of college and normal students will also be means for spreading educational propaganda and knowledge regarding these diseases, and all these, it is believed, will eventually lead to the conduct of a campaign against venereal diseases in newspapers and magazines on the same plane as the discussion of fire dangers, accidents in industry, or any other serious problem that threatens the public welfare.

IN OTHER STATES

Iowa declared venereal diseases reportable in 1913, and also prescribed a penalty for the transmission of these diseases.

In California, syphilis and gonorrhea were made reportable diseases, beginning Jan. 1, 1911.

Feb. 20, 1918, the Tennessee State Board of Health issued an order requiring all county and municipal boards of health to report cases of gonorrhea and syphilis regularly on the first day of every month.

Other states in which similar rules are now effective are Ohio, Illinois, New Jersey, Minnesota, Pennsylvania and North Carolina.

Cities also have passed legislation requiring the reporting of venereal diseases. Chicago passed an ordinance, June 29, 1917. The sanitary code of 1915 of New York City provides for reporting venereal diseases. The department of health maintains that all facilities for the diagnosis of infectious preventable diseases properly fall within its province, and conforming thereto it has provided every available means for the ready diagnosis of these diseases, free of cost. It also performs the Wassermann test and the complement fixation test for gonorrhea, examines smears for gonococci and spirochetes, and makes cultural examinations of urinary sediments and urethral discharges.

Part of the New York educational campaign consists in combating quackery by enforcing the regulations of the board of regents and the board of aldermen, and by an effort to divert prospective victims from the quacks through newspaper advertising and the posting of venereal disease signs in suitable locations. Circulars of information and instruction are issued for distribution among patients.

Denver has just joined in the fight against venereal diseases by adopting an ordinance "to protect the public health and to prevent and restrain venereal diseases in the city and county of Denver." Syphilis, gonorrhea and chancroid are declared to be contagious, communicable and infectious diseases and dangerous to the public health, and subject to quarantine and isolation when deemed a menace. Physicians and druggists must report these diseases whenever they have knowledge of a case. This also applies to hospitals and other institutions. Unfortunately Denver did nothing with reference to advertisements of antivenereal remedies in the newspapers.

DISEASE CONDITIONS AMONG TROOPS IN THE UNITED STATES

From Telegraphic Reports Received in the Office of the Surgeon-General for the Week Ending April 12, 1918

1. ANNUAL ADMISSION RATE PER 1,000 (DISEASE ONLY):	
All Troops	1,627.1
National Guard Camps	1,232.2
National Army Camps	1,959.4
Regular Army	1,502.5
2. NONEFFECTIVE RATE PER 1,000 ON DAY OF REPORT:	
All Troops	48.
National Guard Camps	27.8
National Army Camps	55.7
Regular Army	44.8
3. ANNUAL DEATH RATE PER 1,000 (DISEASE ONLY):	
All Troops	11.3
National Guard Camps	3.4
National Army Camps	17.9
Regular Army	10.3

NEWS OF THE CANTONMENTS

Thirty-First Division, Camp Wheeler, Macon, Ga.

April 19, 1918.

NEW EPIDEMIC

An epidemic of influenza now prevails in the camp with about 500 cases. It appears that one epidemic follows another like the seven plagues of Egypt. Influenza is not a serious disease, the attacks lasting only a few days; but it swells the sick report, and recalls previous visitations of mumps, measles and pneumonia. One always wonders what is coming next.

A detachment of 200 negroes that recently arrived at the camp, now has mumps to the extent of forty cases. No attempt is made to prevent the spread of this disease.

SANITARY WORK

The extensive swamps in and around Camp Wheeler are being cleared and drained. Those inside are being done by the camp authorities, those outside by the Public Health Service. Captain Green of the Sanitary Corps is making a survey of the inner area and laying out the ditching work. The continued cold weather has prevented any extensive mosquito breeding up to the present time, even had there been no antimosquito work.

Latrine boxes and screens are being repaired in anticipation of the fly season. The present warm weather will hasten their arrival.

PERSONAL

Lieutenant-Colonel McCormack, who has been inspecting the sanitary train, accompanied the division on the recent march.——Major Gaylord, M. C., of Buffalo, has recently arrived from Allentown, Pa., for duty as assistant to the camp surgeon.——Lieutenant-Colonel Duncan has brought his family to Macon, where they will remain until the division leaves for France.——Lieutenant-Colonel Turck has gone to Camp Doniphan, Fort Sill, Okla., for duty as division surgeon of the Thirty-Fifth Division.——Lieutenant-Colonel McCormack is leaving for Camp Lee, after an instructive inspection of the One Hundred and Sixth Sanitary Train.——Major Harrold, One Hundred and Twenty-First Infantry, and Major Taylor, One Hundred and Eighteenth Artillery, attended the medical meeting at Savannah.——A lieutenant of the Medical Reserve Corps is being tried for charging enlisted men for medical services. A dental surgeon was recently convicted on a similar charge.

PRACTICE MARCH

The Thirty-first Division made a five days' march during the last week. The sanitary train was an important part of the column. The whole train marched, although there was transportation for but three ambulance companies and one field hospital. The mule ambulance companies furnished ambulances for the regiments on the march, with one motor company in the rear of the column, for the overflow, it having been demonstrated that motor ambulances cannot be mixed in a column of infantry. Another motor company acted as an evacuation column, carrying patients from the field hospital to the base hospital at Camp Wheeler. About 300 patients were thus evacuated. Sick call was held in the afternoon, and the evacuation carried out in the evening or at night. All ambulances were ready to start clear each morning. It was the general opinion that the sanitary train functioned well; no complaint of neglect was heard. The excessive number of patients was due to the prevailing influenza epidemic.

Lincoln Division (Eighty-Fourth), Camp Zachary Taylor, Louisville, Ky.

April 22, 1918.

LINCOLN DIVISION

The official seal and insignia of the Eighty-Fourth Division at Camp Zachary Taylor has been definitely adopted. It has been approved by the commander Major-General Hale, and will be put into use at once. In designing the emblem the idea of carrying out the name of Lincoln was adhered to. The center of the insignia is a woodchopper's ax, symbolical of the "Railsplitter." Above appears the name of the martyred President and below the number of the division. The national colors are included in the scheme. The circles and head of the ax are red, the lettering and the ax handle blue and the field is white.

PHYSICAL TESTS

The physical tests of medical officers of the camp have begun under the direction of Lieut.-Col. Luther R. Poust, acting camp surgeon. Every afternoon scores of medical officers are ordered to report to the drill field like ordinary soldiers. They are put through the school of the soldier. Many of the officers have never drilled before and plainly show the effects of the three-hours' work. The movement is only to show to the satisfaction of their superior officers that they are fit physically to stand the rigors of the war in France. It is understood that those medical officers who fail to qualify physically for foreign service will not be discharged, but will be left in the army camps of the United States to train the coming new drafted men. Within a few weeks they will be taken on 30-mile rides each day and put through other tests which, when completed, will leave only those medical officers who are fit for foreign service.

SURGICAL OPERATIONS

Men drafted into the National Army who have physical defects that may be remedied by surgical operations and who refuse to submit to the surgeon's knife will be courtmartialed under the Ninety-Sixth Article of War, and are subject to such punishment as the court may direct. This action is set forth in General Orders 167 of the War Department. The first case to arise at Camp Zachary Taylor of an enlisted man refusing to submit to a surgical operation has resulted in Major-Gen. Harry C. Hale, commander of the Eighty-Fourth (Lincoln) Division, appointing a board of medical officers to examine a private [illegible]'s Corps, Auxiliary Remount Depot No. 319, to determine if a surgical operation in his case is thought necessary to render him physically fit for service. The members of the board are Lieut.-Col. W. L. Pyles, Major J. H. McHenry, and Capt. Phillip Lewin. The examination will be conducted at the base hospital. Should the officers deem the operation necessary and the man still refuse to submit he will be liable to courtmartial proceedings. Since the opening of the cantonment a number of selects have been found to have ruptures or other ailments which interfered with their activities and duties as soldiers, but which were remedied by operations. Heretofore no complications arose over such situations, as the men willingly agreed to have their defects remedied.

PROPHYLACTIC ORDERS

A circular memorandum, issued from the office of the General Staff, advises every officer and man thus:

> In this section of the country much of the war weather sickness is due to diseases transmitted by mosquitoes and flies. The mosquito and fly are both rapid breeders, and the destruction of one mosquito or fly at this time of the year is the prevention of millions by fall.
>
> The following measures will be put into effect at once: Dense vegetation and underbrush will be cleared from the area pertaining to the unit. Mosquito bars will be drawn and held for use. Ditches will be cleared; areas impossible of drainage will be oiled with crude oil; water in fire buckets will be changed weekly.

Besides many other pointers given the command attention is called to fly traps: "requisition will be made for fly traps, and as soon as they are issued they will be used as follows: The large type will be kept just outside the kitchen and mess hall doors, at each table, picket line and corral, at each veterinary hospital, garbage, transfer station, and at other places where flies congregate in large numbers. The small type will be kept inside kitchens, mess halls, bakeries and infirmaries. Fly traps will be baited with molasses and vinegar, sugar, fish or any of the usually good baits. Raw fish is especially attractive to flies."

WHAT "TOTAL DISABILITY" IS

An interesting decision has arrived from the Bureau of War Risk Insurance as to what constitutes "total disability."

It says: "Any impairment of mind or body which renders it impossible for the disabled soldier to follow continuously any substantially gainful occupation shall be deemed to be total disability."

"Total disability shall be deemed to be permanent whenever it is founded on conditions which render it reasonably certain that it will continue throughout the life of the persons suffering from it. Whenever it shall be established that any person to whom any instalment of insurance has been paid as provided in Article 4 on the ground that the insured has become totally and permanently disabled, has recovered the ability to continuously follow any substantially gainful occupation the payments of installments of insurance shall be discontinued forthwith, and no further installments thereof shall be paid so long as such recovered ability shall continue."

PERSONAL

Dr. William O'Neil Sherman of Pittsburgh, who recently spent six months in France visiting the various war hospitals, paid the Three Hundred and Ninth Sanitary Train a visit and entertained and instructed all officers of the organization with a lecture on the treatment of burns and on Carrel-Dakin's treatment of infected wounds—Lieut.-Col. Luther R. Poust, assistant to the division surgeon, Lieut.-Col. John H. Allen, was granted an eight-day leave to go to the bedside of his mother, who is seriously ill at her home at Muncie, Pa.——Major Paul Fletcher has been relieved from duty with the Three Hundred and Ninth Sanitary Train at his own request, and will be assigned to the Medical Corps of the Three Hundred and Twenty-Fifth Field Artillery. He is succeeded by Major Bauker, who will be the director of the ambulance companies.

ORDERS TO OFFICERS OF THE MEDICAL CORPS AND OF THE MEDICAL CORPS OF THE NATIONAL ARMY

To Birmingham, Ala., and *Savannah, Ga.,* for duty, and on completion *to his proper station,* Col. CLAUD K. MORGAN.

To Camp Colt, Gettysburg, Pa., *Aviation Supply Depot,* Middleton, Pa., and *Camp Crane,* Allentown, Pa., for sanitary inspection, and on completion *to his proper station,* Lieut.-Col. FRANK W. WEED.

To Camp Crane, Allentown, Pa., for duty, from Fort Oglethorpe, Lieut.-Col. JAMES F. HALL; from Camp Fremont, Lieut. FRANCIS M. FITTS.

To Camp Dix, Wrightstown, N. J., for duty, from New York City, Lieut. EGBERT H. WESSON.

To Camp Greene, Charlotte, N. C., for duty, from Camp Greene, Lieut. HAROLD E. CLARK.

To Camp Logan, Houston, Tex., for duty, from Camp Logan, Lieut. RICHARD S. MAGEE.

To Camp Sevier, Greenville, S. C., base hospital, from Camp Sevier, Lieut. ROBERT S. McGEACHY.

To Camp Sherman, Chillicothe, Ohio, *Camp Custer,* Battle Creek, Mich., and *Camp Meade,* Annapolis Junction, Md., for inspection, and on completion *to his proper station,* Lieut.-Col. WALTER E. PARKER.

To Camp Zachary Taylor, Louisville, Ky., for duty, from Camp Zachary Taylor, Lieut.-Cols. JOHN H. ALLEN, WILLIAM M. SMART.

To Curtis Bay, Md., for sanitary inspection, and on completion *to his proper station,* Col. WESTON P. CHAMBERLIN.

To Fort McPherson, Ga., for inspection, and on completion *to Fort Oglethorpe* for inspection, and on completion *to their proper stations,* Major-Gen. WILLIAM C. GORGAS; Col. EDWARD L. MUNSON.

To Fort Oglethorpe for inspection, and on completion *to Camp Jackson,* Columbia, S. C., for duty, and on completion *to his proper station,* Col. GEORGE E. BUSHNELL. For instruction, from Camp Beauregard, Capt. HORACE E. RUFF.

To Fort Sam Houston, Tex., as commanding officer of base hospital, from Douglas, Ariz., Major FREDERICK C. A. KELLAM.

To Hoboken, N. J., for special duty, and on completion *to Washington, D. C.,* Col. CHARLES LYNCH.

To New Haven, Conn., for inspection, and on completion *to his proper station,* Col. GEORGE E. BUSHNELL.

To Newport News, Va., for investigation, and on completion *to their proper stations,* Col. FREDERICK F. RUSSELL, Lieut.-Col. WARFIELD T. LONGCOPE. For examining tuberculosis cases, and on completion *to his proper station,* Lieut.-Col. EARL H. BRUNS.

To New York City for duty, and on completion *to his proper station,* Lieut.-Col. EDGAR KING.

To Philadelphia, Pa., for orthopedic instruction, and on completion *to Hoboken, N. J.,* for temporary duty, from Camp Logan, Lieut. NORMAN ZOLLS.

To report in person to the commanding general, Southern Department, for duty, from Fort Sam Houston, Major JOHN T. AYDELOTTE.

To San Diego, Calif., Signal Corps Aviation School, for duty, from Seattle, Lieut. GEORGE W. BEELER.

To Southern Field, Americus, Ga., *Camp Joseph E. Johnston,* Jacksonville, Fla., *Dorr Field,* and *Carlstrum Field,* Arcadia, Fla., *Fort Screven,* Ga., and *Charleston, S. C.,* for sanitary inspection, and on completion *to his proper station,* Sr.-Surgeon JOSEPH H. WHITE.

To U. S. Army General Hospital, New Haven, Conn., *Watervliet Arsenal, N. Y., Disciplinary Barracks,* Fort Jay, N. Y., *U. S. Army General Hospital,* Williamsbridge, N. J., *Picatini Arsenal, N. Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest; such as relate to society activities, *new hospitals, education*, public health, etc.)

ALABAMA

Miscellaneous.—At the meeting of the board of trustees of Howard College, March 13, the proposition of the United States government to establish a reconstruction hospital at Birmingham, using the grounds and buildings of the college for the purpose, was endorsed.——A health survey in Madison County was begun at Huntsville, March 14, under the direction of Dr. Carl A. Grote, county health officer.——Sanitation in the vicinity of Muscle Shoals, where government ammunition plants are to be erected, was begun March 15. Dr. Harry S. Mustard of the Public Health Service has been placed in charge of the work.

Officers Elected.—At the meeting of the Medical Association of the State of Alabama, held in Birmingham from April 16 to 19, the following officers were elected: president, I. L. Watkins, Montgomery; vice president, H. S. Ward, Birmingham (northern division); secretary, H. G. Perry, Montgomery; treasurer, J. U. Ray, Woodstock; censors for five years, Glenn Andrews, Montgomery, and S. G. Gay, Selma; censor for four years, C. A. Thigpen, Montgomery, to fill unexpired term of Dr. W. H. Sanders (deceased); censor for one year, R. S. Hill, Montgomery, to fill unexpired term of Dr. I. L. Watkins (resigned). During the meeting a service flag was unveiled, bearing 432 stars, which represent the number of members of the profession now serving as officers in the Army, Navy and United States Public Health Service.

ARKANSAS

Officers Elected.—At the meeting of the Jackson Medical Association at Newport, the following officers were elected: president, Dr. Oscar E. Jones; vice-president, Dr. Ira H. Erwin; and secretary-treasurer, Dr. Elbert L. Watson.

Miscellaneous.—Preliminary work for the control of malaria in the vicinity of Bigelow was begun, March 16, when Dr. Charles W. Garrison, Little Rock, state health officer, and Dr. Homer A. Taylor, went to that place to plan the campaign.——Dr. J. C. Geiger, epidemiologist of the United States Public Health Service, who has been conducting a sanitary campaign in North Little Rock, has transferred his work to Lonoke, where an aviation camp is being built.——A health survey has been completed at Pine Bluff, and committees have been appointed to carry out the recommendations of the report.

CALIFORNIA

Miscellaneous.—From the *Bulletin* of the state board of health it is learned that Dr. Robert A. Peers, Colfax, has been assigned to the American Branch of the Red Cross in France in the interest of the control of tuberculosis in that country.——Venereal diseases are being reported more satisfactorily. In 1917, 2,873 cases of gonococcus infection were reported, as against 1,091 cases in 1916; cases of syphilis were reported to the number of 1,790 in 1917 as against 1,538 in 1916. Forty-five out of the fifty-eight counties in the state reported these diseases, only the mountain counties with low populations failing to report.——Ferndale, in Humboldt County, has established physical examinations in the schools.——The state board of health has condemned the use of sewage for irrigating vegetable gardens and will prohibit the sale of vegetables grown under such conditions, though such fertilizer may be used on grains and grasses, fodder crops, etc., harvested in the dry state.

ILLINOIS

Chicago

Public Health Meetings.—The Chicago Public Health Association, which was organized in July, 1917, and holds meetings in the various school centers throughout the city, was compelled to suspend its activities during the cold weather on account of scarcity of coal. The bulletin of the health department now announces that the meetings will be resumed, since no heat will be required, and the first spring meeting is announced for April 25 in a number of the school buildings on the same evening. For the first meetings two papers will be read, one on prevention of blindness and the other on the ten commandments of health. Both will be short and general discussions will follow. These meetings have heretofore proved of great interest.

INDIANA

Disloyalty Charged.—Dr. Frederick W. Krueger, Richmond, it is reported, has been dismissed from the Wayne County conscription board for disloyal remarks. Dr. Krueger has issued a statement denying the charges and asserting his loyalty to the United States.

Tuberculous Conscriptionists.—Arrangements are being completed by the Indiana Society for the Prevention of Tuberculosis whereby it is hoped that every registrant under the draft law and every man in the service who is rejected on account of tuberculosis, may have an opportunity to regain his health under the care of tuberculosis experts. Names and addresses of all tuberculous soldiers will be sent to the National Society for the Prevention of Tuberculosis and that society will send each state society its list of names. All the work is to be of a confidential nature, in order that a maximum amount of good may be done with the least annoyance to the afflicted men or to members of their families.

KANSAS

State Board Reappointments.—Dr. Harry L. Aldrich, Caney; Oliver D. Walker, Salina, and Charles H. Lerrigo, Topeka, have been reappointed members of the state board of health for a term of three years. Dr. Albert S. Ross, Sabetha, has been reappointed a member of the state board of medical examination and registration for a term of four years.

Personal.—Dr. Herbert L. Clark has resigned as health officer and city physician of Topeka.——Dr. Elmer E. Morrison and Edwin C. Button, Great Bend, sustained painful injuries in an automobile accident near Chase, March 22.——Dr. Middleton L. Perry, for fifteen years superintendent of the state hospital for epileptics at Parsons, has been appointed superintendent of the Topeka State Hospital to succeed the late Dr. Thomas C. Biddle.——Dr. Thomas B. H. Anderson, assistant surgeon, U. S. P. H. S., formerly stationed at Ellis Island in the immigration service, has arrived in Leavenworth to take charge of sanitary work in the cantonment zone.

LOUISIANA

American Hay-Fever Prevention Association.—At a meeting of the American Hay-Fever Prevention Association in New Orleans, April 14, Dr. William Scheppegrell made a report showing that with the cooperation of the city board of health and the mayor in cutting weeds, etc., the hay-fever situation had been improved and there had been favorable comment on the general reduction of weeds. Especially important had been the appointment of a weed cutting day by the mayor in August, 1917. The hay-fever clinic at the charity hospital had demonstrated the practicability of immunization against hay-fever. A department for colored patients has been added to the clinic. All state boards of health in the United States except six are now represented in the association.

MAINE

Epidemic at State Girls' School.—On account of an epidemic of measles and mumps at the state school for girls at Hallowell, the trustees of state juvenile institutions issued an embargo on the sending of more children to these institutions until further notice.

MARYLAND

Measles Almost Epidemic.—Measles is almost epidemic in Baltimore, according to the records of the health department. Five hundred and eight cases have been reported since noon last Friday, the highest weekly record in a year. There has, however, been but one death from the disease so far during the week.

Meeting Postponed.—The meeting of the Medical Library Association in Baltimore has been postponed on account of conditions brought about by the war. The executive committee believes that the energy and money usually put into the meeting could be used to greater advantage in furthering the cause for which the Allies are fighting.

South Baltimore Hospital.—The South Baltimore General Hospital was formally opened to the public during the past week, and a number of patients were admitted. The building will accommodate fifty patients, and there are special medical and surgical wards. Dr. Emil Novak is surgeon-in-chief and Dr. John G. Onnen, his assistant.

Personal.—Dr. Thomas L. Richardson will enter the United States Public Health Service when the government formally takes over Quarantine Station within the next few days. Quarantine is to be taken over by the government under the terms of a lease authorized by the Baltimore city officials, and as soon as a congressional appropriation becomes available, the city will be paid $76,000 for the buildings, grounds and equipment. City patients suffering from quarantinable diseases are to be treated by the government at $1 a day per patient.

Conference on Tuberculosis.—Important subjects were under discussion at the State War Time Tuberculosis Conference held at McCoy Hall, Baltimore, April 18. The conference was divided into two sessions. In the afternoon, the annual meeting of the Maryland Association for the Prevention and Relief of Tuberculosis was held and the following officers elected: Dr. Henry Barton Jacobs, Baltimore, president; Dr. C. Hampson Jones, secretary, and Dr. Joseph S. Ames, treasurer. Dr. Martin F. Sloan, Townson, superintendent of the Eudowood Sanatorium, then spoke on the work of the state hospital and the important cooperative work of the tuberculosis nurses, whose educational propaganda and after-care are adjuncts to sanatorium treatment. At the evening session, Major Joseph A. Chatard, medical officer at the U. S. Army General Hospital No. 2, Fort McHenry, made the principal address on the rehabilitation work at the fort, particularly as it relates to the treatment of tuberculosis patients. Dr. John D. Blake, health commissioner of Baltimore city, and Dr. Allen K. Krause, Saranac Lake, director of the Kenneth Dow Foundation for the Study of Tuberculosis at the Johns Hopkins Hospital also spoke on tuberculosis, its prevention and treatment.

MASSACHUSETTS

Commissioner of Health.—The recalling of Dr. Allan J. McLaughlin to the United States Public Health Service to become Assistant Surgeon-General in charge of the Division of Interstate Quarantine, left a vacancy in the health commissionership, filled by Dr. McLaughlin since November, 1914. The vacancy has been filled by the appointment of Dr. Eugene R. Kelley, who went into office April 1. Dr. Kelley was formerly commissioner of health of Washington, and for three years past has been director of the department of communicable diseases in the Massachusetts organization.

MINNESOTA

Personal.—Dr. Arthur F. Kilbourne, superintendent of the Rochester State Hospital, was stricken with cerebral hemorrhage, March 25.——Dr. D. Edmund Smith, Minneapolis, has left for France to do work among the refugees.——Dr. Homer M. McIntire, Eveleth, connected with the More Hospital, has become interested in a hospital at Ely, Nev.

Five-Day Clinic in Minneapolis.—Under the auspices of the clinical section of the Hennepin County Medical Society, clinics were held in Minneapolis, from April 8 to 12. Clinical facilities were afforded by the fourteen hospitals of the city. A banquet was held at the Radisson, April 8, by the society, and on April 10, the Minnesota Academy of Ophthalmology and Oto-Laryngology entertained the visitors at dinner.

MISSOURI

Personal.—Major Louis P. H. Bahrenburg, surgeon of the United States Public Health Service, Marine Hospital, St. Louis, has been elected medical director of the St. Louis Society for the Control and Prevention of Tuberculosis.——Dr. Dora Greene-Wilson of Kansas City was a guest of honor of the medical women of Chicago at the monthly dinner of the Woman's Medical Club of Chicago, March 31.——Dr. Haynie Rowell of Kearney, a member of Clay County Medical Society, who has served as a member of the school board of the county for the past twenty-one years, has announced that he will not be a candidate for reelection.

Bonds Issued for Hospital.—Audrain County has voted authority to issue bonds to the amount of $75,000 for the erection of a general hospital to be located in Mexico. This is the first county in the state to take advantage of the law passed at the last session of the legislature authorizing any county to establish and maintain a public hospital by levying a tax and issuing bonds therefor. The members of the Audrain County Medical Society were very active in helping to carry the election. A training school for nurses will be established in connection with the new hospital. Mexico Hospital, which has been operating for the past four years, will turn over its equipment, estimated to be worth about $6,000, to the county for use in the new hospital. The success of the Mexico Hospital, which was supported by private subscriptions, was so conspicuous that it served as a stimulus for the passage of the law to issue bonds, the vote being about nine to one in favor of the proposition.

NEW YORK

Course in Neurology and Psychiatry at Neurologic Institute.—Under the direction of Dr. Walter Timme, a course in neurology and psychiatry for medical officers of the Army is being conducted at the Neurologic Institute. The instructors include the entire staff of the institute, and in addition, special courses of instruction at the Mount Sinai Hospital, the Montefiore Home, the Psychiatric Institute at Ward's Island and the insanity wards at Blackwell's Island, are to be given.

New York City

Personal.—Dr. S. S. Goldwater, former health commissioner, has resigned as chairman of the mayor's committee on hospital and medical facilities. He still remains a member of the committee and has suggested plans for its reorganization. Commissioner Coler will assume the duties of chairman.

Training for Nurses Aids.—In view of the increased demand for nurses during the war, the mayor's committee on hospital and medical facilities, in their report of 1917, recommended that the plan for the training of volunteer nurses' aids, now followed in base hospitals under the auspices of the Red Cross nursing service, be accepted and extended to such other hospitals as may be approved by the Red Cross, and that the courses of instruction should conform to this plan and be carried on under its auspices. While the enrolment and training of nurses in the hospitals under the regular plan should be promoted to the greatest possible extent, still it will be found that the numbers will be totally inadequate to take care of the possible 150,000 additional patients it will be necessary to provide for on account of the war, and the training of nurses' aids from among women physically and mentally capable who are desirous of doing patriotic service is the solution of the problem. They will serve under the direction of regularly trained nurses. A course of instruction for these nurses' aids has been prepared by the Red Cross, and the following hospitals have so far undertaken the training of such aids: Bellevue, Brooklyn, German, Mount Sinai, Post Graduate, Presbyterian, Roosevelt, St. Luke's and the Staten Island. Already 411 aids have completed their theoretical and practical training.

OHIO

State News.—The Ohio *Public Health Journal*, the organ of the state department of health, for March is devoted almost entirely to child hygiene and is called the child hygiene number. Its purpose is to promote the saving of the quota of babies assigned to Ohio by the federal Children's Bureau in its baby saving campaign for 1918. Among the articles are state and local programs for child welfare and child saving, and news and statistics of what is being done and what has been done along these lines in the state. There is also an editorial plea for efforts to help attain the low infant mortality rate of New Zealand, which was, in 1912, 5.1 per thousand for children under 1 year of age.——In February twenty cases of smallpox were discovered in a Cleveland parochial school. None of the patients had had medical attention. Four hundred of the pupils were then vaccinated. Nearly 50,000 school children in the city have been vaccinated since last fall, and 104,000 are said to be now protected against smallpox.——At Wellston, where an epidemic of smallpox has been in progress, the board of health has instructed the city solicitor to prosecute the first smallpox victim who, by violation of the quarantine regulations, infected numerous other persons, thus starting the epidemic.

OKLAHOMA

State Hospital Burns.—April 13, the state hospital for insane, Norman, was burned, with a loss of many lives. Three buildings, all frame, were destroyed and the fourth suffered severe damage. Twenty-three bodies have been recovered so far, and four patients are missing. The deaths were all in Ward 14, and the victims were negroes. The patients in the other buildings were removed in safety. The property damage is estimated at $40,000. The legislature of 1916 passed an appropriation of $85,000 to construct a modern fireproof building, but the fund has only recently become available.

OREGON

Personal.—Dr. Esther C. Pohl Lovejoy of Portland has returned from France, where she has been the last four months as a special representative of the Red Cross in the department of civil affairs, which is entrusted with the work of giving relief to the civilian population of France and Belgium. She will be attached to the civilian relief service of this country.——Dr. J. E. Anderson, Salem, has filed his declaration as a candidate for nomination for governor.——Dr. Henry J. Kavanaugh has been appointed city physician at Pendleton to succeed Dr. Hillis H. Hattery, who has resigned to enter the Medical Service of the Army.

PENNSYLVANIA

Personal.—Dr. Jane R. Baker of West Chester has been appointed by the government as trustee of the Asylum for the Chronic Insane at Wernersville.

Philadelphia

Personal.—Dr. George Woodward, trustee and chairman of the bureau of municipal research since its organization nine years ago, resigned recently.

Health Day.—Health day will be celebrated in the schools and throughout Philadelphia, May 1. A mass meeting will be held at the academy of music when former President William H. Taft will deliver an address on "Health and Its Value in the Present Crisis." Dr. Alice W. Tallant, who has returned after several years service in France, will also be one of the speakers.

Naval Hospital to be Enlarged.—The United States Naval Hospital at Gray's Ferry Road and the hospital at the Navy Yard will both be enlarged. Additional buildings will be erected at the Gray's Ferry institution and two wards will be added to the building at the Navy Yard to accommodate 800 more beds. At present, the capacity at the former institution is 500 but the addition will total a capacity of 1,400, and $355,000 has been appropriated for the work there, and $800,000 has been appropriated for the work at the Navy Yard.

VERMONT

School Medical Inspection.—Burlington and Rutland are the only two cities in the state, it is said, who have school medical inspection. The proposition to establish such inspection in the schools in various towns of the state has always been voted down. In Burlington, during 1917, the cost of this inspection in twenty-two schools was $1,358.26.

Personal.—Dr. David Marvin of Essex Junction has been named as treasurer of the Vermont State Medical Society to fill the vacancy caused by the death of Dr. Edward H. Martin of Middlebury.——Dr. Fred A. Edmunds, Bethel, is convalescent from an operation for chronic appendicitis.——Dr. Henry J. Potter, Bennington, was fined $150 for violation of the Harrison Narcotic Law, after pleading guilty.

Health Officers' School.—A school of instruction for health officers of the state will be held at Burlington beginning May 21 and continuing through the morning of May 23. Attendance is compulsory unless the officers are excused by the state board of health. Each health officer will be allowed $4 per day and actual expenses while in attendance. Programs and announcements are to be distributed later.

Analysis of Butter Substitutes.—The increased use of butter substitutes on the request of the federal food administration led the state authorities to examine various products in the laboratory. Olemargarin was selected and twenty-four different brands found in Burlington and three others obtained at St. Albans were examined in December and January. Six of the twenty-seven brands were the so-called nut margarins, made entirely or largely of vegetable fats. One brand tasted old and rancid; the others had the usual tastes of the different oleomargarins. The *Bulletin* of the Vermont State Board of Health, from which the information is obtained, says that there is no standard for oleomargarin, but the requirements for butter are that it contain not less than 82.5 per cent. of butter fat and not more than 16 per cent. of moisture. The average weight of the 27 "pound" samples was 16.1 ounce; the highest weight was 17 and the lowest, 15.5 ounces. The average moisture content was 10.1; the highest was 19.8, the lowest, 5.9. The average fat content was 82.2; the highest was 90.4, the lowest, 77.7. The average cost of the samples was 33 cents; highest, 38; lowest, 25 cents.

GENERAL

Cod Liver Oil.—According to *Commerce Reports*, 58.140 gallons of cod liver oil valued at $176,022 was invoiced at Bergen, Norway, for the United States during 1917.

Venereal Clinics.—The American Red Cross, according to the *Social Hygiene Bulletin*, has recently made allotments for the establishment of venereal clinics at Newport News, Va.; Charlotte, N. C.; San Antonio and El Paso, Texas; Louisville, Ky., and Chillicothe, Ohio, under the direction of the sanitary officers of the United States Public Health Service. A social worker will be assigned to each from the United States Army.

Site for Leprosarium.—Surgeon-General Rupert Blue of the Public Health Service has appointed a committee to select a site for the proposed leprosarium for which Congress in 1917 appropriated the sum of $250,000. The committee consists of Surg. George W. McCoy, director of the Hygienic Laboratory, Dr. William C. Woodward, health officer of the District of Columbia, and Dr. Charles V. Chapin, health commissioner of Providence, R. I.

Coal Mine Fatalities in 1917.—In a preliminary statement of coal mine fatalities in the United States in 1917, compiled by Albert H. Fay of the bureau of mines, it is said that the abnormal conditions under which the coal mines were operated in 1917 are reflected in the accident records by an increase of 21 per cent. in fatalities as compared with 1916. There was an unusual demand for coal but the production increase was less than 10 per cent. It is said that it is impossible to give the number of men employed in the industry, but the number was increased in some states while in others there was a decrease. It is believed, however, that the number is practically the same as was employed in 1916, namely, 720,971. The demand for coal increased the number of working days for the men for the year in mines favorably situated and supplied with cars, and this increased the hazard of injury and fatality to the individual miner, as his risk is proportional to the time he is exposed. In other mines not so favored by the car supply, work was interrupted, and this again increased the hazard from certain dangers such as gas, dust, falls of roof, etc., as an active mine will ordinarily be kept in better condition than one operated only part of the time. The fatalities grouped by principal causes show an increase for falls of roof of 185, or 19.23 per cent., and for mine cars and locomotives underground an increase of 23.59 per cent. Haulage on the surface shows an increase of 52 per cent. Fatalities produced by explosives and electricity show a decrease of 24 per cent., there being 111 deaths for 1917 as against 146 for 1916. The record for 1917 shows that any relaxation in inspection, safety measures, and supervision, or any temporary disorganization of the industry, or any increased demand for coal immediately results in higher accident records.

FOREIGN

Thompson Memorial Lecture.—April 9, Sir Ernest Rutherford delivered the first "Silvanus Thompson Memorial Lecture," in memory of the first president of the Roentgen Society, London.

Antwerp Physicians Penalized by the Germans.—The *Presse Médicale* relates that at the recent court martial Dr. Demets was condemned to be shot and Drs. François, Bremken and van den Wildemberg were sentenced to hard labor for life.

Closer Connection Between Universities.—A conference has been called at London, May 9, of representatives of the various universities to discuss the possibility of closer connection between British universities and those of the allied countries.

The Delanglade Souvenir Medal.—A subscription has been opened to erect a bust of Prof. E. Delanglade at the scene of his labors in the city hospital at Marseilles and distribute souvenir medals to the subscribers. His death at the front was recently mentioned.

Spanish Medical Students to Study Emergency Surgery at the Front.—The government of Spain has appropriated 30,000 pesetas to pay the expenses of a party of medical students to visit an advanced hospital of the French army. One student is to be selected among the most advanced of each of the seven medical colleges of the country, and some eminent surgeon will head the party. To study the progress realized in emergency surgery is the main object of the expedition.

Prizes Awarded by the Spanish Academy.—Seven prizes were distributed at the recent annual meeting of the Academia Nacional de Medicina at Madrid, the cash prizes totaling over 41,000 pesetas, about $8,200. The themes included vaccine therapy, medical geography and epidemics. One prize goes annually to the professor in the university who has contributed most to the progress of science, and one to a city physician, married and with children, who has sent in the best report on some epidemic.

Deaths in the Profession Abroad.—**L. Revilliod,** professor of clinical medicine at the University of Geneva. In collaboration with Binet, he published tables showing the damage wrought by alcohol in different organs.——**B. H. Stephan,** director for twenty-five years of the public hospital at Amsterdam and since then medical inspector for the northern provinces of the Netherlands.——**R. S. Trevor,** lecturer on pathology and dean of St. George's Medical School at London, aged 46.——**G. A. Petrone,** lecturer in pathology and pediatrics at the University of Naples, aged 44.——**C. Sauvage,** professor agrégé of obstetrics at the University of Paris, aged 44.

Rehabilitation of the Maimed.—The federation of those specially interested in the training of wounded soldiers is organizing provisions for the purpose in every province in Italy. Where nothing of the kind has yet been organized, committees of seven members are being appointed to consider ways and means. The committee consists of the medical officer of the province, a representative of the provincial government, two soldiers crippled in the war, one factory inspector, one representative of the hospitals in the region, and one lawyer to be appointed by the bar association. This committee is to appoint subcommittees, so that this welfare work for the war cripples will be extended to the remotest towns.

Organization of the Profession in Spain.—The minister of war has asked the members of the medical military department of the Spanish army and navy to cooperate in making a success of the first national medical congress which is to be held at Madrid, from October 13 to 18 of the current year. Leave of absence is to be granted to all to attend the meeting, when it does not conflict with the service. The navy is also empowered to appoint a committee to organize a special navy exhibit as an auxiliary to the congress. This meeting is organized with the distinct purpose of founding the Spanish Medical Association, under official auspices, to form a permanent organization to hold annual meetings thereafter in different medical centers of the country. Already 800 physicians have sent in their names, and an attendance of 2,000 is anticipated. A scientific and welfare work exhibition, to be kept open a month, is to open with the congress.

CENTRAL AND SOUTH AMERICA

Eighth Brazilian Medical Congress.—The Academia Nacional de Medicina has the preparations well under way for the eighth Brazilian medical congress to convene in September of this year at Rio de Janeiro.

The Arteaga Ward.—One of the wards of the new Garcia Hospital at Havana has been named in honor of Dr. Serapio Arteaga, a leading obstetrician of Havana in his day and professor of gynecology and obstetrics in the university. His portrait was installed with much ceremony in the new ward recently. His son is editor of the *Revista de Medicina y Cirugia.*

CORRECTION

Health Officer of Aberdeen, S. Dak.—In the issue of The Journal for April 13, under the heading of South Dakota, appeared the following personal item: "Dr. Thomas B. Christian, South Bend, Ind., bacteriologist and pathologist, has been appointed city health officer of Aberdeen." We have since been informed that it was Dr. Louis Holtz, bacteriologist and pathologist of the city hospital of Springfield, Ohio, who was appointed health officer of Aberdeen.

ARGENTINE LETTER

Buenos Aires, March 14, 1918.

Mortality from Tuberculosis

The mortality from tuberculosis in the last four decades has dropped from twenty-seven per ten thousand inhabitants to 17.4. The lowest point was reached in 1913, when it was only 16.4, but it has progressively risen since. This increase in the mortality coincides with conditions created by the war.

Official Organ of the State Bacteriologic Institute

This institution, an important department of the national public health service, located at Buenos Aires, has recently started the publication of a quarterly review. The first issue was indexed and reviewed in the foreign literature department of The Journal, March 16, 1918, p. 819.

Impressions of a Trip to the United States

Dr. R. Finochietto of Buenos Aires has returned from a visit to the principal surgical clinics of the United States, and is publishing in the *Semana Medica* the impressions received. North American surgery has acquired prestige in Argentina, especially among the younger set of surgeons.

Cancer Mortality

According to data published recently, the mortality from cancer during the last thirty years at Buenos Aires has been eighty per hundred thousand inhabitants. The annual number of cases has declined since 1887.

Reduction of Mortality from Infectious Diseases

The statistics in regard to infectious diseases at Buenos Aires, published by Dr. E. R. Coni in the *Semana Medica* for Dec. 13, 1917, show a considerable reduction in recent years. In the decade from 1877 to 1886 the mortality per ten thousand inhabitants was 332; in 1887-1896, it was 354. Then it dropped to 111 in 1897-1906, and finally to 66, in 1907-1916. As already mentioned in The Journal, page 1045, the mortality from smallpox has reached the vanishing point, the proportional mortality in the decades cited being respectively, 140, 100, 42, 8 and, during 1916, 0, since no deaths from smallpox were reported during that year. This result is due to intensive compulsory vaccination.

Vaccination Against Rabies

The report of the Antirabies Institute at Buenos Aires, embracing the last thirty years, was published recently in the *Semana Medica*, Feb. 14, 1918. Of the total 19,609 persons given treatment, ninety-eight died, that is, 0.049 per cent. Of this number, only sixty-two died later than fifteen days after completing treatment, that is, 0.031 per cent. The injections of medulla tissue are given twice a day, the scale being: 10/9, 8/7, 6/5, 5/4, 4/3, 3/2, 1; 4/3, 2/1; 4/3, 2/1; 3/2, 1; 3/2, 1.

CUBA LETTER

Havana, April 10, 1918.

The Cure of Leprosy

A little over a year ago a farm laborer, a native of the Canary Islands and for many years a resident of Cuba, claimed that he had discovered a wonderful cure for leprosy; he said that he himself, who had been a leper, was cured. His method was at first kept a secret, and he began to advertise, saying that he wanted only glory and no money. The newspapers sent their reporters to interview this magician of medical science, and they for some reason or other praised the man and his wonderful discovery. In fact, his medicine is chaulmoogra oil given by mouth suspended in a decoction of some herbs, and he claims that he can administer a thousand drops of the oil without the untoward results noted when the drug is given alone.

The Academy of Sciences, the Society of Clinical Studies, and the Board of Health of Cuba appointed a joint commission to study the procedure for the cure of leprosy discovered by this man, Mr. A. Garcia, who said that he could restore any patient to complete health in three months. He was given eight months to prove his assertion, and several patients from the National Leper Hospital were placed under his treatment; when the eight months had elapsed the commission reported that Hansen bacilli were still present in all cases, that there was very little if any improvement in all the patients, and that Mr. Garcia's treatment, therefore, was not at all curative. Mr. Garcia's friends raised a storm against the commission, saying that the patients were greatly improved and that the presence of Hansen bacilli in all the cases was of minor importance.

We think that we are facing a case of plain quackery, for we positively know that this man is making money on his supposed discovery for the cure of leprosy, and even more, we know of several cases of lupus vulgaris, syphilis, psoriasis, etc., treated by this man under the diagnosis of leprosy.

New Clinics

Drs. E. Fortun and B. Souza have established a new surgical clinic in Havana.

Dr. L. Huguet has recently opened an obstetric clinic in Vedado, Havana.

The School of Preventive Medicine

At the fourth National Medical Congress, held at Havana, last December, Dr. J. F. Pazos read a paper suggesting the founding of a school of preventive medicine and hygiene, a proposition that has since been seriously considered. The Society of Clinical Studies and the Academy of Sciences support Dr. Pazos' idea. We consider the creation of a school where Cuban physicians may be especially instructed in hygiene and sanitation almost a necessity. Here in the tropics we are forced to fight incessantly many diseases, such as malaria and typhoid fever, and it would be very convenient to have a corps of scientifically trained men for this purpose. At present, those engaged in this work are self-trained men or those who have gone abroad for their studies.

Malaria Appears in Camagüey Province

Dr. F. Villuendas has been commissioned by the Central Board of Health of Cuba to eradicate malaria from Ciego de Avila and suburbs (Camagüey), where many cases of malaria have been reported. Dr. Villuendas is already working with a brigade of sanitarians and several ambulances, and his reports are very satisfactory.

New Hospital for Children

The corner stone of the first hospital for children was recently laid in Pinar del Rio City. This is the first of the six hospitals to be constructed, one in each of the six provinces of Cuba. At present the children of this country have a seaside sanatorium at Cogimar (Havana Province) besides the regular wards in the hospitals.

LONDON LETTER

London, March 26, 1918.

Opening of a New American Hospital in London

In the presence of a distinguished company, which included Admiral Sims of the U. S. Navy, Sir William and Lady Osler, Surg.-Gen. Sir Alfred Keogh and Sir Robert Jones, the American ambassador opened the American Red Cross Hospital No. 24 (the fifth to be opened in this country) at Kensington Palace Gardens. It has been presented and equipped and will be maintained by Mr. and Mrs. A. Chester Beatty of New York. The hospital is auxiliary to the British military orthopedic hospital at Shepherd's Bush. The medical and nursing staffs are entirely American. There are eight wards, and accommodation for thirty-six orthopedic patients. The color scheme of eider downs and screens is pale blue in some wards, golden brown in others and rose in the remainder, and the walls are oyster white. The wards bear the names of famous Americans—George Washington, Stonewall Jackson, Robert E. Lee, U. S. Grant, Abraham Lincoln, Alexander Hamilton, Thomas Jefferson and Benjamin Franklin. Ambassador Page said that it was a great honor, not only for himself but for his government, to thank Mr. and Mrs. Chester Beatty for the generous service they had done in giving this house for use as a hospital, and in themselves paying the expenses. Until needed for American wounded it would be filled with British and colonial patients, and the donors, like all true Americans, would be as pleased that this use should be made of it as if it were to be used for the healing of their own soldiers. It brought home to them what this terrible conflict meant. "Let us," he continued, "fortify our courage and strengthen our resolve under God not to waver until this grim and righteous business be done with, and let us dedicate ourselves to the noble ideals our armies fight for, and do all we can to further the cause that is at stake in this critical time."

Tetanus in Home Military Hospitals

In a previous letter (The Journal, Jan. 5, 1918, p. 45) was given an analysis by Sir David Bruce, on behalf of the

Tetanus Committee of the War Office, of the cases of tetanus treated in the home military hospitals and the conclusions to be drawn from them. He has now published an analysis of 100 further cases. The death rate was 29 per cent. as against 19 in the previous analysis, which was by far the lowest of the series. Sir David Bruce thinks that the present mortality is little more than can be expected from the prophylactic and therapeutic use of antitetanic serum, and that it now remains with the surgeons to do the rest. It should not be "beyond the ingenuity of man to devise some form of surgical treatment which will prevent the development of gas gangrene or tetanus in wounds." Eighty of the cases belonged to the generalized type of tetanus; of these, twenty-nine were fatal, while in the twenty localized cases, all the patients recovered. Thirten cases of tetanus ocurred after operative interference with the wound, and nine of them were fatal, a death rate of 72.7. In none of these was a prophylactic inoculation of antitetanic serum given before the operation, although the Tetanus Committee has advised that when operations are performed at the site of wounds, even if they are healed, a prophylactic injection of serum should invariably be given. With our present knowledge, Sir David thinks, it is a question as to whether a surgeon who neglected this prophylactic injection would not render himself liable to an action for malpractice. Notwithstanding the Tetanus Committee's advice in favor of the intrathecal route and of the evidence from animal experiment, the intramuscular route is steadily becoming more popular. This, he thinks, is scarcely to be wondered at, since in the latest edition of a well known textbook on medicine the intramuscular route is strongly recommended; its ease and freedom from danger are doubtless in its favor.

Transmission of Trench Fever by the Louse

In a recent letter (The Journal, Feb. 23, 1918, p. 553) the results of a committee appointed by the War Office to inquire into the nature of trench fever were given. This investigation was made in France and was altogether clinical. Another committee working at home, under the chairmanship of Sir David Bruce, has made a remarkable discovery as to the etiology. In view of the widespread belief that the body louse conveys the disease, experiments were made. Lice bred from "clean stock" were fed on trench fever patients. Two volunteers, men well over the military age, and therefore unable to serve their country in more strenuous ways, came forward from patriotic motives. The lice were fed on them, the shortest interval between this and feeding on the trench fever patient being six hours. This experiment was continued daily for a month at least 500 lice being used every day, but no positive results were obtained. At a meeting of the committee the question was asked, Did these men scratch themselves? It was found that they did not, and, indeed, purposely refrained from doing so. This excluded to a large extent infection by means of excreta or crushed bodies of the lice. Two more volunteers were therefore found. In the case of one an area of skin 1 inch square was scarified, and a small quantity of the dried excreta taken from the boxes of lice that had fed on trench fever patients was dusted on this area and rubbed in. Nine days later the man was suddenly attacked with typical trench fever. On a scarified area of the other man's arm, eleven lice taken from a trench fever patient were crushed. Eleven days later he was attacked with trench fever. The fever which these men developed was indistinguishable from that produced in other volunteers by injection of whole blood from trench fever patients. In view of the importance of this discovery, the experiment was repeated on three other men with positive results. The chain of evidence was completed by the fact that a small quantity of blood taken from one of these and inoculated into another volunteer produced trench fever. In every case the fever, though mild, was yet typical of trench fever—sudden onset, temperature of 103 F., pain in the head and limbs, and over the spleen, the initial attack of fever lasting two or three days, and followed in practically every case by a relapse or relapses at an interval of usually seven days; the fever in the relapse being lower and more transient, with a recurrence of the symptoms associated with the initial attack. This observation is of great importance in view of the prevention of the disease, and would explain cases of trench fever arising in wounded men who may have had no lice on them for some weeks, as the dried excreta, if blown on a raw surface, would readily give rise to the disease. Some further experiments on the migration of lice are also of great interest. It has been shown that if two men are available, one with a normal temperature and the other with fever, the lice will leave the fever patient and pass quickly to the man with the normal temperature. Experiments are now in progress with the excreta of normal lice, as it is possible that the disease is not necessarily carried from man to man by lice but simply from louse to man.

The Smallpox Outbreak in London

The number of cases of the smallpox outbreak in the East-End of London now amounts to twenty-seven. The greatest care has been taken in tracing "contacts." It was thought until a few days ago that they were all under observation and that therefore no further serious spread would occur. It was then ascertained that a person suffering from smallpox in its earliest stages spent several hours in an air-raid shelter. As not all the contacts with this person can be found, further extension of smallpox is not unlikely. Every person living in or near localities in which cases of smallpox have occurred, who has not been successfully vaccinated since childhood, is enjoined to secure this protection.

PARIS LETTER

Paris, March 21, 1918.

Operative Treatment of War Fractures

Dr. Dupuy de Frenelle, surgeon at the hospital Péan, recently discussed the operative treatment of war fractures before the Society of Surgeons of Paris, and dwelt particularly on the coaptation of the fragments. From the very first, the surgeon should aim to bring the bone ends together with the largest contact surface possible in order to maintain the permanence of their contact. The degree of perfection of the coaptation will be proportional to the degree of operative disinfection of the coaptated surfaces. Nothing is so dangerous as to join hermetically surfaces which are still infected. For the coaptation, cut the ends of the fragments on a long and broad bevel; a notch may render the coaptation more solid. Coaptation with a transverse section is more difficult to maintain. Frenelle avoids sawing off the jagged edges, preferring to employ the rongeur or gouge. The employment of the plaque is equally indicated. Coaptation by reciprocal impaction is excellent, but the disinfection must be complete. Coaptation by the implantation of a beveled stump in the medullary canal of the stump by a transverse section will be the more solid the longer the pointed fragment. It must be certain before having recourse to this procedure that the disinfection of the implanted fragments is perfect. If there is any doubt, open widely the marrow canal over the inserted fragment. A V-shaped suture, or, in certain cases, tying a wire around, will render the implantation more solid. In the coaptation of fractures in three fragments, the chief object of the surgeon must be to preserve an intermediate fragment; but Frenelle said that frequently in war surgery the surgeon must do the best he can. He is often obliged in the course of his intervention to modify the plane of the freshening of the bone ends, and the direction of the cut that he had proposed to make, basing his action on a careful study of the stereoroentgenogram and a thorough clinical examination.

The Oil Boils of Shell Turners

At the last meeting of the Academy of Medicine, Dr. George Thibierge called attention to a lesion now frequently seen and known by the name of "oil button" (*bouton d'huile*), an affection characterized in its more advanced stages by rounded pustules from 2 to 8 mm. in diameter, slightly raised, with resistant walls and containing a thick pus. The pustules after being opened leave for a week or two a gaping opening surrounded by a light inflammatory areola which disappears slowly. These lesions are found on the hands, the forearms, the face and places directly exposed to contact with lubricants, and also on parts of the body in contact with oil soaked clothing, especially the anterior surfaces of the thighs. The present necessity in industry of using as lubricants various oils of inferior quality having irritant properties, and which because of their scarcity must be reused without proper purification, favors the production of the "oil button." This lesion has a slow development, and is preceded by the progressive obliteration of the gland mouth, and must be considered, according to Thibierge, as an occupational malady and not as an industrial accident.

Air Raids and the American Red Cross

During the last air raids on Paris, the different services of the American Red Cross particularly distinguished themselves. In these instances their ambulances arrived first at the points of fall of the bombs. In addition, the managers have informed the chief of police that they are prepared to care for victims, who, without being wounded, find themselves without shelter and in need. Furthermore, an emergency station for victims of bombs containing *gas asphyxiants* has been organized by the American Red Cross on the Place de la Concorde in Paris.

Medical Aid in Case of Air Raids

M. Mourier, under secretary of state for the army medical department, in conjunction with the director of the Service de Santé of the military government of Paris, has taken the following measures to secure medical aid to the population of Paris in case of bombardment: A permanent military medical day and night service in the twenty-four barracks and central stations of the fire department, having for its object the rapid transport of the wounded to a first-aid post or to a surgical center. All sanitary formations of the military government of Paris will constitute first aid stations. Surgical service will be provided, besides, in the public hospitals. All the wounded whose condition shall necessitate surgical intervention will be transported by ambulance to a surgical center. The Service de Santé of the military government of Paris will have in reserve supplementary surgical teams of nurses to be sent by automobiles to the point where their services are required.

Franco-Anglo-American League Against Cancer

There has been formed under the presidency of Justin Godart, formerly undersecretary of state for the military Service de Santé, a Franco-Anglo-American league against cancer, having for its object the establishment of centers for the treatment of cancer patients and to pursue scientific researches in cancer, to propagate among the public elementary knowledge concerning this malady, and to create centers of teaching. Three centers are being now organized: at Montpellier, under the direction of Professor Forgues; at Lyon, under the direction of Professor Bérard and of Auguste Lumière; at Bordeaux under the direction of Professor Chavannaz.

The "House of the Little Ones"

There has been inaugurated at Paris a hospital for infants of early age called the "Maison des Petits." This new hospital of twenty-five beds has been founded by two Americans, Mrs. W. B. Elkins and Mrs. Laws, under the auspices of the New York Committee of the French Heroes' Fund. It is intended for infants suffering from maladies of nutrition. The infants will be cared for by American nurses under the direction of Miss Neilsen, of Bellevue Hospital, New York, with whom French nurses have promised to join. It is also proposed to care for infants at their homes when conditions are sufficiently favorable to assure their recovery at home.

Suppression of Alcoholism

The commission of propaganda through the press of the National League Against Alcoholism came together recently under the presidency of M. Chailley, formerly deputy. Frédéric Riémain, secretary general of the league, has solicited the aid of the press for the campaign of prohibition. After an exchange of observations, the commission decided, in case the prohibition of alcohol is not voted by the governments, to support all amendments having for their object the effecting of a diminution in the consumption of alcohol.

Personal

At the last session of the Academy of Medicine, an election was held to fill the places of Dr. Duguet and Professor Reclus in the section of internal pathology and external pathology, respectively. To the former Dr. Pierre Teissier was elected by 55 out of 62 votes, and to the latter, Dr. Felix de Lapersonne was elected by 49 out of 61 votes.

Unilateral Arthrotomy with Primary Total Suture of Wounds of the Knee Joint

At a recent meeting of the Paris Société de chirurgie, Dr. H. Barnsby reported twenty cases of unilateral arthrotomy along a lateral margin of the patella with primary suture, including seven cases with included fragments and gross lesions of the femoral epiphysis (unicondylar), and two cases of comminuted fracture of one lateral half of the patella.

After having been long an ardent partisan of extensive arthrotomy with a U-shaped incision, Barnsby now reserves that incision (horseshoe shaped) for the following cases: (1) severe lesions of the upper articular surface of the tibia; (2) lesions of both condyles; (3) complete comminuted fracture of the patella, and (4) embedded projectiles, difficult or impossible of removal through a lateral opening. In all other cases, especially severe fractures of one condyle or of a lateral half of the patella, one can and should be content to make the single incision along one of the lateral borders of the patella. This procedure causes less trauma of the architecture of the joint, and a return of normal function is obtained more rapidly. The lateral incision is made at least 1 cm. behind the border of the patella, and should be short, if it is a question of removing a free foreign body or one driven into the synovia or the cartilage, and large if it is a question of an osseous lesion.

If it is a patellar lesion, the leg should be placed in extension; if it is a condylar lesion, the leg should be placed in a flexed position during the operative intervention. The loss of bone tissue may or may not be supplied by fragments of cartilage; the functional result is equally good. The ether bath should be applied in both instances. The primary suture should be complete without drainage.

EXERCISING THE KNEE

Barnsby immobilizes the knee for nine days in a simple splint. The day following the removal of the sutures, active mobilization or motion is begun, the patient being recumbent. With the assistance of a simple stirrup of adhesive plaster and a cord passing through a pulley and supporting a weight of from 2 to 6 kg., the patient commences to flex the knee joint as far as possible. This exercise is done twice daily, morning and evening, for ten minutes each time. If properly instructed, the patient soon will be able to do this for one hour, morning and evening, and even three times daily. When the extreme limit of flexion is attained, a specially made cushion maintains this position for fifteen or twenty minutes. Right angle flexion was obtained, without any complications, within twenty days in nine of the ten cases. He has never seen any case of effusion requiring many punctures. This active mobilization, which makes the patient "walk in his bed," is the method of choice in the advanced centers where operations are done on joints only when there are several wounds, such patients being often in shock, and bed rest being compulsory.

Association News

THE CHICAGO SESSION

Clinics for Visiting Physicians

The chairman of the subcommittee on clinics, Dr. Charles E. Humiston, reports that satisfactory progress is being made in the work of arranging for the clinics for the Fellows of the Association on June 6 to 11. Forty of the hospitals of Chicago are cooperating with the committee. In addition to the usual clinical demonstration of diseases and surgical procedure at the hospitals, there will be demonstrations and exhibits of laboratory and other diagnostic measures at the medical schools as well. The committee is also perfecting arrangements which will permit visitors to attend the autopsies held daily at the Cook County Hospital. A detailed schedule of these clinics is being arranged which the committee expect to make available to interested Fellows in a short time.

Marriages

Lieut. Frank Garm Norbury, M. R. C., U. S. Army, Boston, on duty at Camp Devens, Mass., to Miss Mary Elson Barnes of Jacksonville, Ill., at Jacksonville, April 11.

Lieut. Herbert Seth Anderson, M. R. C., U. S. Army, Burlingame, Calif., on duty at Camp Kearny, Linda Vista, Calif., to Miss Linda Jessop of San Diego, April 6.

Lieut. Robert du Rant Harden, M. R. C., U. S. Army, San Francisco, to Miss Hermina Gardner Lathrop of Palo Alto, Calif., at Alta Vista, Calif., April 4.

Hunter S. Woodberry, University, Va., to Miss Ruby Fontaine Davis of Enon, Va., at University, Va., April 7.

Lewis Stockton Walton, Altoona, Pa., to Miss Edith Christie Baldrige of Hollidaysburg, Pa., April 6.

Lieut. Howard Hoge Warner, M. R. C., U. S. Army, to Miss Ruth Stone, both of Baltimore, April 10.

Deaths

Irving Allison Watson, Concord, N. H.; University of Vermont, College of Medicine, Burlington, 1871; aged 66; a Fellow of the American Medical Association; president of the New Hampshire Medical Society in 1903; secretary and executive officer of the state board of health since its organization in 1881; formerly secretary of the American Public Health Association; president of the International Conference of State and Providential Boards of Health, in 1903; assistant secretary general of the first Pan-American Medical Congress, and an honorary member of many American and foreign scientific bodies; author of many papers on medicine, and sanitary subjects; died at his home, April 4.

Cyrus B. King, Pittsburgh, Pa.; Jefferson Medical College, *Philadelphia*, 1862; aged 78; a member of the Medical Society of the State of Pennsylvania; formerly emeritus profe[illegible] urgery and clinical surgery in the [illegible], formerly superintendent of the West Pennsylvania Hospital, and the Pittsburgh Soldiers Home; for many years a member of the staff of the Allegheny General Hospital, and the Children's Memorial Hospital; formerly consulting surgeon at the McKeesport Hospital; died at his home, April 9, from paralysis.

Died in the Service
IN FRANCE
Lieut. Perry S. Gaston, M. R. C.,
U. S. Army, 1889-1918

Bennett Graves Henning, Memphis, Tenn.; Bellevue Hospital Medical College, New York City, 1870; aged 68; formerly Fellow of the American Medical Association; formerly professor of principles and practice of medicine, and clinical professor of diseases of the rectum at the Memphis Hospital, Medical College; a member of the board of directors of the Presbyterian Home Hospital, Memphis; died at Florence Villa, Fla., March 30.

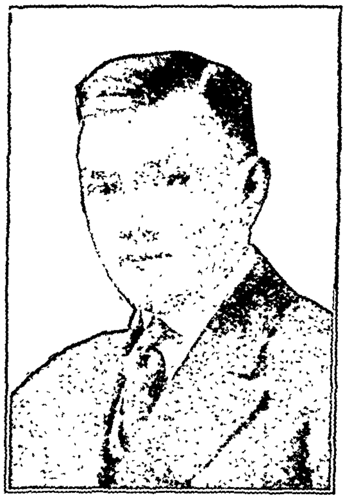
Lieut. Frederick Neel Henderson, M. R. C., U. S. Army, Rockville, Md.; University of Pennsylvania, School of Medicine, Philadelphia, 1903; aged 37; a Fellow of the American Medical Association; formerly president, and up to the time of his death, secretary and treasurer of the Montgomery County Medical Society; on duty at Fort Oglethorpe, Ga.; died in a base hospital, April 8, from cerebrospinal meningitis.

Lieut. Perry S. Gaston, M. R. C., U. S. Army, Newcastle, Pa.; Jefferson Medical College, 1912; aged 28; a Fellow of the American Medical Association. Dr. Gaston was killed in action, April 7. He enlisted in June, and was called to duty in August, being sent immediately to England and attached to the British Medical Service. It is reported that he was with the British forces about Amiens when he was killed.

Martin Krotoszyner, San Francisco; University of Leipzig, Germany, 1887; aged 56; a Fellow of the American Medical Association; vice president of the Section on Genito-Urinary Diseases of the American Medical Association; a member of the American Urological Association; formerly urologist to the German Hospital, San Francisco; was shot and killed in his office, April 20, by one of his patients.

Lieut. Julian Neal Dow, M. R. C., U. S. Army, Arcola, Ill.; Bennett Medical College, Chicago, 1915; aged 24; on duty with the British Field Hospital Service; was killed while on duty in France, March 27.

Andrew J. Rodman, Delavan, Wis.; Rush Medical College, Chicago, 1865; aged 87; formerly a member of the State Medical Society of Wisconsin; died suddenly at the home of his daughter, about April 1, from diabetes.



Died in the Service
AT CAMP UPTON, N. Y.
Lieut. Gustaf Lewis Norstedt, M. R. C., U. S. Army, 1892-1918
(*See The Journal, April 6, p. 1023*)

Died in the Service
AT FORT OGLETHORPE, GA.
Lieut. Frederick Neel Henderson, M. R. C.,
U. S. Army, 1881-1918

William B. Scott, Cumberland City, Tenn. (license, Tennessee, 1889); aged 70; president of the Cumberland City Bank; [illegible] home, about March 28, from heart disease.

Thomas B. Fernalld, Norwich, N. Y.; University of Buffalo, 1889; aged 54; a member of the Medical Society of the State of New York; formerly a coroner and village health officer for several years; died at his home, March 26, from cancer.

Thomas Smith Shouse, Mount Eden, Ky.; Hospital College of Medicine, Central University, Louisville, 1892; aged 50; formerly a Fellow of the American Medical Association; died at his home, about March 31, from diabetes.

Died in the Service
IN FRANCE
Lieut. Edward Leland Mooney, Jr., M. R. C.,
U. S. Army, 1892-1918
(See The Journal, April 20, p. 1182.)

James Edward Buckley, Chicago; College of Physicians and Surgeons, University of Illinois, 1905; formerly a Fellow of the American Medical Association; died in Washington, D. C., April 2, from wounds, self-inflicted.

Died in the Service
AT CAMP LEWIS, WASH.
Capt. Malcolm J. Denney, M. R. C.,
U. S. Army, 1872-1918

Marius Emmet Robinson, Goldsboro, N. C.; Washington University School of Medicine, Baltimore, 1870; aged 70; a member of the Medical Society of the State of North Carolina; died at his home, March 24.

Frederick Perley Jones, Mill Village, N. H.; New York University Medical College, 1878; aged 64; a member of the New Hampshire Medical Society; died at his home, January 18, from cerebral hemorrhage.

Capt. Malcolm J. Denney, M. R. C., U. S. Army, Portland, Ore.; University of Oregon School of Medicine, Portland, 1897; aged 46; died, March 27, at Camp Lewis, American Lake, Wash., from pneumonia.

R. H. Payne, Richland, Iowa; College of Physicians and Surgeons, Keokuk, 1863; aged 81; formerly a member of the Iowa State Medical Society; died at his home, February 10, from arteriosclerosis.

Valter P. Stevens, Poulan, Ga.; University of Louisville, Medical Department, 1891; aged 46; formerly a member of the Medical Association of Georgia; died at his home, April 2, from pneumonia.

Alfred Herbert Tanner, Brooklyn, Conn.; Bellevue Hospital Medical College, New York City, 1874; aged 65; a member of the Connecticut State Medical Society; died suddenly, March 29.

Joseph Dodson Lomax, Troy, N. Y.; College of Physicians and Surgeons, New York City, 1862; for many years superintendent of the Marshall Infirmary of Troy; died about March 23.

Sutherland Douglas Twining, Springfield, Mass.; Yale University, Medical Department, New Haven, Conn.; 1864; died in the Buffalo State Hospital, February 8, following a fracture.

James Thurston Martin, Sacramento, Calif.; University of Michigan, Homeopathic School, Ann Arbor, 1883; aged 67; died at his home, March 29, from heart disease.

Died in the Service
IN FRANCE
Lieut. Julian Neal Dow, M. R. C.,
U. S. Army, 1894-1918

James H. Noyes, Ogden, Iowa; Columbia University, College of Physicians and Surgeons, 1861; aged 81; died at his home, January 31, from senile debility.

Frank Mortimer Gier, Hillsdale, Mich.; University of Michigan Medical School, Ann Arbor, 1884; aged 59; died at his home, March 28, from uremia.

Asa F. Goodrich, St. Paul; Hahnemann Medical College and Hospital, Philadelphia, 1889; aged 52; died at his home, March 29, from pneumonia.

John E. Meadors, Mahon, La.; Medical College of Georgia, Augusta, 1857; aged 82; died at the home of his daughter in Homer, La., March 25.

Thomas S. Parker, Cohoes, N. Y. (license, New York, years of practice); aged 80; died at Cohoes (N. Y.) Hospital, March 19.

William Henry Hills, Chelmsford, Mass.; Harvard University Medical School, Boston, 1869; aged 77; died in Florida, March 30.

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

NOSTRUMS IN RETROSPECT

A Review of Worthless or Unscientific Proprietary Mixtures Previously Criticized

[Foreword.—The article that follows is the ninth[1] of a series written for the purpose of reviewing the findings of the Council on Pharmacy and Chemistry on certain unscientific or worthless proprietary mixtures advertised to physicians. Although the preparations taken up in this series have been dealt with in previous reports, the fact that they are still widely advertised and prescribed indicates the need of further publicity. The writer of the series is thoroughly conversant with the work of the Council on Pharmacy and Chemistry and can speak authoritatively on questions dealing with the actions of drugs in the treatment of disease.]

[Article IX]

NEUROSINE AND THE ORIGINAL PACKAGE EVIL

By S. Q. Lapius, M.D.

We called attention recently to the skill which the nostrum vender displays in avoiding the particular thorn that pricks him, and his development of the art of impressively saying "Nothing in General," as exemplified in the advertisements of Fellows' Syrup. Nostrum sellers are more canny than original and when once an idea finds lodgment with one of them, it is made to serve many masters. Formerly exploiters of either vicious or worthless nostrums were wont to boast that their preparations were exploited in a "strictly ethical manner." Recent perusal of as choice a lot of advertisements as can be found in the most degraded of medical journals failed to disclose this claim in a single instance, although the claim that a preparation is "advertised *only* to physicians" is still common.

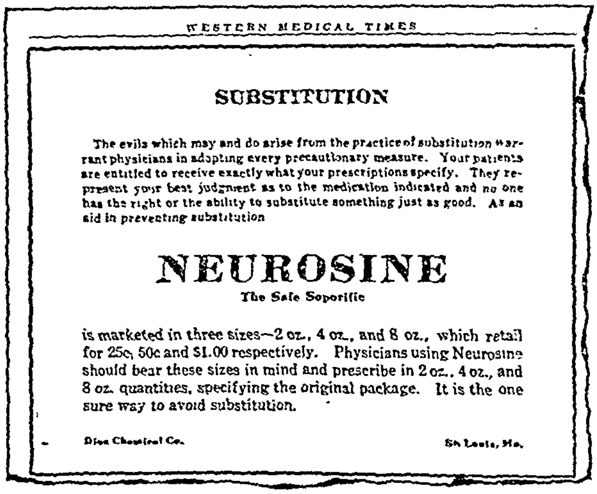
The advertisement of "Neurosine," which we reproduce, was the first one which came to our attention when we searched through some medical journals for one that would illustrate a discussion of the "original package" evil. This is the only reason for selecting Neurosine rather than another. Such half-page advertisement and others of similar size in various medical journals cost a good deal of money and they presuppose that the Dios Chemical Company is interested in having original bottles of Neurosine dispensed every time that that nostrum is prescribed.

Why should the firm have any such deep interest in seeing that an original *bottle* gets to the patient? Why should it be necessary to do anything more than see that the genuine *mixture* reaches the patient? Does it seem within the bounds of reason that substitution is so commonly practiced by pharmacists that this firm must go to large expense to prevent the substitution of spurious mixtures for its product? Is dishonesty the rule among pharmacists? Common sense rejects the plea as placing too great a strain on one's credulity. Obviously, then, the advertisement does not tell the whole truth, though it does indeed tell exactly what the nostrum maker wishes to have *done*, that is, to have only *original bottles* dispensed when physicians prescribe that nostrum. The fact we have; the reason is not far to seek.

When the pharmacist puts up an ordinary, nonproprietary prescription, the patient gets no clue from the package as to the nature of the prescription employed. But when an original bottle of Neurosine is dispensed, even though the pharmacist puts his own prescription label on it, the patient sees the difference at once and knows just why the usual prescription bottle was not employed. He also knows that he can get the medicine with its original wrapper or label by merely showing the bottle to the druggist, for the words "Neurosine" and "Dios Chemical Co.," are blown in the glass. Here, then, may be a plausible reason for desiring that only original bottles be dispensed.

You may ask: "What difference does it make if the patient does learn the name of the nostrum, he must go to his physician for advice concerning its use?" Having learned the name of the remedy that has been prescribed for sleeplessness, let us say, he proceeds to use it whenever he imagines that he needs it, and that need, real or imaginary, has a way of increasing in frequency. As a result, the patient takes far more Neurosine than the physician would think of permitting if the matter had not passed entirely beyond his control.

Not only has the patient acquired a dangerous habit of self-prescribing, but he takes especial delight in recommending his favorite remedy to friends whose symptoms, real and imaginary, seem to resemble his own. This offers him an opportunity to prescribe with an air of authority. It was prescribed for him by Dr. Blank, and it gave relief, *ergo* it may be depended on to give relief to others! Thus is the basis laid for its general use by the laity, when this process is multiplied sufficiently. The statement is susceptible of easy proof by any one who cares to investigate the matter for himself. There is probably no physician worthy of the name who will attempt to deny that the promiscuous use of hypnotics and narcotics is dangerous, and certainly no careful physician will deliberately place a narcotic in the hands of patients to be used freely and without control.



WESTERN MEDICAL TIMES

SUBSTITUTION

The evils which may and do arise from the practice of substitution warrant physicians in adopting every precautionary measure. Your patients are entitled to receive exactly what your prescriptions specify. They represent your best judgment as to the medication indicated and no one has the right or the ability to substitute something just as good. As an aid in preventing substitution

NEUROSINE

The Safe Soporific

is marketed in three sizes—2 oz., 4 oz., and 8 oz., which retail for 25c, 50c and $1.00 respectively. Physicians using Neurosine should bear these sizes in mind and prescribe in 2 oz., 4 oz., and 8 oz. quantities, specifying the original package. It is the one sure way to avoid substitution.

Dios Chemical Co. St. Louis, Mo.

Since we have selected Neurosine at random, so far as this particular discussion is concerned, it is worth while to inquire into its composition, the claims that have been made for it and the evidence, if any exists, for or against its therapeutic value. Even the most active of hypnotics are worse than useless if they are inferior to other readily available hypnotics, or if they have undesired side-actions that outweigh any advantages that they might otherwise have.

The Council on Pharmacy and Chemistry investigated the literature relating to Neurosine and published its report in The Journal, Jan. 9, 1915, p. 165. According to this report *the manufacturers of Neurosine claimed that each fluidounce* contained:

Bromid of potassium, C. P.	40	grains
Bromid of sodium, C. P.	40	grains
Bromid of ammonium, C. P.	40	grains
Bromid of zinc	1	grain
Extract lupulin	32	grains
Cascara sagrada, fl. ex.	40	minims
Extract henbane	0.075	grain
Extract belladonna	0.075	grain
Extract cannabis indica	0.60	grain
Oil bitter almonds	0.60	grain
Aromatic elixir		

---

[1] The previous articles of the series are "Bell-ans," The Journal, Nov. 24, 1917; "Anasarcin and Anedemin," Dec. 8, 1917; "Pepto-Mangan," Dec. 29, 1917; "Cactina Pillets," Jan. 19, 1918; "Ammonol and Phenalgin," Feb. 2, 1918; "Fellows' Syrup and Other Preparations of the Hypophosphites," Feb. 16, 1918; "Shotgun Nostrums," March 2, 1918; "Tyree's Antiseptic and Aseptinol," March 30, 1918.

This chemical blunderbuss was recommended for use in insomnia, hysteria, neurasthenia, migraine, neuralgia, delirium tremens, epilepsy and many other conditions. Also it was called an ideal calmative for children suffering from chorea, the exploiters claiming that "All authorities recommend the bromids, hyoscyamus and cannabis indica in this disease." Oliver T. Osborne, Professor of Therapeutics in Yale Medical School, does not mention one of these three drugs in his discussion of the Medicinal Treatment of Chorea, in the "Handbook of Therapy," though he quotes several authorities in this article. Indeed he does not mention one of the ten drugs included in the above formula of Neurosine in connection with the treatment of this disease. It is a curious fact that Osborne gives the greatest prominence to the use of that drug which is claimed to be wanting in the formula of Neurosine, viz., hydrated chloral.

Perhaps you may have seen temporary relief follow the administration of Neurosine in chorea, and may argue that theorizing is of little value in the face of personal experience. We shall not deny that some may have had that experience, for Osborne calls attention to the fact that the success of any medicinal treatment must be judged in the light of the fact that chorea is self-limited, and the intensity of the symptoms will abate in from two to four weeks. In view of this we would hardly dispute the claim that one may administer narcotics, such as those contained in Neurosine, and the symptoms of chorea may abate in spite of such mistreatment. In all the years that Neurosine has been exploited to physicians with such remarkable claims, we have never seen a report of a careful clinical study in which the product has been used under the conditions which scientific investigation demands. Would you prescribe any nonproprietary preparation which had never been studied clinically, if a horse-shoer or grocer's boy told you it would cure epilepsy or malaria?

According to an editorial note appended to the report of the Council on Neurosine the Dios Chemical Company consisted at that time (1915) of J. H. Chambers, his wife and two sons. It appeared that Chambers never claimed to have any special knowledge of chemistry, pharmacy or medicine, yet we find that he arrogated to himself or to his employees the right to offer therapeutic advice to the medical profession, and even to direct them how they should prescribe a given mixture.

We sometimes fail to see the forest because of the trees. It may help us to obtain a better perspective, in a problem that concerns us intimately, by resorting to a hypothetical case, if a close analogy is maintained. In order that we may see ourselves as others see us in such a situation let us consider the following imaginary case: You become involved in a lawsuit in which an effort is made to deprive you of your property and your liberty. You seek what you had reason to believe was competent legal advice but nevertheless you lose your case and find yourself deprived of your property and your liberty. Now let us suppose further that you discover, when too late to permit you to correct your mistake, that your legal adviser (we can hardly call such a man a lawyer) had been acting all along under the guidance of a plumber who made no pretense of knowing anything about law. How would you feel regarding that pretended lawyer? Would you feel that you had been treated fairly? Would you feel disposed to speak with all charity of him, to recommend him to those in need of legal advice?

You would probably feel toward such a lawyer as patients must feel toward physicians who prescribe proprietary nostrums based on information and advice offered by those who, though without any special knowledge of chemistry, pharmacy or medicine, will be benefited financially if their information and advise are accepted and acted on.

Plauge.—There were thirty epidemics of bubonic plague between the eleventh and fifteenth centuries. The worst one in Europe was in the fourteenth century. The population of Europe was about 105,000,000 in 1334; the "Black Death" started from China. It killed nearly 24 per cent. of the people in Europe—that is, almost every fourth person was doomed. It is said to have killed half the population of Italy.

A METHOD OF FACILITATING THE SERUM DIAGNOSIS OF SYPHILIS UNDER WAR CONDITIONS

To the Editor:—Supplementary to the paper with this title, published last week, p. 1157, permit me to add the following suggestion: According to Rhamy (The Journal, Nov. 17, 1917, p. 1728), guinea-pig complement can be preserved in a mixture consisting of 1 part of the fresh guinea-pig serum and 1.5 parts of a 10 per cent. sodium acetate solution in 0.9 per cent. saline for a considerable length of time at room temperature, and the acetate does not interfere with the fixation reaction. The writer has confirmed Rhamy's statement and can add that the same is true of human complement. By mixing fresh serum with the acetate saline solution in equal parts the complement remains perfectly active at room temperature for at least five days, and the results of the tests made with the acetated serums are no different from those obtained with the same specimens in fresh state without the acetate. It is advisable, therefore, to preserve a specimen intended for transportation for some distance in a sodium acetate saline solution while the specimen is perfectly fresh. Thus, the serum may be mixed with an equal part of the 10 per cent. sodium acetate saline solution and 0.2 to 0.4 c.c. of the mixture used for the test, this amount representing 0.1 to 0.2 c.c. of the pure serum.

Sodium acetate may also be added directly to the blood while the patient is being bled for the test. A sterile stock solution containing 50 per cent. sodium acetate and 0.9 per cent. sodium chlorid is prepared, and when bleeding the patient, 0.5 c.c. of the solution is mixed with 4.5 c.c. of the blood in a graduated tube (or any plain tube with a mark for 5 c.c.). The separation of serum is slow and may be hastened by gently breaking up the clot. For the test 0.1 to 0.2 c.c. of the serum is used.

Another important point is the fact that the test can be carried out at any temperature between 21 C. (70 F.) and 37 C. (98.6 F.), provided that the mixture be allowed to stand for two hours at 21 to 25 C. (70 to 77 F.) and one hour at 30 C. (86 F.). During the warm seasons or in subtropical or tropical countries, therefore, no special incubator is required, although an incubator is absolutely necessary when the temperature in the laboratory falls below 21 C. It may be mentioned that a strongly positive serum completes the fixation of complement within twenty minutes at the temperature of 21 C., or that of the ordinary laboratory room. It is for weaker reactions that the time of standing for two hours is being allowed. As stated above only one hour is sufficient when the temperature is about 30 C. Fluctuation in temperature within the minimal and the optimal points during the incubation is of no consequence.

Hideyo Noguchi, M.D., New York.

THE OWEN-DYER BILLS FOR INCREASED RANK OF MEDICAL OFFICERS

To the Editor:—The bills now pending before Congress for increased rank and authority for the medical officers of our Army are of as grave importance as any measures that have been presented since the American nation entered the present war, for on their adoption or rejection may depend the final issues of the conflict, especially if the war is greatly prolonged. When it is remembered that the Medical Department of the Army has to combat a foe that in all the great wars of history, excepting the Russo-Japanese, has caused 80 per cent. of the entire mortality—never less than four times, and often twenty times, as many as the artillery, infantry, shells and all other methods of physical destruction combined—then the responsibility and importance of the medical officer in war will be appreciated.

The department that he represents has never had the necessary authority to enable it to reduce this frightful 80 per cent. mortality to a minimum, and without in any way interfering with the strategy or military operations of the war.

The Medical Department of our Army is founded on the traditions of the British medical department of 1776, when preventive medicine was an unknown science and when the duty of the medical officer was to cure disease, instead of preventing it—of locking the stable after the theft has been committed.

Our medical officers have never had the necessary rank and authority to prevent the development of epidemics and other diseases that have caused the frightful mortality incident to war. Witness the records of the Spanish-American War in Cuba and Porto Rico and in the Philippines, which practically typify the conditions that existed in the Boer War in South Africa, in our own Civil War of 1861-1864, in the Russo-Turkish War, and in the British campaign in the Crimea.

The Porto-Rican expedition in the opera bouffe performance known as the Spanish War may be taken as an example, for nowhere in history is there found a more illuminating instance, a graver lesson, or a more terrible warning than is there portrayed. For our country, it is the Mene, Mene, Tekel Upharsin, the handwriting on the wall, so easily decipherable that he who runs may read; and yet, in the glory of victory and the enjoyment of prosperity, its lesson has passed unheeded.

The story of the expedition is brief. About 20,000 American troops landed in Porto Rico, while the Spanish on the island numbered about 17,000. Several skirmishes occurred, in which, according to the Surgeon-General's report, three men were lost from the casualties of war. The object of the war, the breaking of the chains of Spanish despotism and spoliation, which for centuries had held a race in shameful moral serfdom, was soon accomplished, and the war—from the strictly military standpoint—was over. From our first arrival, the natives of the island welcomed our battalions with vivas of applause, strewing our advancing march with flowers, and their masses were prepared joyfully to second our efforts for their complete emancipation.

That is the beautiful story history presents. Lest we forget as a nation, and lie supine in the easy content of this picture, let me invite attention for a moment to a further study of the report of the Surgeon-General for that war. It states that although only three men fell from the casualties of battle during that entire campaign, 262, or nearly 100 times as many, died from preventable causes. It fails, however, to state that the number of hospital admissions nearly equaled the entire strength of the invading army, and that the camps of the army from one end of the island to the other, were pestiferous hotbeds of disease before they had been occupied a month, so that, had the bugle sounded for action, only a small percentage of the units would have been in a condition to respond to the call. Nor was this state of affairs confined to Porto Rico. In the invading armies of the Philippines and Cuba the same conditions prevailed.

The official figures, as shown on the following table, were furnished me by the Surgeon-General of the Army, Oct. 10, 1905, and cover the vital statistics of the United States military expeditions for the year 1898:

	Deaths from Battle Casualties	Deaths from Disease
In the Philippine Islands	17	203
In Porto Rico	3	262
In Cuba	273	567
In the U. S. home camps, etc	...	2,649
Total deaths	293	3,681

or about one from casualties to thirteen from disease.

The report further shows that, while the average mean strength of the army enlisted for the Spanish War was about 170,000, the total number of admissions to the hospitals, Sept. 10, 1898, was more than 158,000, or 90 per cent. This in a war of less than three months' duration, and in which more than three fourths of its soldiers never left the camps of their native land.

The Japanese army for the same period had about 4 per cent. hospital admissions, or one twenty-second as many. The vast difference in favor of the Japanese figures illustrates the value of a medical and sanitary department properly equipped to enforce practical sanitation, dietary and other preventive measures.

The greatest tragedy of war lies, not in the battle field, but in the failure of a government to protect its guardians from preventable disease, thereby immeasurably increasing the suffering and mortality incident to it. This can be largely prevented by giving the medical officer authority to enforce sanitation and supervisory control over the ration of the troops.

Every death from preventable disease is an insult to the intelligence of the age. If it occurs in the army, it becomes a governmental crime. The state deprives the soldier of his liberty, prescribes his hours of rest, his exercise, equipment, dress, diet and the locality in which he shall reside, and in the hour of danger expects him, if necessary, to lay down his life in defense of its honor. It should, therefore, give him the best sanitation and the best medical supervision the science of the age can devise, be it Japanese or Patagonian—a fact of which Congress will do well to take cognizance at the earliest moment. For, just as surely as the engineer who disregards the signals, or the train dispatcher who gives wrong orders, is legally responsible for the loss of human life in the wreck that follows, so Congress, or the wretched medical system of our Army, is responsible for the thousands of soldiers' lives needlessly, criminally sacrificed—not on the glorious field of battle, but in diseased camps—from preventable causes.

Herbert Spencer, in his "Synthetic Philosophy," refers to "the ill treatment accorded the medical officers of the English army as a late survival of the days of feudalism, and contempt for the purely scientific."

If wars are inevitable, and the slaughter of men must go on (and I believe wars are inevitable and that most of them are ultimately beneficial), then let our men be killed legitimately, on the field, fighting for the stake at issue, not dropped by the wayside from preventable disease as we did in the Spanish-American War—1,300 for every hundred that died in action. It is for the 1,300 brave fellows that are needlessly sacrificed, never for the hundred that fall gallantly fighting, that I offer my prayer.

I believe that if our Medical Department, in the Spanish-American War, had been systematized, with sufficient numbers, with supervisory control over the ration, and with power to enforce sanitary and hygienic relations, the units of our Army would have returned to their homes at the close of the campaign in better physical condition than when they entered it, improved by their summer outing.

An army might be suffering from diarrhea or slight intestinal catarrh, due to change of water, of ration or of climate (and I have seen 90 per cent. of an entire command in this condition at one time), compelled to live on a diet of pork and beans and fermented canned foods that in six weeks prostrated 50 per cent. of its number with intestinal diseases and sent 3,000 to their everlasting homes, to say nothing of the enormous number invalided, and the 75,000 pension claims that followed as the result. Until the men were admitted to hospital wards, the medical officer had no authority even to order a rice diet, which would have prevented the men from becoming invalided. This was one of the principal causes that brought our Army of 170,000 men in the Spanish War almost to its knees in three months, and sent the survivors home in the shrunken and shriveled condition that many of us still remember.

In all the wars in which the United States has engaged, disease has been responsible for more than 70 per cent. of the mortality, more than half of which could have easily been prevented, had the Medical Department been properly empowered to meet its obligations. Preventable disease, more than wounds, swells the pension list. Statistics of the Pension Office prove that if this unnecessary loss had been avoided, the saving in pensions alone, in every war in which America has participated, would have paid the cost of the resulting war every twenty-five years. Aside from the sorrow of the homes made desolate, consider the economic value of the 70 per cent. of lives needlessly sacrificed, that might be saved as breadwinners in industrial pursuits.

In an address delivered before the International Congress of Military Surgeons in 1904, after my return from the Russo-Japanese War, I said: "Perhaps the day is not distant when another summons will come to join the Army of the Republic, when the first call may be, not as in the Civil War for 75,000 men, nor as in the Spanish War for 250,000, but when, more likely it will be for a round half million, to be followed possibly by another of equal number. And the question will be asked by the young patriot of that day, not *who* the enemy is he is to meet—No, the American boy is *not* built that way—but he will demand to know what measures have been taken to insure him against the silent enemy who kills the 80 per cent. And when he learns the same prehistoric regulations as to sanitation and protection against this foe are in force as they were in 1904, will he respond to his country's call? Yes, he will, for that is the way the American boy is built. And he will follow, as did his forebears, in their footsteps, and he will fall by the wayside as they did before. And history will record another crime."

> We see by the light of thousands of years,
>   And the knowledge of millions of men,
> The lessons they learned through blood and in tears
>   Are ours for the reading, and then
> We sneer at their errors and follies and dreams,
>   Their frail idols of mind and of stone,
> And call ourselves wiser, forgetting, it seems,
>   That the future may laugh at our own.

Let Congress give the medical officer rank and authority in all matters appertaining to sanitation and preventable disease and supervision over the ration, when such authority will not interfere with the strategy of the commanding officer of the line, and then, if serious epidemics or other preventable diseases occur, have him courtmartialed and cashiered from the Army, as though he were a traitor and a spy.

Louis Livingston Seaman, M.D., LL.B., F.R.G.S.,
New York.
Late Surgeon-Major, U. S. Volunteer Engineers.

"BREVITY IS THE SOUL OF WIT"

To the Editor:—I have now been a reader of your valuable paper for more than a year, and do not see how I can possibly do without my weekly copy. The thing that kills the British medical journals is the length of their articles. It almost seems that every writer makes it his business to make his articles as long as he possibly can instead of the reverse. I trust, therefore, that you will not allow that vice to creep into The Journal. A busy man has no time to be bored with such long articles. I thought the article on "The Treatment of Hookworm Infection," published in The Journal, February 23, was rather long, and contained tables that might have been eliminated with a summary.

W. H. Haupt, M.D., Caterham, Surrey, England.

TOXICITY OF ARSPHENAMIN (SALVARSAN): REPORT OF CASES

To the Editor:—Having read a report by Dr. James C. Sargent of Milwaukee on five cases of unusual toxicity resulting from administration of the new American made salvarsan, I am constrained to report three cases, believing that this information should be given to the medical profession.

A man, aged 38, suffering from the secondary stage of syphilis, who had had three weekly 0.6 gm. doses of diarsenol with no toxic reactions following, reported for his fourth treatment. The first obtainable American made salvarsan had just reached us, and a dose of this was given after being mixed in the following manner: First the ampule was dissolved in 90 c.c. of hot sterile freshly distilled water, and sufficient cool freshly distilled water was added to bring the amount up to a 200 c.c. bulk. Freshly prepared 15 per cent. sodium hydroxid was added drop by drop, the solution being stirred constantly, until the precipitate was redissolved. The solution was given by the single tube gravity apparatus method into a vein at the bend of the elbow, this method having been used by us more than 400 times without a single bad result. Before one half of this solution had been given, the patient began to complain of severe pains in various parts of his body. He became prostrated, his pulse rapid and weak, and cold perspiration stood out over him. The patient became nauseated but did not vomit. The solution was discontinued, and blankets and hot water bottles were applied. After about three hours the patient felt almost normal but during this period he complained of more or less pain and showed signs of shock.

The second case was that of a man, aged 36, with an old long standing case of syphilis who was undergoing a series of arsphenamin treatments. He had had three weekly doses of diarsenol without any reaction. He was given a 0.6 gm. dose of American made salvarsan made up as in the preceding case. Just prior to the discontinuance of the injection of the full dose this patient began to complain of pains in various parts of his body, his face and eyes became intensely injected, and his face was slightly swollen. He was decidedly nauseated, but did not vomit. After about an hour he felt able to go home.

The third case was that of a boy, aged 17, who was being treated in the secondary stage of syphilis and had had two weekly 0.5 gm. doses of diarsenol with no reaction following. He was given a 0.5 gm. dose of the American made salvarsan one week following his second dose of diarsenol. Throughout the injection of the solution the patient felt well. About one minute after the discontinuance of the injection and while the patient was yet on the treatment table, his face flushed suddenly, and the eyelids, lips and tongue swelled to huge proportions. The tongue was so thick that he could scarcely protrude it. The eyes were injected, and he vomited freely. He complained of intense pain in various parts of the body, especially through the abdomen. The pulse was very rapid and weak. Immediately a 15 minim dose of epinephrin solution was given hypodermically. This dose was repeated in fifteen minutes. He was put to bed in the hospital and external heat applied. The swelling of the tongue, eyelids and face gradually subsided, and after about four hours had practically disappeared. The patient was able to leave the hospital in about six hours.

These three doses of American made salvarsan were the first doses that had been used in this hospital and, because of these reactions following their administration, we decided not to give the fourth dose, so returned the remainder of the shipment to the Farbwerke-Hoechst Company. They have acknowledged receipt of the returned shipment and have written us that they expect to make further investigations of the lot in an effort to determine where the difficulty is. They report that both biologic and chemical controls were perfectly satisfactory before releasing the salvarsan.

J. D. Willis, M.D.,
Lewis-Gale Hospital, Roanoke, Va.

[Comment.—The publication of the report by Dr. Sargent stimulated a number of physicians to write to The Journal on this subject. Mr. Metz, the manufacturer of the salvarsan brand of arsphenamin, in protesting against its publication said that "the lot from which Dr. Sargent's ampules were taken met every requirement of the standard set for salvarsan," and intimated further that the reactions were "due to faulty technic, unsatisfactory conditions of ingredients used in preparing the salvarsan solution, or condition of his subjects." Such experiences as those of Drs. Sargent and Willis are not unusual, but should be reported. It is, of course, well known that untoward results followed the use of the old salvarsan—that made in Germany. With the old preparation, as well as with the new, reactions occurred and were probably due to various causes: sometimes to faulty preparations, sometimes to the deterioration of certain ampules of a batch, sometimes to idiosyncrasy of the patient, and sometimes to faulty technic of preparation or injection. There is no reason to believe that the arsphenamin made in this country is more toxic or less satisfactory than that formerly imported from abroad. The present provisions for the control and testing of the output of arsphenamin in this country appear to be quite satisfactory: The manufacturer is required, not only to test his product himself, but also to submit a certain percentage of each batch to the Hygienic Laboratory of the Public Health Service for a second test. Physicians may use the product with confidence, but if untoward results occur with any ampule of any preparation, the results should be reported in order that knowledge of the possibilities, improvements in technic or in handling a preparation of the drug may result. Let it be remembered that injection into a vein, no matter what the substance injected, is a serious procedure. When arsphenamin is the substance used, it involves not only the hazards of intravenous therapy but also the hazard of a potent drug. However, we repeat, when used with a complete knowledge of the method and the possibilities, there should be no lack of confidence in any of the federal licensed products.—Ed.]

RADIUM TREATMENT OF CANCER OF THE LIP

To the Editor:—In the article by Dr. Henry H. Janeway on the treatment of cancer of the lip by radium (The Journal, April 13, p. 1051), he describes the method of treating cancer of the lip by emanation of radium in glass tubes instead of radium element in flat applicators and after reporting his splendid results states: "The superior adaptability of radium emanation for the treatment of cancer makes the use of the element itself obsolete, and for the vast majority of cases it is inefficient." I believe the use of radium element of the required strength scattered over a flat applicator 1 c.c. square is much more accurate and scientific than the use of emanation in glass tubes in treating lip cancer, as the flat applicator fits evenly over the region on the lip. It gives off a uniform quantity of rays and dose from different applicators so that results can be duplicated in other cases and by other persons. This can not be said of emanation used in glass tubes because even if a certain strength in millicuries is in the tube at the time of testing, the tube deteriorates rapidly and loses its strength. In a few hours, after a tube is tested the physician does not know the strength he is using. Moreover, the glass of different tubes varies greatly in thickness and further complicates the administration of a definite dose.

J. N. Scott, M.D., Kansas City, Mo.

HERPES ZOSTER AND CHICKENPOX

To the Editor:—The report of cases showing the relation between herpes zoster and chickenpox made by Drs. Goldberg and Francis in the April 13 number of The Journal recalled to my mind an experience I recently had which showed such a relation. On Feb. 15, 1918, a young lady came to my office with a typical case of herpes zoster following the course of the superficial nerves of the cervical plexus. March 3, I was called to see the patient's younger brother and found a well developed case of chickenpox. During February there were only fourteen cases of chickenpox reported in the city. Thirteen of these were in the extreme other end of town and one was about four blocks distant from my patient, and the child in that case went to another school. I am not able to find that my patient was ever exposed to chickenpox.

A. G. Hough, M.D., Madison, Wis.

"TONICS AND SEDATIVES"

To the Editor:—I wonder if any of your feminine readers have thought of cutting out "Tonics and Sedatives," binding them in loose leaf form and sending them to the Army hospitals. I have been doing this for two years, and they tell me the soldiers enjoy them; the heading is so appreciative too. I hope that others of your readers will follow this suggestion.

Helen Bates, Summit, N. J.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

ENLISTMENT IN M. R. C.—COMMUTATION FOR OFFICERS

To the Editor:—1. I am anxious to do my full part in this war. I note the call for 5,000 doctors. I am one of two shop surgeons looking after some 1,500 men. The other is under draft age, though claiming exemption on financial grounds. What is my duty as appears to one who has a view of the whole situation? 2. Is the enlistment period in the Naval Reserve three years, or for the length of the war? 3. What amount will be added to the salary of a first lieutenant if the maintenance bill is passed?

M. D., Omaha.

Answer.—1. The Surgeon-General has asked each physician to determine for himself the question as to whether or not it is his duty to enlist. In paragraph 5 of his call to the American Medical Association he says:

> It is earnestly desired that the interests of the civil communities be conserved as far as possible and that no enlistments in the Medical Reserve Corps be made that would work serious hardship upon any community, manufacturing concern or other civil activity by taking from such community, manufacturing concern or other civil activity, physicians whose services are needed for the efficient and competent care of the civil population or the employees of large concerns.

2. The physician who enlists in the Naval Reserve obligates himself, and may be immediately ordered, to service in the Navy throughout the war or during the existence of a national emergency declared by the President, should either arise during his term of enlistment. A member enrolls or reenrolls for a term of four years. In time of peace, and when no national emergency exists, a member may be discharged on his own request.

3. An item on this subject appears under Current Comment, this issue, p. 1232.

THE ACCEPTANCE OF COMMISSIONS

To the Editor:—In Current Comment (The Journal, April 13, 1918, p. 1098) I noticed a statement that there are approximately 18,300 members in the Medical Corps and about 1,500 men who have been offered commissions but have not yet accepted. Will you kindly tell me what I may imply by this statement, "commissions offered, but not yet accepted"? I would appreciate very much if you will communicate with me at your earliest convenience. I am contemplating going into the service, and want to get as much information about this matter as possible.

William S. Keller, M.D., Cincinnati.

Answer.—Before a commission is in effect it must be accepted in writing, and an oath of allegiance taken. Many have not done this, some not realizing its necessity, others through neglect, or because they want to back out of their contract. It is needless to say that such action is not creditable. If a man makes application for a commission in the Medical Reserve Corps and goes through all the preliminaries, including examination, he to all intents and purposes makes a contract to accept the commission if it is awarded him.

NO NATIONAL LICENSURE FOR RESERVE OFFICERS

To the Editor:—Does a physician, after being discharged from serving in the Medical Reserve Corps, have the privilege of practicing in any state in the Union?

W. H. H.

Answer—No.

To Send Serum by Mail for Wassermann Test.—R. Tsuneoka and T. Yotsumiya relate that a safe and certain means for sending serum to a laboratory for testing is to soak up the serum into blotting paper and allow the paper to dry in a dark room at a temperature of from 80 to 86 F. Serum thus dried into the blotting paper can be kept without deterioration for five or six days. When the test is to be applied the serum is dissolved out of the paper by soaking in sterile saline and squeezing the paper. An abstract of their article is given in the *China Medical Journal*, which publishes regularly, in pamphlet form, English abstracts of the leading articles in the current Japanese medical periodicals (Presbyterian Mission Press, Shanghai).

Indiana January Examination

Dr. W. T. Gott, secretary of the Indiana State Board of Medical Registration and Examination, reports the written examination held at Indianapolis, Jan. 10-12, 1918. The examination covered 16 subjects and included 100 questions. An average of 75 per cent. was required to pass. Of the 8 candidates examined, 4, including 1 osteopath, passed and 3 failed. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
Indiana Medical College (Purdue University)	(1906)	83.5
Indiana University	(1917) 88.2; (1918)*	80.8
FAILED		
Louisville National Medical College	(1909)	84.7†
Meharry Medical College	(1916) 71.4,	81.2†
National University, Athens	(1912)	‡

* Diploma and license withheld until June, 1918, to complete time credits.

† Fell below 75 per cent. in three subjects.

‡ This candidate's papers were not graded because he "was detected in flagrantly violating rules governing conduct of examination."

New Mexico January Examination

Dr. R. K. McClanahan, secretary of the New Mexico Board of Health and Medical Examiners, reports the written examination held at Sante Fe, Jan. 14-15, 1918. The examination covered 11 subjects and included 100 questions. An average of 75 per cent. was required to pass. Two candidates were examined, both of whom passed. Seven candidates were licensed on credentials, and 1 candidate was licensed through reciprocity. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
Loyola University	(1916)	75
Leonard Medical School	(1903)	75

College	Year Grad.	Total No. Licensed
LICENSED ON CREDENTIALS		
George Washington University	(1907)	1
Rush Medical College	(1885)	1
Medical School of Maine	(1892)	1
College of Physicians and Surgeons, Baltimore	(1880)	1
Detroit College of Medicine and Surgery	(1917)	1
Memphis Hospital Medical College	(1913)	1
Vanderbilt University	(1913)	1

College	Year Grad.	Reciprocity with
LICENSED THROUGH RECIPROCITY		
University of Oklahoma	(1914)	Oklahoma

New York Report

Mr. George M. Wiley, director, Examinations and Inspections Division, reports that 10 candidates were licensed by reciprocity from Jan. 7 to Feb. 27, 1918. The following colleges were represented:

College	Year Grad.	Reciprocity with
LICENSED THROUGH RECIPROCITY		
Georgetown University	(1911)	Delaware
University of Maryland	(1906)	New Jersey
Hamline University	(1907)	Minnesota
Columbia University (1909) Pennsylvania;	(1910)	New Jersey
N. Y. Homeo. Med. Coll. and Flower Hosp. (1913)	(1914)	Delaware
Jefferson Medical College (1902) New Jersey;	(1903)	Penna.
University of Pennsylvania	(1901)	Penna.

North Dakota January Examination

Dr. G. M. Williamson, secretary of the North Dakota State Board of Medical Examiners, reports the oral, practical and written examination held at Grand Forks, Jan. 1-4, 1918. The examination covered 13 subjects and included 110 questions. An average of 75 per cent. was required to pass. Of the 6 candidates examined, 4 passed and 2 failed. Three candidates were licensed through reciprocity. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
Rush Medical College	(1916)	82
Keokuk Medical College, Coll. of Phys. and Surg.	(1905)	*
Johns Hopkins University	(1916)	85.3
University of Michigan Medical School	(1904)	*
FAILED		
Bennett Medical College	(1908)	68
Chicago College of Medicine and Surgery	(1908)	70

College	Year Grad.	Reciprocity with
LICENSED THROUGH RECIPROCITY		
Baltimore Medical College	(1906)	Illinois
Hamline University	(1903)	Minnesota
John A. Creighton Medical College	(1905)	Nebraska

* No grade given.

Ohio Reciprocity Report

Dr. Herbert M. Platter, secretary of the Ohio State Medical Board, reports that 13 candidates were licensed through reciprocity at the meeting held Jan. 2, 1918. The following colleges were represented:

College	Year Grad.	Reciprocity with
LICENSED THROUGH RECIPROCITY		
Howard University	(1903)	Alabama
Bennett College of Eclectic Med. and Surg.	(1906)	Penna.
College of Physicians and Surgeons, Chicago	(1903)	Illinois
Hahnemann Med. Coll. and Hosp. of Chicago	(1873)	Illinois
Drake University	(1907)	Iowa
College of Phys. and Surgs., Baltimore	(1901)	W. Virginia
Johns Hopkins University	(1914)	Maryland
University of Michigan Medical School	(1908)	Michigan

South Dakota January Examination

Dr. Park B. Jenkins, secretary of the South Dakota State Board of Health and Medical Examiners, reports the practical and written examination held at Pierre, Jan. 8-10, 1918. The examination covered 15 subjects and included 125 questions. An average of 75 per cent. was required to pass. Seven candidates were examined, all of whom passed. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
College of Physicians and Surgeons, Chicago	(1900)	78.8
Northwestern University	(1915) 88.6,	89.2
Keokuk Medical College, Coll. of Phys. and Surgs.	(1907)	85.6
St. Louis College of Physicians and Surgeons	(1915)	79.3
Hahnemann Medical College of Philadelphia	(1876)	83.4
Jefferson Medical College	(1917)	86.2

Utah January Report

Dr. G. F. Harding, corresponding secretary of the Utah State Board of Medical Examiners, reports that at the meeting held at Salt Lake City, Jan. 7-8, 1918, four candidates were licensed through reciprocity. The following colleges were represented:

College	Year Grad.	Reciprocity with
LICENSED THROUGH RECIPROCITY		
Denver and Gross College of Medicine	(1905)	Colorado
Hahnemann Medical College and Hospital of Chicago	(1914)	Illinois
University of Illinois	(1916)	Ohio
Michigan College of Medicine and Surgery	(1904)	Michigan

Wisconsin February Report

Dr. J. M. Dodd, secretary of the Wisconsin State Board of Medical Examiners, reports that 3 candidates were licensed through reciprocity at the meeting held at Chicago, Feb. 4-5, 1918. The following colleges were represented:

College	Year Grad.	Reciprocity with
LICENSED THROUGH RECIPROCITY		
College of Physicians and Surgeons, Chicago	(1906)	Illinois
University of Illinois	(1914)	Illinois
Fordham University	(1915)	New York

Social Medicine, Medical Economics and Miscellany

Undernutrition Among Schoolchildren

As a result of the report of the bureau of child hygiene to the effect that between 12 and 15 per cent. of the schoolchildren of the city are underfed, Frank A. Manny undertook a detailed and intimate study of health and nutrition conditions among two schools in the Grammercy district. The children were classified on the basis of the Dumferline scale, which places each child in one of four nutrition grades: (1) superior condition; (2) passable condition; (3) requiring supervision; (4) requiring medical treatment. Of 2,535 children examined, one third of the total were in each of the first two grades, and the remaining third was divided between the other two. There were found three distinct height and weight measurements corresponding to the three larger nutrition grades, Grades 3 and 4 being taken together and containing one third of the whole. The average of the low nutrition cases fell below the passable group to about the same extent as the latter group fell below those of the superior group. The height and weight for the medium group was practically the same as the figures of the Boas-Burk tables of height and weight for American children. The heights and weights for the children of the superior grade followed closely the average figures for more than 30,000 children in private schools in New York City and Chicago, tabulated by Professor Baldwin. The conclusions are that, in this average industrial district, a third approximate closely the average of children whose parents can afford to pay tuition rates; a second third represents the average of American children, and the remaining third is seriously underdeveloped, being in many cases several years under the measurements proper to their ages under a reasonable standard of living. It has been shown that under conditions of abundant nutrition, exercise, air and sleep, stunted children in summer camps in the majority of cases improve rapidly up to the required average. The answer is that better parental incomes are necessary to prevent this undernutrition and substandard development.

Parenteral Injection of Milk

At a recent meeting of the Swedish Medical Association, G. Uddgren reported parenteral injection of human milk in about fifty cases of eye disease. Müller and Thanner reported fine results in their twenty eye cases a year ago, including four with parenchymatous keratitis. They even compared the results of this paraspecific treatment to the benefit from iridectomy in acute glaucoma, and Kühne insists it is one's duty to apply it, but Uddgren is not so enthusiastic. She declares that unquestionably there is something in this paraspecific therapy; applied with due caution it may give gratifying results. The benefit seems to be due to the focal reaction. In her work with it, the milk was derived from healthy wetnurses, and was boiled for five or ten minutes. The injection was repeated two months later, giving first a small preliminary injection, according to Besredka's technic. On account of the danger of milk embolus, the injection must be made very cautiously not to injure a blood vessel and thus let the milk get into the vein. In a few cases she used goat milk, and the results seemed equally good. The temperature rises a little in fifteen or twenty minutes but subsides in half an hour. At the end of the third, fifth and sixth hour it usually runs up again, reaching the maximum between the eighth and eleventh hour and then dropping as in crisis—all within the first twenty-four hours. There may or may not be pains; in some cases they resembled those of influenza. The pulse kept regular throughout, and the leukocytosis induced was not proportional to the temperature. It might be the same in the same person whether 0.5 or 2 c.c. of blood had been injected. As a rule, Uddgren applied this treatment only after failure of other measures. Most of the patients gave a positive Wassermann reaction. A. Steiger is said to have reported in the *Deutsche medizinische Wochenschrift* of recent date that parenteral injection of 10 c.c. of milk did not display the slightest efficacy in his experience with anthrax, furuncles and enlarged lymph glands.

Medicolegal

Providing for Treatment at Special Institutions of Tuberculous Paupers

(Inhabitants of Machias v. Inhabitants of East Machias (Me.), 102 Atl. R. 181)

The Supreme Judicial Court of Maine holds that the plaintiffs were entitled to recover payment for pauper supplies furnished a minor son of a family alleged to have a settlement in the defendant town, where the items consisted of "board, services and medical attendance" at Bangor Anti-Tuberculosis Camp, at Eastern Maine General Hospital, and at the Fairfield Sanitarium for Tuberculosis, a total expenditure of $476.11, covering a period of ninety-two weeks, or practically $5 per week. The court says that it was contended that as a matter of law these charges could not be recovered as pauper supplies; but the court finds itself unable to accede to that view. The statute provides that "overseers shall relieve persons destitute, found in their towns and having no settlement therein," and the expenses so incurred may be recovered of the town chargeable with the support of the pauper. The statute does not prescribe the manner in which, or the extent to which, the relief shall be administered. That must depend on the facts and conditions connected with each call for assistance. The governing rule is that the relief shall be reasonable and proper. It must be suited to the particular needs of the destitute person, whether they be food or clothing or shelter or medical or surgical assistance, or all together. So, too, the situation of the sick admits of such infinite variety that no arbitrary rule for their treatment can be laid down. While the right of reimbursement is purely statutory, being conferred by positive provisions of law, and is not based on any equitable considerations, yet it is the right and duty of the court to view the nature and extent of the relief in the light of present day conditions.

Nursing and medical services have always been deemed included in pauper supplies. The necessity of such services in the case at bar was admitted. Had they been rendered at the patient's home, perhaps no complaint would have arisen. The fact that they were rendered at an institution within the state specially equipped for the treatment of tuberculosis should not of itself place such services outside the pale of the statute. Such beneficial institutions were unknown a generation ago, but their worth is now universally conceded. The test in all cases must be the reasonableness and propriety of the relief provided, and it must certainly be admitted that nowhere can this particular disease, infectious in its nature, be more properly treated than in institutions such as these. Not only can relief be afforded, and the danger of infection avoided, but the patient may be restored to permanent health and a life saved to the community.

The expense incurred here, an average of $5 per week, including board, nursing and medical attendance, was not extravagant, and the misfortune of a father's pauperism ought not to deprive a sick child, in these enlightened days, of the reasonable means of treatment and care. Any other doctrine affronts the dictates of humanity. It was admitted that the overseers of the plaintiff town acted on the advice of a physician after his examination and treatment of the afflicted patient and on the recommendation of a visiting nurse. They evidently met the problem as they found it, and solved it with sound discretion.

Then it was contended that as the pauper was suffering from tuberculosis, which is declared by the Revised Statutes of 1916, Chapter 19, Section 9, an infectious and communicable disease, this case should have fallen under the control of the local board of health, which under Section 69 of that chapter might place the patient in quarantine and charge to the town all supplies for food and medicines. But that contention was without force. Chapter 19 relates to the public health and the prevention of contagious diseases. It affects the affluent as well as the destitute. It had no application in this case.

Itemization Required of Physicians' Accounts

(Willet Bros. v. Western Naval Stores Co. (Tex.), 198 S. W. R. 352)

The Court of Civil Appeals of Texas reverses a judgment of dismissal, and remands for a new trial this case, wherein it was held that the accounts for medical services and medicines set out in the plaintiffs' petition were not sufficiently itemized, judgment being rendered on the pleadings, without testimony. One paragraph of the petition stated that at the special instance and request of the defendant, by and through its certain named agent, manager of its Camp No. 1, in Newton County, Texas, the plaintiffs did render medical service for and sell to the defendant medicine for Camp No. 1, as follows: "July 22, 1912. For Arthur Johnson, examination and medicine, $1.50." . . . "Oct. 12, 1912. For Auther Sapp, 1 visit and medicine, 8.75." The only just criticism that could be made of this paragraph, the court says, was the failure of the pleadings to state the amount charged for examination and the amount charged for medicine to the various parties, or the amount charged for the visit and the charge for medicine. These should have been separately charged, and, subject only to this criticism, this would be a proper averment.

Another paragraph, beginning similarly, but for Camp No. 2, contained, among other items, these: "June 28, 1912. For G. Green, examination, prescription, medicine, $10.15." "June 28, 1912. For Homer Ree, 5 visits, circumcision, medicine, 22.30." The court says that the items in this paragraph were subject to the criticism made on the preceding paragraph. In other words, the charge should be made for the visit, for the examination, for the prescription, and medicine, and the item of June 28, 1912, should have stated so much for circumcision, and so much for medicine. Except for this alleged vice, this paragraph would not be open to objection. In other words, the court means to say that it is not necessary to itemize the medicine, or the kind of medicine, but only the amount charged for the medicine, the amount charged for the examination, and the amount charged for the visit, and the amount charged for the prescription, and for the circumcision. No further itemization of the account would have been necessary or called for.

Likewise, the alleged vice in still another paragraph was that a charge should have been specified, stating what was made for the examination, and what was made for the medicine, and what charge was made for visits. In no further particular was it necessary for the items to be set out in the plaintiffs' pleadings. So far as pretending to itemize the services rendered, except that it was medical service, and the nature thereof, except that a visit was had, or circumcision had, no further particularity was needed with reference to the medicines and services, except the charges that were made therefor.

The court does not believe that the grouping of the facts, in the item, that the persons named were visited and medicine given, should be considered, save when so much was charged for medicine, and so much for a visit. But as the time had been given at which the charges were made, and as the plaintiff evidently knew how much he charged for a visit, he therefore was able, by a mathematical demonstration, to show how much was for a visit, and therefore how much remained in the charge for medicine. In the opinion of this court, therefore, there will be and can be no definite reason why the plaintiff cannot, even in the absence of any written memoranda, be able to state how much he charged for a visit, and how much for examination, and therefore how much he charged for medicine, at the various dates mentioned in the various accounts.

In the form as presented to this court, the exception was a general exception. It was error on the part of the lower court, some of the items being correctly pleaded, to dismiss the entire account and refuse to hear testimony with reference to the justice of it. This court believes that, on another trial of the cause, no trouble will be experienced with reference to the proper pleading, and that therefore the parties may be able, without real trouble, either before the court or before a jury, to have justice meted out to them in this cause.

13. Starch Digestion in Infancy and Childhood.—With a view of gathering data on the questions of starch intolerance and making observations on the capacity of young children to handle various forms of starch, Fleischner and Meyers made some food and feeding studies. Six children were selected about 4 years of age, on whom daily stool examinations were made for a period of about two weeks. They were all apparently normal children and their digestive capacity was likewise what might be expected in an average child. No directions were given as to the diets that the children should receive. They were kept on the usual food given to the children of their age. At the end of this time they were given potato twice daily to determine their tolerance for this type of starch. It was noted that the children were being fed a number of calories far in excess of their requirements for age and weight. However, they were apparently taking care of it and the percentage of carbohydrate was not excessively high. When the potatoes were started twice daily, the other starches were diminished and it is striking that their total carbohydrate intake was definitely less in spite of which they excreted much more starch in their stools. Several facts are emphasized by Fleischner and Meyers: (1) Incapacity to properly handle starches and celluloses is a very common disturbance of the digestive tract of young children. (2) A correct diagnosis can only be made by eliciting a careful history, ruling out other organic diseases by careful physical examination and finally by painstaking stool analyses. (3) The treatment of this condition is essentially confined to an adjustment of diet and institution of proper hygiene. (4) It is high time that pediatrists who have devoted so much attention to a careful supervision of the diet of the first years of life should realize that it is quite as important to carefully regulate the diet between the first and sixth years of life, not only qualitatively, but quantitatively, as the most potent prophylactic means of eradicating a very common form of malnutrition of childhood.

19. Serum Conserved Dressing for Industrial Wounds.—Williams has found that lacerated wounds heal more rapidly and with less trouble when treated as follows: When the wound is first seen the surrounding uninjured skin is cleaned with gasolene, and painted with tincture iodin full strength. No iodin is allowed to come in contact with the wounded surface. Wax is immediately applied. These wounds are dressed daily for the first few days, especially if there is much tissue destruction, but at these redressings the wound proper is not touched, consequently the so-called cleansing of its surface is omitted. An electric blower is applied as a drier, which has the advantage also of preventing the skin from becoming too blanched or parboiled. Burns will heal as rapidly under adhesive as under wax, but it is less easily applied and more expensive. Williams calls this procedure the serum retaining dressing. He says that the serum retained dressing is a rapid healer. Redressings are painless, hence without trauma. This is again conducive to rapid repair. In wounds treated as above outlined, excessive granulations are never seen. Sluggish wounds are also absent.

31. Nitrogen Metabolism and Acidosis After Transplantation of Ureter.—This work was undertaken by Goto to study the metabolism in the dog after a ureter intestinal transplantation. Four dogs were originally operated on. Two showed kidney infection; the other two were not infected, and in these the metabolism was studied; one of the latter showed a marked hydronephrosis and hydro-ureter. The operative results were as follows: Both after the transplantation of the right ureter into the intestine and the ligation of the right ureter, there is generally a moderately increased output of nitrogen in the urine and, in the former instance especially, a retention of nitrogen in the blood, but no change in carbon dioxid content in the blood, probably an evidence of increased tissue catabolism. After removal of the left kidney subsequent to transplantation of the right ureter into the duodenum, renal insufficiency and resulting retention developed. The nonprotein and urea nitrogen in the blood steadily increased and the carbon dioxid content of the blood diminished to the level characteristic of a moderate acidosis. No ketones were found in the blood. The dogs died five to ten days after the nephrectomy under conditions characteristic of suspended renal activity—deep respiration, unconsciousness and sopor.

33. Antiseptic Properties of Organic Compounds.—A study of the inhibitive effect of anilin and some of its derivatives and of the triphenylmethane dyes on certain bacteria leads Kligler to conclude that the germicidal action of the compounds is a function of the benzene nucleus, the added elements or radicals, their number, and in the case of the dyes, probably the quinoid structure of the nucleus. So far as tested, the increase in the number of alkyl radicals increases the antiseptic power. Methyl green is an interesting exception to this rule, for the change of one of the nitrogens to the quaternary salt is accompanied by an almost complete loss in inhibitive action. The antiseptic power is enhanced to a greater extent by an ethyl than a methyl group, and the second alkyl produces a proportionately greater increase than the first. It appears [illegible] the relative position of the introduced group may [illegible]tor in [illegible] the relative improvement in the effectiveness of the compound. The introduction of a methyl group in the nucleus consistently enhances the inhibitive action of the compound and its alkyl derivatives. This is evident from a comparison of the action of anilin and its derivatives with that of toluidin and its corresponding derivatives. The simple anilin derivatives, as well as the dyes, are more toxic for the gram-positive than the gram-negative bacteria. Of the former, *B. subtilis* is more sensitive to the dyes than *S. aureus*, while the reverse is true in the case of the anilin compounds. The most marked selective effect is manifested by the triphenylmethane dyes. *B. aerogenes* and *B. typhosus* possess a higher resistance to these substances than *B. coli* or *B. dysenteriae*. The last is exceedingly sensitive. This partial specificity is apparently a function of the molecule as a whole.

34. **Elimination of Iron and Distribution in Liver in Experimental Anemia.**—In the continuous blood destruction, essentially a chronic experimental anemia, caused by infecting the dog with *Trypanosoma equiperdum*, no increased elimination of iron was observed in the feces by Dubin and Pearce. The storage of iron in the liver and spleen under these experimental conditions is somewhat greater in amount, but of the same general character as in transient experimental anemia. Splenectomy before or after infection, that is, the development of anemia, influences neither the elimination of iron in the feces nor its storage in the liver. The retardation of the course of the trypanosome infection and thus the production of a more chronic anemia by treatment with a trypanocide, arsenobenzol, likewise does not affect iron storage. These experiments therefore have failed to reproduce the changes in iron metabolism seen in certain of the chronic hemolytic anemias of man.

35. **Blood Pressure in Auricular Fibrillation.**—The technic of Gaertner is shown by Cohn and Lundsgaard to be especially applicable to the study of the blood pressure in fibrillation of the auricles. The use of this technic has brought out a defect in the so-called fractional method of taking the pressure in this condition; the brachial and digital curves cross. Taking pressure of both brachial and digital arteries has shown that certain different types exist; first, that in which both central and peripheral pressures are stable; second, that in which the more central pressure is stable and the peripheral pressure fluctuates; and third, that in which both pressures fluctuate together.

36. **Peripheral Blood Pressure.**—Experiments on dogs showed that whereas the pulse pressure in the larger arteries (femoral) varies extensively, it varies within narrow limits only in the small ones (dorsal artery of the foot). These results supply an experimental explanation for the fact that in man uniform pressure readings were obtained by Gaertner's method at the digital artery. The experiments show likewise that in certain instances the level of pressure is maintained when fibrillation of the auricles sets in. It is therefore clear that when the mechanism of the heart beat in man changes to fibrillation of the auricles, a change, that is a fall, in pressure need not necessarily develop.

38. **Mercuric Chlorid Intoxications.**—In the acute mercuric chlorid intoxications which have been induced in dogs by MacNider death has been due either to the shock associated with the severe mercury enteritis or to a delayed kidney injury. The injury to the kidney has been constantly associated with the development of an acid intoxication. The delayed kidney injury is not due to the action of the mercury as such during its elimination by this organ. The manner in which mercuric chlorid induces an acid intoxication is under investigation.

40 *Elective Localization of Streptococci from Epidemic Poliomyelitis. E. C. Rosenow, E. B. Towne and C. L. v. Hess, Rochester, Minn.—p. 313.

41 *Agglutination of Pleomorphic Streptococcus Isolated from Epidemic Poliomyelitis by Immune Serum. E. C. Rosenow and H. Gray, Rochester, Minn.—p. 345.

42 *Treatment of Fifty-Eight Cases of Epidemic Poliomyelitis with Immune Horse Serum. E. C. Rosenow, Rochester, Minn.—p. 379.

39. **Etiology of Epidemic Poliomyelitis.**—A pleomorphic coccus has been isolated from and demonstrated in affected tissues in all the cases examined of poliomyelitis that occurred in different epidemics and in widely separated parts of the country. Pure cultures of this organism have been isolated many times and it has been demonstrated in films and sections of brain and cord many months after they were placed in 50 per cent. glycerol. The authors hold that in view of these results the presence of this organism in the diseased tissues cannot be considered an accidental contamination. On injections of cultures into young rabbits and guinea-pigs it localizes specifically in the nervous system and produces flaccid paralysis and changes in brain and cord which resemble those in poliomyelitis in man. From the brain and cord of these animals the organism can be isolated and the disease again produced. The organism has been rendered filtrable. By means of the same methods the identical organism has been isolated constantly from the brain and cord of monkeys paralyzed with fresh, glycerolated and filtered virus. The serums of persons and of monkeys, having recovered from poliomyelitis, agglutinate specifically the more sensitive strains both from human and monkey poliomyelitis. Injections of the recently isolated aerobic cultures into monkeys renders them refractory to virus. The aerobic form of the organism from human and monkey poliomyelitis produces antibodies in the serum of horses, in a large amount common for both, cross-agglutinating these strains specifically in high dilution. The serum of a horse immunized with freshly isolated strains from monkeys protected monkeys relatively against intracerebral inoculation of virus and had pronounced curative effects in the treatment of human poliomyelitis. Early intravenous injections were followed by almost immediate cessation of symptoms in a large series of cases.

40. **Localization of Streptococci from Poliomyelitis.**—A thorough bacteriologic study of twenty-two cases, has shown that the streptococcus found so constantly in poliomyelitis tends to localize electively in the central nervous system in young guinea-pigs, rabbits, puppies and kittens, and less often in adult animals of these species and in adult monkeys. The symptoms and lesions produced resemble those found in poliomyelitis in man. Cultivation on artificial media, especially under aerobic conditions, usually destroys promptly the elective localizing power, as does successive animal passage. The results obtained indicate strongly that the streptococcus under consideration is not merely a secondary invader, but that it has etiologic significance in poliomyelitis.

41. **Agglutination of Cocci from Poliomyelitis.**—The results of this study further support the view that the elective localizing power of the pleomorphic streptococcus as first demonstrated by Rosenow, Towne and Wheeler, has significance and that it in some way bears etiologic relationship to epidemic poliomyelitis.

42. **Treatment of Poliomyelitis with Immune Horse Serum.**—Rosenow reports in detail the results obtained from the serum treatment of fifty-eight cases of poliomyelitis which occurred in Davenport, Iowa, and the surrounding locality during the latter part of the summer and in the autumn of 1917. Intravenous injections were made to the exclusion of intraspinal injections for the following reasons: 1. The best results were obtained by this method in the protection of monkeys against virus. The serum was activated for the same reason. 2. Invasion of the nervous system in poliomyelitis is only a part of a more or less generalized systemic infection (Flexner and his co-workers). This was particularly true in this epidemic. Infection of the tonsils, the cervical and mesenteric lymph glands and the gastro-intestinal tract was often marked. 3. The spinal fluid in poliomyelitis is known not to contain the virus. The disease process is situated chiefly in the depths of the cord which can best be reached through the circulation, particularly if lymph drainage toward the spinal canal is promoted by the

withdrawal of spinal fluid. 4. Intraspinal injections of immune serum, human and horse, are known to be irritating and at times dangerous.

- Altogether, 94 intravenous injections were made. In no instance was there a primary toxic action noticeable, and in only six (10 per cent.) was there later evidence of serum disease. If the temperature was normal no rise occurred, if above normal, an immediate drop without an initial rise was the rule, especially early in the disease. The low incidence of serum disease in this series, 10 per cent., as compared with the incidence of 33 per cent. in Nuzum and Willy's series, and apparently a more immediate beneficial effect, Rosenow suggests, may be due (aside from an apparently more powerful serum, the agglutinating power being much higher, smaller doses being necessary to be effective) to the fact that intravenous injections only were given. Altogether fifty-eight patients with poliomyelitis, irrespective of the severity or type of the disease, were treated. Of these, ten died, a total mortality rate of 17 per cent. Excluding seven of the fatal cases in which the patients were practically moribund at the time of the serum treatment, there were three deaths, a mortality of 6 per cent., in fifty-one cases in which the serum had a fair chance. This is in marked contrast to the twenty-three untreated patients, of whom nine died, a mortality of 35 per cent. Including the moribund patients as untreated, there were sixteen deaths in thirty, or a mortality of 53 per cent. Paralysis did not develop in a single instance when treatment was begun before its onset, and all recovered. No extension occurred following the giving of serum in the patients who recovered and in whom paralysis was marked at the time of the serum treatment. In only three or possibly four patients, or 8 per cent., receiving the serum will there be permanent impairment of function, and in all but one this will be slight.

48 Three Unusual Cases of Parasitism (Slug, Myriapod and Cockroaches) Reported in Man. C. W. Stiles.—p. 138.

47. **Natural Occurrence of Eosinophilias.**—When the juices obtained from *Hypoderma* larvae, either diluted or otherwise, are injected under the skin of a susceptible animal, the first effect noticed will be local. At the point of injection a blisterlike spot will be seen, and a necrotic area will occur. In twenty minutes to half an hour, swelling will be noted. The necrotic spot in the center will be depressed. Smears made from the swelling some hours later reveal the presence of an *eosinophilia*, and if the material which was injected contained bacteria, phagocytosis by the eosinophils. This observation of phagocytosis by the eosinophils was made by Hadwen and certified by Dr. B. H. Ransom at Washington, D. C. The reason for the eosinophils assuming the rôle which is usually assigned to the neutrophils, is apparently because the bacteria are rendered attractive by their being bathed in the verminous juices. It is a well-known fact that, as a rule, in verminous anemias the percentage of eosinophils is high, but in some instances they may be very scarce. Weinberg and Séguin noted this in their experiments and suggest that the few eosinophils which were in the circulation had been attracted to the parts affected in order to repel a verminous invasion. Experiments are contemplated to determine what curative effects the injection of worm juices may have on such cases.

52 *Comparative Absorbability of Local Anesthetics from Urethra. T. Sollmann, Cleveland.—p. 159.

49. **Digitalis in Auricular Fibrillation.**—Two different types of effects were seen by Cushny in the mammalian heart under the action of the digitalis series. *A*. In the normal heart digitalis causes slowing through stimulation of the inhibitory center in the medulla, and if this is eliminated, the dominant feature is an increase in the excitability which leads to the inception of independent rhythm in the auricle and ventricle, and later to discharge from different points of the same chamber, which culminate in fibrillation. *B*. In the excised mammalian heart exhausted by prolonged perfusion with Ringer's solution, digitalis causes slowing and block which closely simulates that induced by inhibition in the normal heart, but which is not prevented by atropin and therefore arises from direct action on the heart. The pacemaker emits fewer impulses and these are still further reduced owing to impaired conduction to the auricle from the Keith-Flack node and to the ventricle from the auricle. The auriculoventricular block becomes further developed, the ventricular beats become slower and finally the chamber ceases in more or less complete systole without fibrillation. In auricular fibrillation in man, digitalis slows the pulse and this is independent of the inhibitory mechanism, for it is not prevented by atropin. In the mammalian heart in situ when auricular fibrillation is induced, strophanthin finally arrests the irregularity of the ventricle, by impairing conduction, but the pulse is not slowed owing to the accelerated idioventricular rhythm induced by the drug. In auricular fibrillation induced in the perfused heart, strophanthin renders the ventricle regular through impaired auriculoventricular conduction and at the same time slows its rate. The Type A, inhibitory slowing, occurs in man and animals with normal cardiac rhythm. The Type B, slowing through direct cardiac action, occurs in most cases of auricular fibrillation in man, in rare cases of normal rhythm in man, in the perfused mammalian heart, whether the normal rhythm is preserved or the auricle is fibrillating, and in the frog. The primary cause of the Type B in man and animals is the malnutrition of the heart; the auricular fibrillation merely favors its appearance by accentuating the fundamental cardiac malnutrition.

50. **Action of Tartrates, Citrates and Oxalates.**—The different behavior of tartrate, citrate and oxalate as regards tolerance and cumulation is held by Salant and Swanson to be unfavorable to the theory which assumes that the physiologic effects of their acids, and soluble salts, are due to calcium precipitation or to the transformation of ionic calcium into nonionized calcium in the cell.

51. **Poisonous Action of "Asetake."**—The experiments and observations made by Muto show that the poisonous action of "Asetake" (sweat fungus) agrees exactly with that of muscarin.

52. **Absorbability of Anesthetics from Urethra.**—The experiments reported on by Sollmann were made on male dogs, anesthetized with morphin and ether. The urinary bladder was exposed through a suprapubic incision. An opening was made near the neck of the bladder. Through this an elbow cannula of small lumen and thick walls was introduced into the posterior urethra, and tied in position. The exterior end of the cannula was connected with a small stop-cock, through which the injections were made. Another elbow cannula was tied into the urethral meatus and used for the collection of the urethral fluid. The anesthetics were used in the form of the hydrochlorids. Different animals vary rather widely in their absorbing power. To permit their comparison, an average of absorption was established for each series of observations, by averaging the percentage of absorption of the six drugs used. The relative absorbability of each drug is as a percentage of this "average of absorption." The absorbability of the hydrochlorids of the local anesthetics from the dog's urethra is in the ratio of: apothesin and beta-eucain = 86.6;

novocain = 97.6; cocain = 100; tropacocain = 105.0; alypin = 111.3. The rate of absorption increases with the dose and concentration; not only absolutely but also per cent. For instance, increasing the dose and concentration three and one-third times increases the absorption four and one-fourth times. The absorption is most rapid in the first ten minutes, but continues quite markedly even after this time. The absorption is not materially hastened by rendering the anesthetics alkaline.

6 *Infected Wounds of Knee Joint. K. W. Monsarrat.—p. 311.
7 Prevention of Spread of Epidemic Disease at Schools. H. M. Fletcher.—p. 313.

6. **Infected Wounds of Knee Joint.**—Thirty-eight cases are reviewed by Monsarrat. Of 25 patients treated within four days of the receipt of the wound, 18 recovered without amputation; 4 recovered after amputation and 3 died. This shows a recovery of 72 per cent. without amputation. Of the 13 admitted on the fifth day or later, 4 recovered without amputation; 3 recovered after amputation and 6 died. This shows a recovery of 30 per cent. without amputation. Another point of importance showing the influence of early treatment is the recovery of function in the joint. Of the 22 patients surviving without amputation, 13 left the hospital with recovery of function in the joint—that is to say, with a greater or less range of voluntary movement. Of these 13 patients, 3 were admitted the day following the wound; 4 were admitted on the second day following the wound; 5 were admitted on the third day following the wound and 1 was admitted on the seventh day following the wound. It was in by no means always the least complicated case that there was a good functional recovery. These groups of figures indicate the urgency of operative treatment in infected knee joint wounds, and the fair results which may be expected in cases so treated.

Punctured, penetrating wounds of the joint with effusion are not included in this paper. All that is required in such cases is fixation. This should be both absolute and prolonged. In early infections—that is to say, in cases in which the infection is not so established as to have disorganized the joint—the details of the operative treatment endorsed by Monsarrat are as follows: (*a*) excision of the wound, or wounds, including the capsular and synovial membrane wounds; (*b*) evacuation of effusion; (*c*) removal of foreign bodies and of detached bone fragments; (*d*) transverse incision into the joint a fingerbreadth above the patella 4 inches in length; (*e*) either (and usually) no sutures or catgut suture of the excised wounds passing through synovial membrane only. No drainage material passed into the joint; (*f*) fixation on splint, with fixed extension and elevation of the limb to an angle of 45 degrees at the hip joint. It is usually necessary to maintain the patency of the transverse incision into the joint by passing a pair of dressing forceps at the daily dressing for three or four days. The results shown in the cases of which details are given here appear to demonstrate the value of this method of operative treatment in cases in which infection is not advanced. When the joint wound is complicated by fracture the question of a primary resection of the joint may be entertained if the stability of the joint is otherwise doubtful. When cases submitted to arthrotomy continue to exhibit signs of active infection on the days following operation a secondary amputation should be done; no lesser procedure is likely to be successful. Delay in amputating in such cases beyond the third day after arthrotomy is likely to be dangerous.

Amputation is advisable if infection of the joint is complicated by a serious bone injury. Amputation is further indicated if the joint wound is complicated by injury to the femoral or popliteal artery or by section of internal or external popliteal nerves. In the treatment of patients transferred from other units and admitted in the subacute stage, in which the joint is more or less infiltrated with septic granulation tissue and there are various operation wounds more or less providing drainage in Monsarrat's opinion the choice of procedure lies between: (*a*) leaving them alone carefully splinted and only operating if some secondary collection in the thigh or leg presents itself; (*b*) amputation. This should be chosen when signs of general infection and septic intoxication persist; when secondary collections or tracks are present in the popliteal space; when it is obvious from the extent of the bone destruction that a weight-carrying limb cannot be anticipated. A large proportion of the cases with posterior collections and tracks end in secondary hemorrhage. Bone loss, which will leave crippling, deformity and joint disorganization, which has resulted in falling back of the tibia from the femoral condyles, will always lead to a decision to amputate.

14. **War Psychoneurosis.**—While admitting that from commotion or prolonged stress of war, a stable nervous organization may develop an acquired emotivity, Mott says, that it seems that the psychogenic or autosuggestive factor, acting on a prewar emotive brain is the chief determining cause of war psychoneurosis, and the neurotic patient's protest of anxiety lest he be boarded out of the service, or not allowed to go to the front, is really in many cases an indication of an exhausting conflict which has been going on continually in his mind between the self-conservative instinct and the moral obligation of duty and patriotism, which has its roots in the social herd instinct.

15. **Effects of Leukocytes on Wounds.**—Attention is drawn by Wright to an all important principle. When the surgeon seeks information from the bacteriologist as to whether the wound is making progress in sterilization, and whether secondary suture may or may not be undertaken, the bacteriologist is wont to take the pus and plant it out in such a manner as to secure the survival of the microbes and the destruction of the leukocytes. In other words, the bacteriologist is wont to

make what Wright calls a "necropyoculture." And then the surgeon, when he undertakes the secondary suture, very often obtains a result much more favorable than the findings of the bacteriologist would appear to warrant. If he wants to be a help to the surgeon, the bacteriologist should change his procedure. Instead of making films and neuropyocultures, and reporting the number of microbes seen or rescued alive from the pus, he should make biopyocultures, that is, provide in his cultures conditions favorable to phagocytosis, and should then report whether the leukocytes on the wound surface—assuming that the surgeon gives them a fair chance by effacing dead spaces and surface desiccation—are competent to get the better of the remaining bacterial infection.

23 *Six Cases of Paroxysmal Tachycardia. W. E. Hume.—p. 131.
24 Abscess of Brain. W. B. Warrington.—p. 141.

20. **Injury to Chest.**—The following are some of the main points brought out by Dean's experience with these cases: If a hemothorax has been produced by a bullet wound it is very improbable that sepsis will occur. Of those produced by shell wounds about half are infected. Many patients with penetrating wounds, both bullet and shell, when seen at the end of a week, show no signs of lung injury. Pain and, more important, tenderness and hyperesthesia of the skin in a case of hemothorax should make one strongly suspect that there is infection. Cyanosis and dyspnea generally mean that there is infection of a hemothorax unless the latter is a very large one, but of all the early symptoms of infection, sleeplessness is perhaps the most valuable. The loss of weight occasioned by a septic hemothorax is a striking feature and in excess of and more rapid than that produced by sepsis in other situations. Lobar pneumonia complicating a hemothorax is not as serious as might have been expected. Contrary to expectation, abscess of the lung is a rarity. Bronchial breathing is often heard over a hemothorax. The most valuable signs for the differential diagnosis between a hemothorax and pneumonia are the degree of impairment of the percussion note and the presence or absence of râles. The roentgen rays are essential for the diagnosis and treatment of hemothorax.

After shock has subsided, pallor is not seen in patients suffering from even a large hemothorax, if it is sterile. A hemothorax, if of moderate size, should be aspirated after six or seven days, and no harm will result if this is done as a routine for every hemothorax. Clotting to a degree sufficient to prevent efficient aspiration of a hemothorax is rare. Secondary hemorrhages after the first few days do not occur in sterile cases. The position of the diaphragm is often abnormally high in cases of hemothorax, and this fact is to be remembered when aspiration or resection is performed. It is rare for organisms to be found by culture in a hemothorax fluid if they cannot be seen in a stained film prepared from the fluid. Resection is not indicated for every case of infected hemothorax. The bacteriology, general condition of the patient and the size of the hemothorax must all be taken into account in coming to a conclusion as to whether resection or aspiration should be done. The advantages of preliminary aspiration when it is certain that resection will be necessary are overbalanced by the loss of valuable time entailed by this procedure. When a hemothorax is infected solely by pneumococci, a better result will probly be obtained by aspiration than by resection.

The Carrel-Dakin method applied to the treatment of septic hemothorax after resection will prove to be of the very highest importance and value, since by its means secondary infection, which is one of the chief dangers of this class of case, can be almost completely eliminated. For resection a light chloroform anesthesia is generally safer than, and preferable to, a local one. Cases in which there is a gaping wound into the pleural cavity carry a very bad prognosis. The virulence of the infection rather than the time before drainage is established determines the density of the walls of the empyema cavity and the amount of collapse of the lung in cases of septic hemothorax. It is of great importance to get patients for whom resection has been done out of bed for a few hours at the earliest possible date, when the general condition and the pulse rate allows. The displacement of the mediastinum may take considerable time to right itself, even after operation, so that care must be taken not to mistake the abnormal position of the apex beat as evidence of a dilated heart. Bronchial breathing, râles, and an impaired resonance at the left base may be the only signs of even a large pericardial effusion. The rarity of subdiaphragmatic abscess is somewhat surprising. By far the commonest cause of death in cases of chest wound which reach the base is sepsis occurring in a hemothorax. A lower mortality in infected cases is to be gained by earlier diagnosis and more efficient treatment of sepsis, rather than by early prophylactic operations undertaken as a routine.

21. **Sulphemoglobinemia.**—A case of sulphemoglobinemia is described by Long and Spriggs showing the usual features of cyanosis—constipation, debility, and headaches. The band of sulphemoglobin was demonstrated in the blood and could be seen through the lobe of the ear. The patient complained of much abdominal pain, for which two operations had been performed without any sufficient cause for the pain having been found. There was a large element of neurosis. Improvement followed a diet consisting mainly of carbohydrate foods, the use of purges and antiseptic medicines, and the removal of carious teeth; but the patient is still the subject of the complaint. Attempts to confirm the findings, described in some other cases, of a nitrite producing bacillus in the saliva and of a substance in the blood serum which strongly reduces oxyhemoglobin solutions were unsuccessful in this patient.

22. See The Journal, April 6, 1918, p. 998.

23. **Cases of Paroxysmal Tachycardia.**—Six cases of paroxysmal tachycardia in soldiers in France are described by Hume. Three of the patients had suffered from attacks of paroxysmal tachycardia before enlistment. In no case was there any evidence of valvular disease of the heart, nor could any infection be traced as the cause of any pathologic change in the heart except in one case; in this case diphtheria had undoubtedly caused a pathologic change in the heart muscle which brought about the liability to attacks of paroxysmal tachycardia. In four of the cases attacks could be readily induced by comparatively slight exertion, and it is noteworthy how little general embarrassment the attacks caused. In view of the fact that there was no gross valvular or muscular disease of the heart, it appeared possible to Hume that the attacks might easily be induced by stimulation or depression of the controlling nerves of the heart. Prompted by this consideration, the inhibitory action of the vagus was removed by the injection of atropin sulphate and the sympathetic nerve was stimulated by the injection of epinephrin chlorid. In no case did these methods of altering the nervous control of the heart bring about a paroxysmal attack. On each occasion the response was such as is known to occur normally. Nor did alterations in pressure or in the volume of the peripheral circulatory system produce attacks: thus the response to inhalations of amyl nitrite was perfectly normal.

Endeavors were made to increase the venous filling of the right side of the heart by pressure on the abdomen and alterations in posture. On one occasion in one case a momentary stoppage of the paroxysm seemed to be caused by firm pressure on the abdomen. Two of the patients had discovered that flexion of the thighs on the abdomen with the head downward, together with a squeezing of the abdomen by the thighs, would on occasions bring a proxysm to an end. Inhalations of oxygen and carbon dioxid merely caused slight alterations in pulse rate. The six venous pulses have very similar characteristics; in each there are either one or two waves which fall within the period of ventricular systole, and in none can a separate A wave, evidence of auricular contraction, be detected. A consideration of the venous pulses and the electrocardiographic records suggests that these were cases of tachycardia of ventricular origin. This theory is supported by the appearance of frequent extrasystole in one case during the nonparoxysmal periods.

Bulletin de l'Académie de Médecine, Paris

March 5, 1918, 79, No. 9

25 *Coxa Vara and Obesity. E. Kirmisson.—p. 183.
26 *Lost Tendon Reflexes with Skull Wounds. Souques.—p. 194.
27 *Buried Drainage for Elephantiasis. C. Walther.—p. 195.
28 *Chemical Tests of Drinking Water. L. C. Maillard.—p. 198.
29 *Work of Army Medical Department. Sieur.—p. 201.

25. **Coxa Vara and Obesity.**—Kirmisson has been impressed by the frequent development of coxa vara in adolescents along with a general tendency to obesity. This occurs too often for it to be merely a coincidence, especially as a familial tendency is also evident. In one family described, three children have had coxa vara since the period of puberty and the mother also had coxa vara as a girl, and all four show pronounced obesity. In another family one girl of 11 had double coxa vara develop and the tendency to obesity is marked. The parents and the five other children are healthy but two are inclined to obesity. Several members of a third family show obesity and in one girl of 12 the upper epiphysis of the femur became separated, which he regards as practically the equivalent for the coxa vara in the other cases. Abortive coxalgia is another tendency in the same line. The obesity seems to be the connecting link between them all, and certain features of it, particularly the puffiness of the face, recall myxedema and suggest a possible thyroid origin. Radioscopy in two of his cases failed to show anything abnormal in the pituitary region.

26. **Loss of Tendon Reflexes After Wounds of the Skull.**—Souques warns that the traumatic meningitis after a war wound of the skull is liable to abolish the tendon reflexes permanently. This must not be mistaken for tabes, etc., later.

27. **Buried Drainage for Elephantiasis.**—Walther reports the outcome in cases of elephantiasis of the leg in which he diverted the edema fluid in the legs into the abdominal cavity by means of a rubber tube tunneling under the skin. A No. 10 or No. 12 nonperforated rubber tube is passed through the deep layer of the fascia superficialis from the incision in the anterior internal aspect of the thigh to the abdominal incision, the ends of the tube fastened with one stitch to one lip of the incision in the aponeurosis. One opening in the side of the upper end of the tube is made to insure the evacuation of the superficial lymphatics. The success surpassed all anticipations in the three cases reported here. In two the elephantiasis of one leg was of four years' standing; in one the cure is complete to date, twenty months since the operation. In the other case the elephantiasis has subsided but the skin has not yet regained its normal aspect.

28. **Chemical Tests of Drinking Water.**—Maillard regards the determination of the chlorids in the water as a reliable test of its purity. When this test was negative, the bacteriologic tests were always negative also, and vice versa. When the chemical test demonstrated that the water was good, the bacteriologic findings never showed that it was frankly bad. He always found the sodium chlorid content between 8 and 17 mg. in the pure waters while 15, 20 or 35 mg. betrayed manifest pollution. It is indispensable to know the average chlorid content of the pure waters in the region. This can be determined in a few hours by analysis of a certain number of the sources of the water. This establishes the normal chlorid content of the basin, so that any variation from this attracts attention at once. In one valley into which the troops came, he rapidly determined that the standard for the pure water in the valley was 15 mg. sodium chlorid; 0.5 mg. oxygen consumed by organic matters; the hydrotimetric degree, 31. Of the eleven springs in the valley, nine showed this standard; one showed 20 mg. sodium chlorid, suggesting contamination, and one showed 12 mg. with hydrotimetric degree of 27, suggesting flushing with inadequately filtered rain water. These springs were not allowed to be used, and the bacteriologic findings showed at least 1,000 colon bacilli in each of these two springs while in the others they ranged from zero to 20, and only in three reached 100.

38 *Autogenous Vaccine in Enterococcus Sepsis. L. Langeron.—p. 43.
39 Severe Nephritis; Consecutive Nephralgia Cured by Decapsulation. H. Dufour.—p. 47.

35. **Laboratory Diagnosis of Spirochete Jaundice.**—Pagniez and his co-workers found in 102 men with infective jaundice that the spirochetes were present in the urine in largest numbers between the fifteenth and the twentieth day, although in the severer cases the urine contained spirochetes during the jaundice phase. They persist long in the urine; some few were found as late as the thirty-fifth and forty-fourth days. The spirochetes are very fragile and disappear from the urine as it ferments. By adding to the urine in the vessel in which it is collected 5 per cent. of a 40 per cent. solution of formaldehyd the urine is prevented from fermenting while the spirochetes are fixed at the same time. By this means the spirochetes are kept intact and show up in urine from eight to twenty-two days old. Centrifugation can be dispensed with by using the ligroin method to collect the spirochetes in the upper part of a test tube. For this, 3 or 5 c.c. of alcohol (95 per cent.) are added to 40 or 50 c.c. of urine (with 5 per cent. formaldehyd as above) in a large test tube (22 by 22). When well mixed, ligroin is poured in to a height of 2 or 3 mm. Plug with a cork and agitate violently for a minute; then set aside, propped upright, for half an hour or more. With a pipet on a rubber tube, take up the supernatant fluid and deposit three drops on a slide. Mix with them 2 drops of alcohol and spread out in a very thin layer; dry in the incubator and treat as usual. The preferable staining technic seems to be with silver preceded with tannin, followed by thorough rinsing, with care not to allow boiling on the slide—the usual Fontana and Tribondeau technic. They never found the spirochete in the blood by direct examination, but in three of seven cases this revealed it in the cerebrospinal fluid. In the sputum of eight patients with the typical jaundice they found swarms of spirochetes, but do not venture to say whether they were the specific spirochetes as no tests of them were made on animals. Besides the spirochete that seemed to be the specific one, Vincent's spirillum was numerous.

36. **Hematemesis After Vaccination Against Typhoid.**—The man of 30 had had vague and transient stomach disturbances at times, and after a severe reaction to injection of a mixed vaccine, he had three successive hemorrhages from the stomach and melena for several days but no pain in the stomach. The case warns that known lesions in the stomach should impose extra caution in the use of antityphoid vaccination.

38. **Serotherapy in Enterococcus Sepsis.**—Langeron reports a case of enterococcus sepsis in a man of 30 in which prompt improvement followed injection of a warmed autogenous vaccine a week after the first symptoms. A fixation abscess first started up to secrete after the injection of the vaccine.

40 Tuberculosis in the Army. Meslier.—p. 31.
41 *Surgery of Peripheral Nerves. A. Hesnard.—p. 33.
42 *Injury of Eyes in the Gassed. M. Teulières.—p. 37.
43 *Bacteriology of Wounds under Hot Air. C. B. Lafaye.—p. 39.
44 Rupture of Both Kidney and Spleen. H. L. Rocher.—p. 41.

41. **Surgery of Peripheral Nerves After War Wounds.**—Hesnard warns that the patient's statements as to the site of the sensations of paresthesias can seldom be relied on to

locate a lesion of a peripheral nerve. Pinching the trunk nerve is more instructive, but the findings cannot be accepted as indicating repair unless known to have been previously negative. He warns further that there should not be the least delay before operating when symptoms indicate compression of the nerve. When causalgia was improved by heat, it has proved to be of reflex origin in his cases. The effect of heat also serves to differentiate certain reflex disturbances from those due to obliteration of an artery.

42. **Eye Lesions in the Gassed.**—Teulières gives an illustrated description of a typical case of severe injury from the gas recently used by the Germans (*sulfure d'éthyle bichloré*). Among 1,500 gassed men in one advanced service, in only twenty-three were the eye lesions severe, including three cases of ulceration of the cornea and one panophthalmia. Some of Teulières' cases have proved very tenacious; one man is still under treatment since last September. The conjunctivitis, photophobia and lacrimation are still intense, and the conjunctiva looks like porcelain, but the corneal lesions are healing and the leukomas are marginal, so that vision is not much impaired.

43. **Hot Air Treatment of Wounds.**—Lafaye receives in his service for hot air treatment torpid wounds which refuse to heal under other measures. The bacteria in the wounds do not seem to be modified by the jet of superheated air that is played on the wounds, but he emphasizes that no anaerobes were found in the wounds examined. The combination found most resistant was the staphylococcus plus the enterococcus. The staphylococcus was found in thirty-eight of the forty most torpid wounds, which suggests that antistaphylococcus serum might be useful for local application in these wounds with tendency to atony.

45 *Primary Suture of War Wounds. G. Gross.—p. 145.
46 *Serotherapy and Lymphotherapy. Dezwarte.—p. 148.
47 Lip Reading. Lagarde.—p. 151.
48 Bacteriologic Control of War Wounds. G. Rosenthal.—p. 153.
49 Treatment of Cardiac Insufficiency. M. Leconte.—p. 155.

45. **Primary Suture of War Wounds.**—Gross describes the technic in minutest detail. He declares that the primary suture of war wounds was placed on a safe basis for the first time by Tissier's announcement that the only contraindication to primary suture is the presence of the streptococcus in the wound. Every war wound free from the streptococcus should be sutured. Cultivation of the germs is the only safe guide. Fulminating putrid infection is always the work of anaerobes plus the streptococcus. It proliferates rapidly only in fluid mediums. At 37 C. its cultures are characteristic in five or six hours. The swabs should be taken from all parts of the wound, between the fourteenth and eighteenth hours, and ordinary bouillon slants of gelose with lactose litmus, and Veillon gelose should be inoculated. Streptococci have been found in only 10 or 15 per cent. of war wounds, and associated with anaerobics only in 6 or 8 per cent. The general mortality at the advanced post No. 12 has dropped from 14 to 10 per cent. since the wounds have been systematically sutured when the streptococcus is not present and the loss of substance is not too great. The suffering is very much less after the suture, and the danger of secondary infections is warded off. By the time the unsutured wounds reach the hospitals in the home zone, fully 80 per cent. contain streptococci. Besides the advantages for the wounded, the primary suture saves time and effort for the hospital force, and is a great economy in the matter of dressings, while the service gains by the men being ready to leave the hospital by the twentieth day. The fractures leave the ambulance with the wound closed and often the fracture is consolidated. The men have to be kept until healing is complete, usually for fifteen days.

He describes the excision of the wounds *en bloc* or *en cône* or exposing the entire path of a seton wound. All blind exploration is repudiated; everything should be open. With lesions of bones, it is only necessary to remove the free sequesters; all operations on the bones should be very economical. No antiseptic should be used except possibly ether and iodoformed ether for bone lesions. Perfect hemostasis and good coaptation of the tissues are indispensable. It is sometimes advantageous to make a deep suture with wire, using three or four stout bronze wires. The skin is sutured with horsehair; a large roll of gauze is applied above, and the ends of the wires are tied over the roll. By this means hemostasis is insured and no dead space is left. The roll is left until the horsehair is removed, if not soiled with oozing. The sutures are not removed until the tenth or twelfth day, war wounds taking longer to heal than the wounds of peace.

46. **Serotherapy and Lymphotherapy.**—For nine years Dezwarte has been studying whether lymph is not better than serum for what we call serotherapy. He argues that the organism presents a defensive reaction on the part of the lymph glands to each and every disease that happens along, almost without exception. From tonsillitis to tuberculosis and cancer, the lymph glands react first and foremost, and it seems only logical to take advantage of the cellular elements involved in the defensive reaction in the lymph glands. Serotherapy should be supplanted by lymphotherapy. A beginning has been made in this line with autoserotherapy and Wright's vaccines. He suggests that repeated lymphatic reactions might prove useful in sensitizing living bacilli, passing them through series of animals and using the animals' lymph for the vaccine. Or the bacilli could be sensitized by mixing with lymph in the test tube. Besredka's technic sensitizes living bacilli with antibodies. Utilizing, instead of this, the lymphatic reaction would be much more like the natural methods of defense on the part of the organism.

53 *War Wounds of Laryngotracheal Region. Guisez.—p. 97.
54 Heliotherapy, Phototherapy and Fresh Air in Tuberculosis and for War Wounds. R. Brunon.—p. 100.

50. **Resection for Fracture of Joint.**—Leriche refers to primary subcapsular periosteal resection when the joint has been entered by a fragment of shell. In a hospital, 12 kilometers back of the front line, resection was done in 48 per cent. of ninety cases of severe war wounds of the knee; arthrotomy in 54 per cent., and in 5 per cent. the limb had to be amputated. The resection was a success in all but one case, and he advocates it as a routine measure which would much reduce the number of amputations otherwise necessary and the number of cases of fatal shock. This view is contrary to the conclusions adopted at the last meeting of the Interallies Surgical Conference which affirmed that primary resection now is only exceptionally indicated, and that, in any event, primary resection for the purpose of obtaining a better functional outcome, should be abandoned. Leriche presents an array of arguments to combat both these assumptions.

52. **Orthostatic Tachycardia.**—Leven insists that a number of orthostatic phenomena which have been ascribed to toxic action are in reality merely reflex manifestations. Those connected with dilatation of the stomach, especially orthostatic tachycardia, can often be cured at one stroke by lifting up the stomach. He reports a typical instance of the instantaneous relief of tachycardia by gastropexy in a soldier of 27. Standing, his pulse had been 120; reclining, or standing with the stomach pushed up into place, the pulse was 60. His attacks of pain in the region of the solar plexus, pallor, temperature of 40 C. and weak pulse of 60 formed the syndrome common with extreme sagging of the dilated stomach. After reducing the size of the stomach by taking folds in the posterior aspect with ten silk sutures, and fastening the stomach to the abdominal wall, the pulse gradually returned to approximately normal figures. Orthostatic tachycardia

should suggest dilatation and ptosis of the stomach, as also orthostatic reduction in the blood pressure, orthostatic pallor and lassitude, orthostatic hyperesthesia of the solar plexus, orthostatic albuminuria and orthostatic dilation of the pupils.

53. **War Wounds of Laryngotracheal Region.**—Guisez reviews the long difficult treatment required daily for months with wounds involving the larynx or trachea. A number of typical cases are described with the measures applied. Laryngotracheostomy has given the best results. He makes a point of refraining from tamponing the laryngostomy wound until the fifth day. This obviates the necrosis of the cartilage liable with early tamponing.

Revue Médicale de la Suisse Romande, Geneva

February, 1918, 38, No. 2

55 *Obliteration of Superior Vena Cava. R. Favre.—p. 97.
56 *Amebic Dysentery. F. Calame.—p. 125.

55. **Obliteration of Superior Vena Cava.**—Favre describes the clinical picture as observed in four cases of obliteration of the superior vena cava and compared with five on record. His patients were two men of 40 and 55 and two unmarried women of 50 and 56. One of the women had long been insane. All four presented an identical set of symptoms. One case, he thinks, is the first that has been published in which the occlusion of the superior vena cava was secondary to a syphilitic osteitis of the sternum, with ulceration in the esophagus. In the other cases syphilitic phlebitis was manifest. The symptoms are those inevitable from the disturbance in the circulation, the venous stasis in the upper part of the body. The prognosis depends on development of collaterals. Treatment should be begun at the first signs of syphilitic mediastinitis with symptoms on the part of the superior vena cava. The physical and roentgen examination and history of the case, with the serologic findings, confirm the diagnosis when a patient presents cyanosis of face and hands and an elaborate subcutaneous network of veins.

56. **Amebic Dysentery.**—Great improvement was realized under rectal injections of emetin and silver nitrate. With incipient amebic dysentery, emetin attacks and routs out the amebas, but after they have been long in the tissues and are ensconced in the chronic ulcerations, emetin injected subcutaneously cannot reach the amebas. When this stage is reached, local measures are preferable, and he found neosalvarsan in rectal injections extremely effectual in a rebellious chronic case. The blood disappeared from the stools after the first injection and by the third the dysentery seemed to be conquered. The stools have been constantly normal since after years of discomfort and weakness from the amebic dysentery. The man had been brought on a cot to the hospital with twenty-five dysenteric stools a day, and hemoglobin percentage under 28. The disease was of about three years' standing. It is possible that the neosalvarsan or its equivalent might prove still more effectual if the bowel were flushed through an appendicostomy.

Correspondenz-Blatt für Schweizer Aerzte, Basel

March 2, 1918, 48, No. 9

57 *Results of Goiter Operations. Lommel.—p. 273.
58 Diphtheria at Basel. R. Massini.—p. 279.
59 Salvarsan in Amebic Dysentery. F. Heim.—p. 282.
60 Success of Laparotomy plus Tincture of Iodin for Tuberculous Peritonitis. S. Stocker, Jr.—p. 293.

57. **Goiter Operations by de Quervain's Technic.**—Lommel relates that this technic has been applied constantly at the Bern hospital since early in 1914 and with constantly increasing satisfaction. Time has proved that no untoward by-effects have followed in any instance. In more than 50 per cent. of the 190 cases the operation was bilateral, and yet early paralysis of the recurrent nerve occurred in only 0.5 per cent., and in this case proved transient. In three other cases, recurrent paralysis developed several weeks after the operation and proved permanent. On the whole, this de Quervain method of preventive extrafascial ligation of the arteries is styled an essential progress in the technic of strumectomy.

Annali d'Igiene, Rome

Feb. 28, 1918, 28, No. 2

61 *Tuberculosis and Blastomycosis. F. Sanfelice.—p. 41.
62 *Glanders in Felines. M. Carpano.—p. 68.
63 *Color Test of Flour. E. Calendoli.—p. 76.

61. **Tuberculosis and Blastomycosis.**—Sanfelice states that the lungs of tuberculous cattle constantly contain blastomycetes and other fungi. Among the blastomycetes are some species pathogenic for laboratory animals and fowls, and in shape and cultures not distinguishable from the *Saccharomyces neoformans*. Associated with tubercle bacilli, animals inoculated died more rapidly than the controls inoculated with the tubercle bacilli alone, and the tissues show both diffuse tuberculosis and blastomycosis.

62. **Glanders in Felines.**—Carpano found signs of acute glanders in the lungs of a tiger dying in captivity at Rome, and others have reported similar findings in lions and cats. The zoological gardens at Rome recently had an epizootic of acute glanders among the lions and tigers but the other animals escaped. Twelve of the large felines were affected and a number died. Cats inoculated from them developed the same set of symptoms in from three to five days, while other cats infected naturally from these cats showed an incubation period of six or seven days. The temperature, however, ran up the end of the fourth day.

63. **Color Test of Flour.**—Calendoli adds a pinch of wheat flour to a little concentrated hydrochloric acid. The color of the fluid changes to violet in proportion to the freedom from bran particles and of flour from other grains. The change of tint is complete in one or two hours and persists unmodified for twenty-four hours. Other flours and bran change the tint to brown.

Jan. 27, 1918, 39, No. 8

66 Shrapnel Ball in Right Heart. G. Pisano.—p. 75.

64. **Purpura from Quinin.**—Samaja says that malaria is the one disease encountered most frequently now in the Italian military hospitals. Among 417 patients in his service at Bologna, 244 had malaria. Among the symptoms of intolerance of quinin, occasionally noted, hemorrhagic purpura was not exceptional, but the dose of quinin usually was large when this by-effect was observed. In one case, however, the severe purpura developed after doses of only 1 mg. per kg. of body weight. The attacks of hemorrhagic purpura followed whether the quinin was given by the mouth or subcutaneously, and in constantly smaller doses down to 0.10 gm. but the intensity of the purpura was less pronounced with the smaller doses.

Riforma Medica, Naples

Feb. 9, 1918, 34, No. 6

67 *Paralysis from Shell Air Shock. L. Gatti.—p. 102.
68 *Precipitation Reaction in Syphilis. G. Bastogi and L. Corridi.—p. 107.

Feb. 16, 1918, 34, No. 7

69 *Functional Disability after War Wounds. R. Falcone.—p. 122.
70 *Infectious Jaundice. E. Salvaneschi.—p. 126.
71 The Trigeminal Syndrome. E. Aievoli.—p. 128.

67. **Paralysis from Air Concussion.**—Gatti reports a case of extremely acute paralysis with atrophy following close on explosion of a large bomb without actual contact. The tetraplegia was of the type of anterior poliomyelitis, and Gatti assumes that the anterior portion of the spinal cord had been injured by the air contusion. He knows of only one similar case on record. The paralysis and the atrophy gradually invaded all the musculature except in the head and neck, but there were no sensory disturbances and the sphincters behaved normally. Instances of traumatic anterior poliomyelitis are on record. Some injury of the blood vessels in the bulbar region is evidently responsible for the whole set of symptoms.

68. **Bruck's Precipitation Test for Syphilis.**—Bastogi and Corridi applied Bruck's nitric acid test to serum from 113 syphilitics or suspects and to fifty-five nonsyphilitic patients or healthy persons. Positive findings were obtained nearly as often in the nonsyphilitic as in the syphilitic, while a negative response was common with known syphilis. This unfavorable verdict corroborates Stillians' (The Journal, Dec. 15, 1917, p. 2014).

69. **Functional Disability After War Wounds.**—Falcone discusses in turn the proper treatment when the war wound leaves vicious consolidation, ankylosis, pseudarthrosis, paralysis, retraction of muscles or tendons or chronic edema. He insists that all these are avoidable, and that, once established, physical measures are destined to fail to cure unless they are applied or reenforced with zeal and energy by the patient himself. But this cooperation on the part of the patient cannot be secured with the wounded soldiers; they are apathetic if not directly hostile to measures to cure them up quickly. Hence Falcone urges that physical measures should be applied from the first, while the man is still in the hospital and under medical control. It does no harm to flex the fingers or massage the soft parts or apply electricity, even if the bone below is not entirely healed. The crippling deformities can often be traced to lack of care during the healing—physical measures cannot be ordered like so much quinin, but must be adapted to the individual case and constantly supervised, and be applied during the tractable phase before the parts grow stiff and rebellious. He advocates legal authority for correction of deformity by some insignificant operation, such as tenotomy to cure talipes equinus. The men now refuse to permit such interventions as they prefer the crippling to a return to the front line. He suggests that surgical centers might be equipped each for some special intervention in this line by specialist surgeons, to which the men could be referred before their deformity becomes irreparable and throws them a burden on society for life.

70. **Infectious Jaundice.**—Salvaneschi analyzes the clinical findings in 276 cases of spirochete jaundice in the troops of the advanced line. The gallbladder was always enlarged and tender and the liver was usually much enlarged from the very first. The spirochetes seem to be found constantly in the urine, and hence the close quarters in the trenches favor transmission of the infection in food and water. The spirochetes may also find their way into the body through erosions.

Rivista di Clinica Pediatrica, Florence

February, 1918, 16, No. 2

72 *Visceral Syphilis in Young Infants. G. Menabuoni.—p. 57. Commenced in No. 1, p. 1.

72. **Visceral Syphilis in Infants.**—Menabuoni reports the clinical history of twenty-two cases of inherited syphilis localizing in the viscera in children less than a year old, with the necropsy findings in a number. The spleen and liver were enlarged in all. In seven of the eight whose blood was examined, the leukocytes ranged from 1,400 to 24,000. He compares the findings in the various organs with those on record. All show that the lesions vary according to the period of fetal existence when they began, but they are all of two types, either a hyperplasia of the tissues of mesodermic origin, starting from the vessels and entailing sclerosis and atrophy, or a reaction and changes in the noble elements of the organ arrested in its development, entailing cystic formations and foci of necrosis. The vessels are always damaged, the spirochetes injuring them first and spreading from them to the surrounding tissues. The infants born dead or dying soon after birth show the various steps of this spirochete septicemia.

Anales de la Facultad de Medicina, Montevideo

December, 1917, 2, No. 11-12

73 *Alternate Traumatic Paralysis. A. de Castro.—p. 697.
74 *Diabetes Insipidus and the Pituitary. P. Lereboullet.—p. 712.
75 Study of Arterial Blood Pressure. A. Martinet.—p. 742.

78 *The Cholesterol Index. L. A. Surraco.—p. 778.
79 *Amputation of Uterine Cervix. M. B. de Bengoa.—p. 819.
80 *Gastric Fistula. C. Nario.—p. 823.

73. **Traumatic Alternate Paralysis.**—De Castro gives an illustrated description of two cases of what he calls the *Millard-Gubler* syndrome, the arm, leg and face on one side being paralyzed as also the external oculomotor muscles of the eye on the other side. The bullet or spike had injured the pons and he describes the mechanism, citing further Nodet's case in which the prong of a pitchfork had entered the chin and pierced through to the skull, back of the vertex. Notwithstanding the long path of the prong, no symptoms were observed from it except the alternate paralysis of the *Millard-Gubler* type, resulting merely from the injury of the pons on its way.

74. **Diabetes Insipidus and the Pituitary Body.**—Lereboullet has long proclaimed the advantages of pituitary treatment in cases of diabetes insipidus. The pituitary lesion may act directly or by compression of nerve tissue in the vicinity, or changes in the nerve tissue may secondarily affect the pituitary. He gives the ultimate outcome of a case previously published in which the man of 24 had seemed to stop developing at 14 and presented eunuchoid infantilism with permanent polyuria, falling out of the teeth, and eruptions suggesting that besides the diabetes insipidus there were certain elements of diabetes mellitus. Alimentary glycosuria followed even 50 gm. of glucose. The output of urine was from 6 to 10 liters in the twenty-four hours and pituitary treatment by the mouth did not modify it, but subcutaneous injection of 0.05 gm. pituitary extract, corresponding to half of the posterior lobe of a beef pituitary body, caused the urine to drop to 1 or 2 liters; appetite and sleep returned and the young man felt better, but this effect never lasted over twenty hours. He finally made the injections himself and kept them up for months. If they were suspended for twenty-four hours the polyuria returned. After two years of this he had gained 3 cm. in height, the hair on his body had grown somewhat, and the testicles had descended, and there were erections and ejaculations—phenomena never known before, but old tuberculous lesions in the lungs and around the anus had continued to progress, and proved fatal a year or so later. In these and similar cases of *infantilisme reversif*, the thyroid seems to be involved but to a less extent than the pituitary. Syphilis is evidently a factor in certain cases. Sourdel has reported a case in which, twenty years after syphilis had been contracted at 25, the man developed atrophy and infantilism of the genital organs plus extreme polyuria. Other cases are cited to sustain this relative frequency of diabetes insipidus with reversive infantilism, and the frequency of syphilis as the main factor in the disturbance in pituitary functioning responsible for the phenomena indicating dystrophy. Diabetes insipidus is also encountered at times with the adiposogenital syndrome, but less often than with congenital or reversive infantilism. Still more conclusive in this line is the development of polyuria in the course of cancer of the breast and occasionally elsewhere, explained by metastasis in the posterior lobe, found at necropsy. The most convincing argument, however, is the efficacy of pituitary treatment. Although the action lasts only for twenty-two hours, even this gives great relief, whether its action is specific or merely symptomatic.

76. **Mineral Metabolism.**—Lematte discusses the ratios between the intake of minerals in food and the elimination in the urine, and the action of the different segments of the digestive tract on the combinations of minerals. It seems to be settled that the reciprocal saturations of oxids and acids occur according to the laws of thermochemistry. He states that the phosphate or biphosphate content of the urine depends on the quantity of hydrochloric acid liberated by the gastric secretion. The phosphate content of the urine is thus an index of the chlorhydria of the stomach. The liberation and oxidation of sulphur occur in the intestines parallel to the liberation of the amino-acids. Other things being equal, the proportion between the sulphur of the sulphates and that of the sulphoconjugates of the urine is determined by the pancreatic and intestinal digestion.

77. **Liver Abscess with Ulcer of the Stomach.**—In Navarro's two cases the liver disorder dominated the clinical picture, and after opening an abscess in the liver or after repeated punctures releasing blackish blood without pus, the ulcer in the anterior aspect of the stomach healed spontaneously, that is, under the influence alone of the exposure to light and air during the laparotomy. In neither of the cases was the gastric ulcer suspected before the operation, and it was not found until necropsy in one case. In the other the gastric ulcer region was solidly adherent to the inflamed liver but no abscess had formed as yet.

78. **Cholesterol Index.**—For the last year, Surraco has been determining the cholesterol content of the blood in all cases of stenosis of the urethra or enlarged prostate. This cholesterolemic index reflects the state of the organic defences, and when determined in series throws light on the prognosis. A cholesterol content below 1.2 gm. indicates something wrong, showing extreme weakness of the organic defences. Above 2 gm., it indicates chronic slow infection or more or less pronounced uremia. Below 1 gm. the prognosis is very grave. Cases are described which confirm these statements. The normal range is apparently from 1.2 to 1.9 gm.

79. **Amputation of Uterine Cervix.**—De Bengoa has modified Bonney's technic for amputation of the cervix so that no raw surface is left exposed while the shape of the cervix is normal. The result was a complete success in the six cases in which he has applied this technic to date. After the amputation he runs a stout catgut suture around below the mucosa, like a garter, the ends brought out at one side. Then the two suture threads of Bonney's technic are passed through the tissues, at some distance back, enclosing the raw margin on each side. The garter suture is drawn up and tied; this restores the natural shape and size of the cervix opening. *Then pulling on the two Bonney threads draws this raw edge* inward for some distance, and when the Bonney threads are tied the cervix is left like the mouth of a muff, nothing showing but *sound tissue.*

80. **Gastric Fistulas.**—Nario advocates continuous aspirating siphonage action through the skin stomach fistula. In the two cases described, the fistula left after gastrectomy or cholecystectomy began to heal almost at once when this was done.

85 *Massage of Lacrimal Sac. N. da Rocha.—p. 26.

81. **Mutilating Leishmaniosis.**—The upper lip and palate had been destroyed and the adjoining soft tissues had hypertrophied and hung down like broad tusks *to below* the chin. Under antimony treatment the extensive lesions healed and a plastic operation gave good results. The treatment was begun with intravenous injections of 0.01 gm. of tartar emetic in 1 c.c. of distilled water, and the lesions were laved with the same. After thirteen daily injections the dose was increased to 0.05 gm. and ten injections were given at three day intervals. The dose was gradually increased to 0.07 and 0.08 at two or four days interval, and the tolerance was apparently complete, but a violent reaction followed a single dose of 0.10 c.c. By this time healing was complete.

82. **Cancer of the Liver in Youth.**—The boy of 14 had three healthy brothers and sisters and the father is healthy; the mother died from hemorrhage at his birth. After an attack of pneumonia at 14, the boy suffered from severe gallstone colics and some ascites developed. He passed two gallstones but the pains in the liver kept up and the much enlarged liver felt hard but *uniform.* There was no fever at any time. The laparotomy revealed cancer of the liver and the boy died before the week was over, about forty days after the first symptoms. There was nothing to suggest syphilis in the boy or family. Cholelithiasis frequently precedes cancer of the liver; ascites does not accompany gallstones, as a rule. Fever is regarded as an important sign of cancer of the liver but it was not present in this case. The diuresis had kept up well.

85. **Massage of Lacrimal Sac.**—Da Rocha insists on teaching the patient to massage the region several times a day, always back of the crest of the bone. The massage restores elasticity to the stretched walls of the lacrimal sac, and the rubbing of the walls together clears the passage of accumulations. If catheterization is necessary, a few days of preliminary massage facilitate it and enhance the effect.

95 Advertisements in the Medical Press. G. F. Arreu.—p. 137.
96 The Physician as a Civic Leader. A. Galarreta.—p. 140.

92. **Typhoid in Cuba.**—Lebredo remarks that while Cuba has conquered yellow fever, smallpox and bubonic plague, yet it keeps on paying a high tribute to typhoid. In 1917 there were many cases in different provinces throughout the island. He insists that every typhoid case should be taken to a hospital as the only means to insure adequate prophylaxis. In fact, every pyrexia of long duration or with infectious gastro-intestinal symptoms should be removed to the hospital, or the Public Health Service should take the prophylaxis in the home into its own hands.

93. **Hypernephroma.**—The man of 50 had had pains and hematuria for seven months when the right kidney was removed on the assumption of hypernephroma. The tumor weighed 420 gm. Two months later pains in the left shoulder attracted attention and a metastatic tumor was found at the head of the humerus. After disarticulation there were no further symptoms for a few months. Then metastasis in the femur compelled amputation in the upper third. There were no further symptoms during the following two years, but the man then succumbed to the effects of morphin addiction. Metastasis of this form of cancer generally locates in the lung, liver or long bones, and many cases of supposed primary sarcomas in these regions were rightfully metastasis from undiagnosed hypernephromas. Hochenegg has reported metastasis ten years after nephrectomy for the primary tumor. In the case described, the metastasis in the shoulder was evidently installed before the primary tumor had been discovered and removed. The second metastasis developed at a point where the femur had just been fractured.

99 *Practice of Medicine in Cuba. D. T. Lainé.—p. 131.
100 *Intoxication from Eating Fish. H. Seiglie.—p. 141.

97. **The Latin-American Medical Press.**—Fernandez says it is a capital defect of Latin races to shrink from writing for publication, and consequently the fruits of their experience perish with them. He warns the medical students of the day to beware of the *habito latino del mutismo.*

98. **Different Forms of Ileus.**—Yaniz reports merely some unusual forms which he has encountered, calling attention to the necessity for differentiating ileus from paralysis of the bowel. This latter requires merely medical measures. After operations on the bowel he often gives pituitary extract to promote peristalsis, and advocates it also in the medical cases, with massage of the abdominal wall.

99. **Practice of Medicine in Cuba.**—Lainé relates his impressions when he returned to Cuba twenty years ago to practice medicine after studying in the United States and practicing several years in Philadelphia. At that time the practice of medicine in Cuba was modeled on the European, and scarcely anything was known of American medical and surgical methods, but now, he says, the majority of Cuban physicians are in close touch with physicians and surgeons of the United States. They are familiar with American medical literature, and they use American drugs. In the United States, he adds, a physician called in consultation will never allow the family to transfer the patient to his care, but this has been done in Cuba. In regard to drugs, he remarks that no country in the world uses such an enormous quantity of proprietaries in proportion to size and population as Cuba. This is due either to ignorance of fundamental therapeutics or to heedless indifference. Another peculiarity of practice in Cuba is the large doses of calomel used. It is not uncommon to see doses of 0.10 or 0.20 gm. of calomel prescribed for small children. Strychnin, on the other hand, is given very cautiously; few venture to order more than 1 mg.

The climate of Cuba is decidedly enervating for persons from the North, for women especially. After one or two years' residence in Cuba the majority of persons from the United States have to return to a cooler climate to recuperate. The Cuban diet contains an unusually large proportion of meat, and fresh vegetables are very scarce—this cooperates with the climate and the lack of exercise in undermining the health. He estimates that instead of the usual 10 per cent. of proteins in a diet of 2,500 calories, the Cubans have 60 per cent. proteins, and mostly served fried. The special features of the morbidity of Cuba that have impressed him are the rarity of acute lobar pneumonia and of acute articular rheumatism, and the mildness of the children's diseases, whooping cough, measles and scarlet fever. Dengue is extremely common, and it can be diagnosed from the first by the spontaneous pain in the eyeballs and the pain on pressure. The pains increase as the eyeballs are rolled up or down. The rash is manifest the third or fourth day, especially in the face, but it may have to be sought for in a good light.

In conclusion he urges the profession to overcome the extreme conservatism of the Latin-American, to cultivate the spirit of union in the profession, and overcome the tendency to distrust each other. He relates that for years he was the only surgeon in Cuba that used gloves in operating, and it is only about three years since they have come into general use. For six years he has been giving antityphoid vaccine to his family and patients but its use has not become general in Cuba. He adds that for more than a year he has been using nitrous oxid for the anesthetic in surgery and obstetrics, but no one else is adopting it. His thirty years of the practice of medicine, he declares, have been a constant struggle to keep not too far behind the progress of medicine and surgery; in other words, his life as a medical student has never stopped a moment. Many years ago he became convinced that no one man can master all the medical sciences, and he never hesitated to call on specialist aid as needed in the individual case. "Our profession cannot get along without mutual aid. We must be honest with ourselves, and, recognizing our limitations, learn to know when to depend on others."

100. **Poisoning from Fish.**—Seiglie describes the set of symptoms known as *ciguatera*, caused by eating fish. Some fishes are naturally poisonous, others only when they reach a certain size or age. He lists them all and comments on the uncontrollable vomiting, the colics, tenesmus and dysenteric or choleriform passages, with or without nervous disturbances. Scotoma, diplopia and sometimes transient blindness and contraction or dilation of the iris are common, and ptosis of the eyelids. The pulse is small and irregular, the tension and temperature subnormal. There is almost always a rash, with desquamation, and sometimes the hair and nails drop out. Lavage of the stomach, effervescent mineral waters, scraps of ice and champagne may be indicated, with morphin if there is much agitation. The antitoxic action of the liver should be stimulated and the bowels disinfected, with salol, sodium salicylate, etc., and the emunctories stimulated with copious ingestion of water with 5 per cent. lactose, or infusions.

106 Hypnotism, Idealism and Materialism. F. de Courmelles.—p. 54.

102. **Tuberculosis in Spaniards.**—Coni was impressed with the large percentage of native Spaniards in his medical service at Buenos Aires although the Italians in the general population far outnumber the Spaniards. He noted also the large percentage of young married women born in Argentina of Spanish parents. He cites some international figures which place Spain at the head of the list of tuberculosis mortality. His table shows 5,000 deaths from tuberculosis in Spain per million inhabitants; France comes next with 3,900; then Portugal, 3,800; Austria, 2,700; Germany, 2,200; Argentina, 2,000; Italy, 1,800, and England, 1,300. In Argentina the Italians generally drift to outdoor occupations while the Spaniards are employed more in hotels, restaurants and stores.

104. **Chronic Arsenic Poisoning.**—The man of 39 has presented for three months symptoms of pseudotabes from peripheral polyneuritis. Zayas ascribes the syndrome to poisoning from the arsenic with which the drinking water in the Bell Ville region is known to be impregnated, as recently mentioned in these columns. This case developed about twenty miles from Bell Ville, showing that the dangerous water affects a larger area than hitherto assumed.

107. **Endemic Goiter in Spain.**—In the high mountain valleys in the province of Avila goiter is endemic in man but the trout caught in large numbers in the streams for the market seem to be free from it. Goyanes' studies of these endemic foci have convinced him that an infectious factor is certainly involved. Improved hygiene seems to be reducing the prevalence of goiter and cretinism in these old foci. The thyroiditis responsible for the goiter develops in phases, with intermissions.

109. **Prophylaxis of Recurrence of Cancer.**—Morales in commenting on a few cases of cancer of the penis says that recurrence is almost certain when the penis alone is amputated. On the other hand, recurrence is almost unknown when the entire external genital organs are removed. With complete castration, nothing is left to keep up dangerous stimulation or irritation which otherwise is liable from the testicles.

119 Tropical Ulcer in the Troops. B. A. Volter.—p. 571. Continuation.

112. **Tumor in the Breast from Shell Air Shock.**—Velyaminoff's case was in his own person, and he relates how the first year or two of the war had passed without any special disturbance. He was accustomed to artillery fire, but then came a period when he was stationed in a small, one story building where orders were issued, the men paid, plans drawn and reports presented while all the time the place was being bombed by aeroplanes. The bombs caused such explosions that the walls shook and the plaster dropped off as if in an earthquake, and this kept up not for minutes but for hours at a time and often in the night. Some days the aeroplanes dropped as many as 120 bombs in the morning and 60 in the afternoon. As the walls of the house rocked, he found that his chest wall shook too, as he confirmed by the flame of a candle. Sometimes the explosions were so powerful that the men in the small shelter with him were knocked down by the air concussion and he was knocked off the bench on which he was sitting. He is a man of 62, and he noticed a disagreeable sensation in his left chest as these explosions occurred. The nipple grew very tender and felt as if there was an extensive burn in the region, and the left breast developed a tumor. He attributes all this to the repeated air contusions. The aspect of the mammary tumor was exactly like that of the so-called hysteric tumors, but his general condition precluded the assumption of hysteria. The left arm felt numb, or paresthesias, at the same time, and these phenomena and the size of the tumor varied in intensity from time to time and parallel, during the six weeks he was subjected to this aerial bombardment. During the whole period he felt a little depressed but this was more from responsibility and overfatigue than from a sense of personal danger. It was very annoying to have to be interrupted so constantly in one's work and be forced to seek shelter, wasting precious time. He theorizes to explain the mechanism of the disturbances, ascribing them to the shaking up of the nervous system and of the glands with an internal secretion, the result being equivalent to a "chemical trauma."

117. **Ameba Found in Trench Fever.**—Triudin is convinced that the infectious disease he describes, known as "trench fever," is a disease *sui generis*. Also that the ameba he found in the blood stands in some causal relation to it. He found the protozoon in 75 per cent. of his twenty-four cases, but exclusively during the first three days of the disease. The blood showed the characteristics of a severe blood disease. Coagulation was retarded; in some it began at the tenth minute, in others not until the twenty-third. The average was eighteen minutes.

121 Standardization of Lobelia. C. de L. Van Wijngaarden.—p. 347.
122 *Medical Cure of Anal Fistula. G. H. J. Peter.—p. 352.

120. **Practical Aspects of Acclimatization in the Tropics.**—De Langen and Schut practice in the tropical islands of the Dutch East Indies, and they call attention to their constant finding of characteristic changes in the blood of persons coming to the tropics to live. They insist that the intensity of the light, the content in chemical rays, are no greater in the tropics than in Europe, so this cannot be responsible for the modified physiologic chemistry in the tropics. They found that the average sugar content of the blood of natives of Java was 0.15 per cent. and of Europeans residing in Java, 0.16 per cent. In corresponding research on Europeans in Europe they had found 0.093 per cent. as the average of the reducing substances in the blood, with the Bang micro test, which are regarded as representing the sugar content. The content in the blood of rabbits, guinea-pigs and hens in Europe averaged respectively 0.10, 0.11, and 0.15 per cent., while in Batavia these averages were 0.16, 0.15 and 0.26 per cent. McCay has also published findings of blood sugar in the natives of Bengal 50 per cent. higher than the average in Europe. He did not investigate the sugar content in Europeans residing in Bengal, and ascribed the high findings in the natives merely to their predominantly carbohydrate diet, and not to the tropical climate. The cholesterol content of the blood, on the other hand, is abnormally low. In the natives the cholesterol content averages only half of the average in Europeans in Europe; in twenty natives the average was 0.88 gm. per liter of blood serum while the average in Europe is said to be 1.5 to 1.75. European immigrants in Batavia also show a low cholesterol content. De Langen and Schut did not investigate the calcium content of the blood, but they suggest that as this is always found abnormally low when there is hyperglycemia, we can almost take it for granted that there is a deficit in calcium. A number of facts sustain this assumption, as they relate; among them the tendency of tuberculosis in the tropics to be exclusively of the exudative type, without calcium shadows in the lungs, and calcium deposits in arteriosclerotic vessels are rarely found in cadavers.

The primal cause for these differences between the blood condition in Europe and in the tropics, they ascribe to the heat. The humidity may also be a factor. The hypothesis is advanced that the heat exaggerates the tonus of the sympathetic nervous system. If we can accept this, all the phenomena are explained as the logical and inevitable sequence of high sympathicotony, acting on the suprarenals, etc. The writers' research on animals, artificially stimulating the sympathetic nervous system, reproduced the whole sequence: the glycogen in the liver was mobilized, the sugar content of the blood ran up high, and the organism sought to throw off the excess of sugar in the circulating blood. This it can accomplish by eliminating it through the kidneys or by burning it up. They found that when there was not pronounced glycosuria, the animals developed fever. The "low fever" of the tropics may have a similar origin. This suggested that in infectious diseases the bacterial toxins may first irritate the sympathetic system. This entails hyperglycemia, and the fever follows on the hyperglycemia. They found this sequence marked in malarial patients; first the increase in the sugar content of the blood, and then, not until an hour or two later, the fever of the malarial attack. In one case the sugar content ran up on a day when the attack was not expected, but the fever followed the hyperglycemia. On the other hand when, under quinin, the blood sugar kept within normal range, the expected attack failed to develop. Among the other data cited is that the high sugar content of the blood declines when the persons change from the lowlands to the cooler mountain climate in the islands. Also that the hyperglycemia is evident in persons coming to the tropics even in less than a week after their arrival, an argument in favor of its nervous origin.

Persons inclined to sympathicotony, to diabetes, to renal glycosuria and to tuberculosis should be advised against life in the tropics, at least in the lowlands. On the other hand, a healed apical catarrh, or other tuberculous pulmonary lesions need not deter from residence in the tropics if the constitution is of a pronounced vagotonic type. The possibility of benefit from treatment with calcium to regulate the unstable sympathetic nervous system is also suggested. Neuritis and polyneuritis are common in Java, and the hyperglycemia may predispose thereto. The tubercle bacillus in the tropics thus finds high sugar content in the blood, low calcium content and low cholesterol content—all three are factors which directly favor its proliferation and a rapid course of the disease. Chronic tuberculosis is rare in the Dutch East Indies outside of the mountain districts.

122. **Treatment of Fistula of the Anus.**—Peter filled the rectum with 500 c.c. of a solution of boric acid. Then he injected into the fistula 0.3 c.c. of tincture of iodin. This was repeated three times in five weeks, followed each time with bismuth, opium and fasting. The long rebellious, suppurating fistula began to heal at once, and the cure was soon complete. The preliminary filling of the rectum with

fluid allowed the strong tincture of iodin to act on the fistula lining but diluted it at once as it entered the rectum, so that there was not the slightest irritation of the mucosa.

Hospitalstidende, Copenhagen

Feb. 13, 1918, **61**, No. 7

123 Electric Light Baths in Rhinolaryngology. O. Strandberg.—p. 193.
124 *Swine Plague in Man; Three Cases. L. Thomsen.—p. 203.

124. **Swine Plague in Man.**—Thomsen has encountered three cases of a lesion on the hand, resembling erysipelas, with lymphangitis running up the arm, nausea and fever. The first patient was a veterinarian and the diagnosis of swine plague was followed by injection of 10 c.c. of the antiserum. In less than an hour the malaise had subsided and in four days recovery was complete except for a little stiffness in the arm. The man had been giving the antiserum to a sick hog four days before his own sickness. The farmer's wife who had helped to hold the hog during the injection got some blood on her hand and a small lesion developed. After failure of other measures, injection of 10 c.c. of the antiserum cured the lesion in three days. In another family a hog taken suddenly sick was slaughtered, and the farmer's wife developed the same clinical picture as in the first two cases. It dragged along untreated for two months and then subsided. One meal was made from the pork but all eating it were taken with severe diarrhea and the rest of the carcass was buried.

125. **Goiter in Norway.**—Kjølstad relates that goiter is extremely prevalent in the Telemarken district in southern Norway, southwest of Christiania. In one school at Lunde 80 per cent. of the children have goiter. Most of the goiters are of the atoxic type, and they nearly always subsided under iodin. He never noted any symptoms of intolerance in children, but several adults developed symptoms of thyrotoxic action, and one girl of 15 seemed to have had her simple goiter transformed by the iodin into exophthalmic goiter, although the medication had been moderate and the intermissions long. The iodin seems to act on the hyperplasia of the parenchyma; colloidal nodules and cysts are comparatively little affected by it. The patients must be warned that iodin treatment of goiter takes a long time; too vigorous treatment he regards as dangerous. The dosage he prefers with colloidal goiters is 0.10 gm. potassium iodid every other day for two weeks, and then suspension for three weeks and resumption for two weeks, and so on. With merely parenchymatous goiters, he follows the Kocher method of anointing the goiter with an iodin-potassium iodid salve, using from 1 to 3 gm. daily for two weeks at a time, then suspension for three week periods. Salve is better than the tincture, as it spares the skin. No other drugs or other treatment have proved effectual in his experience. Roentgen treatment is liable to injure the still intact portions of the gland. With symptoms of exophthalmic goiter or other signs of excessive functioning of the thyroid, sodium phosphate in a 5 per cent. solution seems to give good results—a tablespoonful four times a day, in milk. The basis for this treatment is the antagonism between iodin and phosphorus in the action of the thyroid gland (A. Kocher). He has often seen the goiter subside under this treatment, especially when the patients gave up work and went to the hospital. When all else fails, surgical measures should be advised before parenchymatous degeneration appears.

126. **Iodiosyncrasy to Mercury.**—Gjessing's patient was a quadripara who exhibited a violent reaction to injection into the nose, to act on the lacrimal sac, of 1 c.c. of a 1 per 10,000 solution of mercuric chlorid containing a little epinephrin. Possibly her recent conception may have increased the susceptibility, but the case teaches that before using mercury it is well to bear in mind the possibility of an idiosyncrasy, particularly in persons known to develop urticaria on slight excuse.

127. **Miostagmin Reaction with Cancer.**—Salvesen has been giving the miostagmin reaction a trial and found it disappointing. All the cancer patients gave a positive response, but so did all but five of seventeen other patients free from malignant disease. Among twenty-four serums tested from patients with different diseases or healthy controls, all but five gave a positive response. It cannot be said to have much differential value, therefore, although O. Wissing has recently been lauding it as a simple and dependable test for revealing cancer, especially cancer of the digestive tract. He uses a Traube stalagmometer with Izar's antigen, a solution of 2 gm. each of linolic acid and ricinolic acid in 100 c.c. of absolute alcohol.

130. **Cancer as an Economic Loss.**—Gade relates that in a recent ten year period, men formed 48.9 per cent. of the total cancer mortality in Norway, while the men represent only 45.6 per cent. of the total population at the age of 35 and over. Cancer therefore seems to be somewhat more prevalent in men than among women in Norway. He calculates the economic loss to the country of the average loss of 1,080.6 men each year from cancer, and the loss from tuberculosis, pointing out that the tuberculosis mortality includes mostly men at their highest working capacity while cancer is more of a biologic phenomenon, associated with old age, as human beings have got to die of something.

133 Chloroform Internally for Gallstone Colic and Subcutaneously for Sciatica. H. R. Magnus.—p. 178.

131. **Pathologic Wanderlust.**—Helweg says that the morbid impulse to go away, without special motive that others can see for the change, is a common feature of epilepsy, but is not confined to this disease. The French regard this *automatisme ambulatoire* as a manifestation of hysteria. In Danish literature Helweg has found records of only four cases, and nowhere has he been able to find records of this morbid tendency in degenerates other than epileptics and the hysteric. He describes six cases in detail in which degenerates displayed at times this morbid wanderlust although conscious of what they were doing. In five of the cases there was a history of a fall on the head and in a number of cases on record there is casual reference to trauma of the head. One patient was a young woman of a well-to-do family with some inherited mental taint. She seemed normal as a child but met with two accidents injuring the head and not long after the second one began to wander away from home. Later she left home again and again, living at hotels in the town, pawning her belongings and sometimes stealing to get the money. On some of her wanderings she was accompanied by a man, a chance acquaintance, but there did not seem to be any erotic tendencies, and occasionally she had no clear remembrance of the times she was away from home. Placed in an institution for mental disease, nothing abnormal otherwise could be detected in her.

The psychopathic degeneration responsible in Helweg's cases for the wanderlust is about as common in women as in men, but in women it is not fanned into a flame by abuse of alcohol, and it usually manifests itself in them in other ways than in this tendency to vagabondage. Usually some quarrel or other unpleasantness brings the impulse to run away. In one of the cases the man was in military service and repeatedly ran away to visit his wife. The pathologic wanderlust is practically the same thing whether it is result of epilepsy or hysteria or of dementia praecox or psychopathic degeneracy. There is no need to invent special names for it like Donath's "poriomania" and Joffroy's "dromomania."

THE PRECIPITIN TEST FOR BLOOD*

LUDVIG HEKTOEN, M.D.
CHICAGO

The study of immunity as manifested by the reactions of the animal body to microbes, toxins and protein materials in general has given us many tests of great value. The phenomena of agglutination, of complement fixation, of altered reactivity, of opsonification and of serum precipitation have all been put to practical use in tests, some of which are used every day throughout the civilized world. Speaking generally, the only way now known to trace protein substances back to their source, that is, to the species from which they come, is by means of their immune reactions; and in the case of blood and other animal products, practically the only method for purposes of biologic differentiation is the precipitin test. Because the determination of the ultimate source of blood spots and stains often is vital to the administration of justice, the precipitin test is of special forensic value and interest, and it is primarily from the medicolegal point of view that I wish to discuss the test at this time. The test has been used in this country for the identification of blood for forensic purposes since it was introduced, although probably not so widely as it should or might have been; but it does not appear that any standard method of procedure even with respect to certain essential points as yet has become established, and there are hardly any adequate detailed descriptions of the test.[1]

The precipitin test rests on the fact that when a suitable animal is injected with foreign protein, its serum, when mixed with a solution of the foreign protein, will form a precipitate. This reaction is due to the accumulation in the blood of the injected animal of newly produced substances, which are called precipitins. By foreign protein is meant protein from some other source than the species to which the animal injected belongs. Thus serum for the identification of blood is obtained by injecting rabbits (the animal nearly always used for this purpose) with the blood or serum of an animal of a different species, the exact species in each case depending on the kind of blood one intends to test for with the resulting precipitin serum; for the action of precipitin serum is limited to proteins of the same kind as those that were injected; indeed, the precipitin test owes its practical value to this fact.

THE PRODUCTION OF PRECIPITIN SERUM

At present we know of only two animals that are good and suitable precipitin producers for practical purposes, the rabbit and the domestic fowl. Hitherto the rabbit has been used almost altogether, Sutherland[2] in India being the only one to use the fowl on a large scale. Of the two the fowl seems to be the more ready and reliable producer, but fowl serum must be handled with special care because of the tendency under certain conditions to give nonspecific reactions. So long as rabbits are plentiful, it would seem best, at least in this country, not to change to the fowl except for special purposes, as when it is necessary to test directly for rabbit blood. In any case young, healthy, previously unused animals should be selected; they should be kept under hygienic conditions and given enough of good food. It is always advisable to inject several rabbits at the same time, especially when antihuman precipitin is to be produced, because in some rabbits the response to the injection may be rather insignificant.

Either whole blood, defibrinated or citrated, or serum may be injected; in my experience the results have been about the same. As we deal with whole blood in the identification of blood spots, there may be advantage in using antiserum produced by whole blood; this may be counterbalanced, however, by the fact that serum is somewhat richer in proteins. Blood should not be injected intravenously because of the danger of sudden death. To produce antihuman precipitins, albuminous urine and various transudates have been injected also; but the best results are secured from blood or serum, and in these days when patients are bled so frequently from the veins for diagnostic tests, there is no difficulty in obtaining the required human blood or serum, which need not be absolutely fresh provided it is free from bacteria. The injection of rabbits with washed human corpuscles, now so often practiced in order to produce hemolytic amboceptor for the Wassermann test, not infrequently gives as a by-product in sufficient concentration for practical use specific precipitins for the proteins in human blood.

In the immunization of rabbits, good results may be obtained with various methods that differ more or less in minor details. The tendency is to inject smaller quantities of blood or serum than formerly. Several rabbits should be injected at the same time because, as stated, there is great individual variation in the power to produce precipitins, especially antihuman. A good way is to inject from 1 to 2 c.c. of serum intravenously, repeat in six days or so, and then after six or eight days to inject 4 or 5 c.c. intraperitoneally. Or from 5 to 6 c.c. of blood or serum may be injected intraperitoneally four or five times at intervals of six days or so. In either case the serum should be tested about nine to twelve days after the last injection, because about this time the precipitin content reaches its high point; as it remains at this point only a few days, the tests must be made promptly so that if the serum is found to be potent, goodly quantities may be collected while the precipitin still runs high. It has been found that the danger of death from anaphylactic reactions when the last injections are given may be avoided by first giving a small so-called desensitizing injection, 1 or 0.5 c.c., intravenously or intraperitoneally.

A more rapid method of immunization consists in giving intraperitoneal injections of increasing quantities — 5, 10, 15 c.c. — on three successive days. The same total quantity of antigen injected at one time may also give good results. As a rule the precipitin in either case reaches its acme about the twelfth day or thereabouts. If serum is used, the injections may be made intravenously. In my experience,[3] this so-called rapid method yields more reliable results with beef, sheep, horse, swine, cat and chicken blood or serum than with human, and it is probable that in the last case the desired result will be obtained oftener by repeated injections at longer intervals.

In the case of the fowl a single intraperitoneal injection of 20 c.c. of blood or serum usually in ten or twelve days yields a precipitating serum of sufficient strength for practical purposes.[4]

It is not necessary now to describe the details of injections, bleeding, and collection of serum. At every step scrupulous effort must be made to prevent contamination; contaminated serum is useless because it may give misleading reactions. Sterile serum may be kept for months in the cold without much loss of potency. It is best to store serum in small bottles or tubes, each of 1 or 2 c.c., so that there need be no danger of contaminating a large quantity each time a little is to be used. A small amount of chloroform may be added as preservative.

Occasionally rabbit serum is opalescent; such serum is useless because when put in test mixtures one cannot tell for sure whether precipitates are formed or not. In order to avoid opalescence of the serum, it is recommended to let the animal fast for eighteen hours or so before it is bled. In the case of the fowl, only roosters should be used, as the serum of hens often cannot be used on account of its fat content.

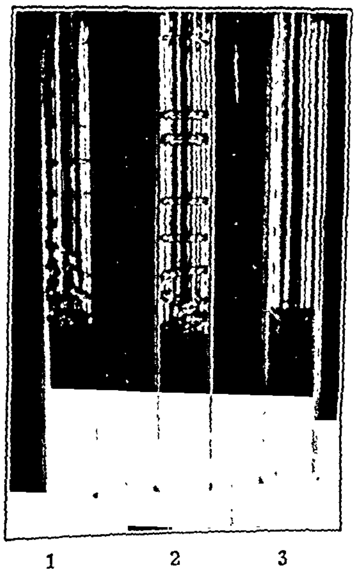

Fig. 1.—Foam Test. Persistence of bubbles about ten minutes after blowing through the fluids in Tube 1, which contained a thousandfold dilution of human blood, and in Tube 2, which contained extract of a blood spot of about the same strength. Collapse of all bubbles in Tube 3, which contained pure salt solution.

TESTS OF PRECIPITIN SERUM

To identify blood or other protein substances it is necessary to use precipitin serum of some degree of potency and of a strictly limited range of action.

Test for Strength.—Various methods have been practiced to determine the strength of a precipitin serum, but I shall mention only the simple method of finding the highest dilution in salt solution of the antigen — the serum or blood of the species used in the injection—with which the precipitin serum forms a precipitate within a few minutes at ordinary room temperature.

Small, perfectly clean and perfectly clear glass tubes are best, the lumen being about 0.5 cm. in diameter. In each of a series of such tubes in a small rack is placed 0.5 c.c. of antigen dilution, the first tube receiving the lowest dilution, the next the next higher, etc. (for example, 1 : 500, 1 : 1,000, 1 :1,500, 1 : 2,000, etc.); there is now introduced by means of a capillary pipet 0.1 c.c. of antiserum at the bottom of each tube, special care being taken to get a precise line of contact between the two fluids. The antiserum also can be run in slowly at the side of the tube; being heavier than the diluted antigen it will go to the bottom of the tube, but the line of contact will not be quite so sharp as when it is introduced at the bottom with a pipet. The tubes, which are kept at room temperature, are now watched for the formation of a grayish-white precipitate at the plane of contact between the fluids.

If a precipitate forms almost at once in the antigen dilution of 1 : 1,000, the antiserum is strong enough to be used for blood tests for forensic purposes. An antiserum that forms a precipitate almost at once in thousandfold dilution of the antigen usually gives reactions in much higher dilutions—1 : 20,000 or higher after a longer time, say twenty minutes. The strength or titer of antiserum may be designated by the dilution of antigen with which it forms a definite precipitate within a given time, at room temperature. For instance, if an antihuman serum gives a precipitate within twenty minutes in a dilution of human serum or blood of 1 : 20,000, its strength or titer may be said to be 1 : 20,000 at twenty minutes.

The precipitin reaction is observed best by holding the tubes near a black, flat object (book cover, ruler) held directly in the path of the light; the precipitate, at first composed of fine particles, and sharply defined, may become more flocculent and sink to the bottom.

To make tests with dilutions of the whole blood, the corpuscles are laked by means of water; the normal salt content is restored by adding the required amount of 1.8 per cent. salt solution (double the strength of physiologic sodium chlorid solution), and further dilutions are made with salt solution of the usual strength. When fowl antiserum is used, the salt content of all dilutions should be 1.8 per cent., as then there is less danger of nonspecific reactions.[4] When fowl astiserum is taken out of the ice box it should be left at the room temperature for an hour or two before it is used.

In place of the contact or ring method, some observers simply mix the antiserum with the antigen;

---

[3] Hektoen, Ludvig: On the Production of Precipitins, Jour. Infect. Dis., 1914, **14**, 403.

[4] Hektoen, Ludvig: The Production of Precipitins by the Fowl, Jour. Infect. Dis., to be published.

a positive reaction now appears in the form of a diffuse cloudiness of the whole mixture. This method is not as precise and sensitive as the contact method, and is not recommended for practical blood tests.

Tests for Specificity.—On account of the relationships of species, almost every strong precipitin serum may form precipitates with proteins, at least in low dilutions, of species related to that species, the blood proteins of which were used for the production of the serum. Indeed, any strong antimammalian serum may react in low dilutions — 1:10 or so — of mammalian serums generally. This is the mammalian reaction of Nuttall.[5] In the case of kindred species, the precipitin affinities often are more marked; for instance, an antigoat serum may react in high dilutions of sheep and beef as well as of goat serum or blood. Further examples of closely related groups are the horse, ass and mule; the dog, wolf and fox; the domestic fowl, turkey, goose, duck and pigeon; the hare and the rabbit, each with more or less pronounced common precipitin reactions. Man and monkey, from the highest down, constitute another group with special precipitin interreactions between the members. How it nevertheless may be possible by the precipitin test to identify the blood of the individual species is discussed later. As each antiserum may vary in the number and strength of its group and other precipitins, and as it must be known to be free from nonspecific reactions before it is used, it is necessary, besides fixing its potency, to determine the exact range of its action. The test for specificity is carried out in the same manner in general as the test for potency; that is to say, tubes are prepared in the same way with dilutions of as many other serums or bloods beside that used in the production of the serum as seem necessary to afford a thorough test, certainly not less than two, the antiserum added as before, and the results noted. At the same time the antiserum is tested with salt solution only to determine whether any precipitate then forms.

A usable antiserum must be perfectly clear; it must have a certain minimum specific precipitin strength, and it must not give any *misleading* nonspecific reactions.

TABLE 1.—SPECIFICNESS OF PRECIPITIN IN SERUM OF RABBIT INJECTED WITH HUMAN BLOOD

Blood	Highest Dilution Giving Precipitate with Antihuman Serum after Twenty Minutes at Room Temperature
Fish	1:10
Chicken	1:10
Rabbit	0
Guinea-pig	1:10
Rat	1:10
Cat	1:10
Dog	1:10
Swine	1:10
Sheep	1:10
Beef	1:10
Horse	1:10
Goat	1.10
Monkey (Macacus rhesus)	1:100
Human	1:5,000

To illustrate: If an antihuman serum is perfectly clear; if it forms a precipitate practically at once in a 1:1,000 or higher dilution of human blood or serum; and if with that of any other species, then in very low dilutions only, say from 1:10 to 1:100, and much more slowly, save possibly in the case of the monkey (group reaction): and if it does not form any precipitate with salt solution, then it may be used for tests for human blood for forensic purposes (Table 1).

PREPARATION OF MATERIAL FOR PRECIPITIN TEST

Materials submitted for blood tests usually are stains and spots on any of the great variety of objects on which blood may fall or be smeared (Table 2). The first question to decide is whether the suspicious spots and stains consist of blood, and for this purpose well known chemical, microscopic and spectroscopic methods are available which need not be described now.[6] It is necessary to determine whether spots and stains are made by blood, not only because blood may be simulated by paint, fruit juices and in other ways, but also because spots and stains made by protein materials other than blood may react in the same way as blood to the precipitin test. For instance, antihuman serum alone will not distinguish spots by human blood from spots by other human protein-containing material such as albuminous urine, seminal fluid, purulent sputum, exudates and transudates. All the antihuman serum can tell us is that the spots are made by human proteins, and whether they are made by blood must be determined by the general tests for blood.

TABLE 2.—PRECIPITIN TESTS FOR BLOOD

Material	Kind of Blood Present	Remarks
Blood on hat, coat, vest, shirts and trousers	Human	The accused claimed the spots were caused partly by fish, partly by calf blood
Blood on blade and inside handle of knife	Human	
Blood on miner's shirt..	Human	In this case, efforts had been made to wash away the blood, but deep in the texture of the shirt the threads were still incrusted with blood
Blood on handle of pickax	Human	
Crust of blood on ax....	Human	Ax found in ruins of house burned down after triple murder
Blood on dollar bill.....	Human	
Blood on coat and trousers	Human	
Blood on bedclothes.....	Human	
Blood on old newspaper	Rabbit	Antirabbit chicken serum used
Smears of blood on neck of bottle	Human	
Blood on shirt	Human	
Blood on shavings......	Human	
Blood on hair, wall paper, floor	Human	
Blood on shoestring.....	Human	
Blood on trousers......	Not human	
Blood on paper.........	Human	
Blood on shoes.........	Rabbit	Antirabbit chicken serum used

All glassware and other articles used in the precipitin test must be absolutely clean and sterile. It is best in all final tests to use tubes that are practically new, because tubes that have been boiled and sterilized many times may be no longer clear. A good supply of fresh, sterile pipets should be on hand.

Salt solution (0.9 per cent.) is the best general solvent for extracting proteins from material to be tested. If practicable, crusted material may be scraped off, ground up carefully and mixed with a small quantity of salt solution; or it may be necessary to place small pieces of cloth, paper or other substances, including some or all of a suspected spot, directly into the solution. Whenever possible, extracts should be made also of unspotted parts of the substratum for purposes of control tests.

How long to continue the extraction depends on the quantity and solubility of the protein in question; if it is to be kept up for more than an hour or two, it is better to put the mixture in the ice box and to add a little chloroform to restrain the growth of bacteria. The passage of protein into solution is indicated if bubbles made by blowing through the fluid with a pipet tend to persist (foam test); also if cloudiness develops on application of the nitric acid heat test. As only a dilute solution — 1:1,000 — is wanted for the precipitin test, extracts of blood usually have to be diluted with salt solution. When the nitric acid heat test barely causes a faint opalescence in a blood dilution, its strength is regarded as about 1:1,000. Comparative foam tests, known blood dilutions being used as the standard, also help to fix the strength of an extract (Fig. 1). A 1:1,000 dilution of blood is practically colorless by transmitted light. The extracts should be clear as water; turbid extracts must be cleared by filtration or centrifugation. The reaction must be neither strongly acid nor alkaline to litmus; for neutralization, 0.1 per cent. sodium hydroxid or hydrochloric acid solution should be used; dilutions of blood at 1:1,000 rarely need to have the reaction corrected, but extracts of wood, bark and leather may contain acids that cause cloudiness in rabbit serum.

[6] Wood, E. S.: Medicolegal Examination of Blood and Blood Stains: A Text Book of Legal Medicine and Toxicology, edited by Frederick Peterson and Walter S. Haines, 1904, 2, 722.

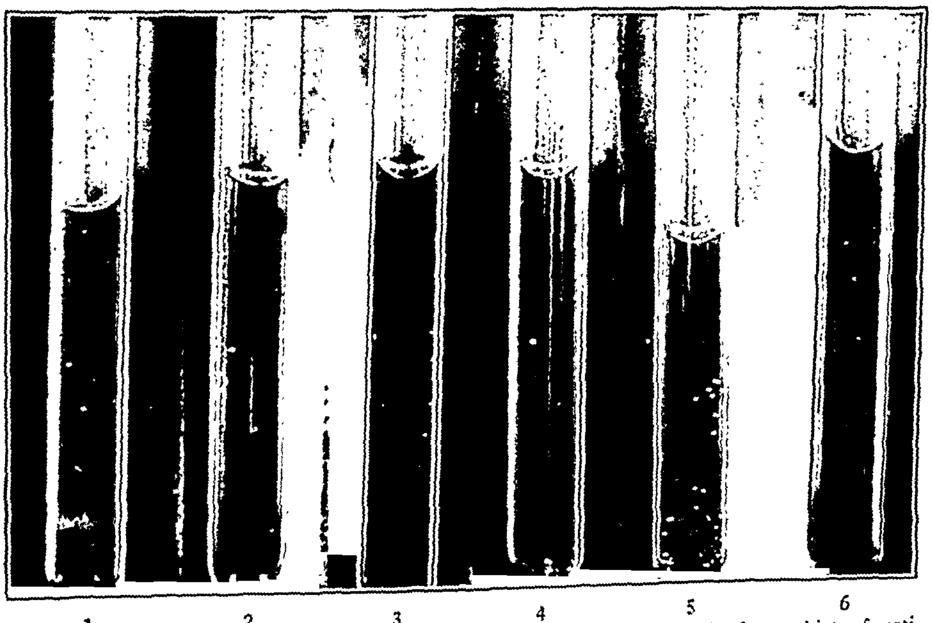

Fig. 2.—Precipitin Test for *Human Blood*: Tube 1, extract of blood on shirt of estimated dilution 1:1,000 + antihuman rabbit serum; Tube 2, extract of blood on shirt of estimated dilution 1:1,000 + normal rabbit serum; Tube 3, extract of bloodless part of shirt + antihuman rabbit serum; Tube 4, salt solution + antihuman rabbit serum; Tube 5, dilution of human blood 1:1,000 + antihuman rabbit serum; Tube 6, dilution of sheep blood 1:1,000 + antihuman rabbit serum. The precipitates in Tubes 1 and 5 formed almost at once; photograph was taken from five to eight minutes after introduction of the antiserum.

Stains that do not extract well with salt solution may give better results if treated with a 1 per cent. solution of potassium cyanid; the alkalinity should be corrected with tartaric acid (Sutherland).

In case of cloth with suspicious stains that yield no information on being scraped or soaked, it is a good plan to cut out small pieces from the stains and tease them apart. The single threads running in the depth of the stained part may be found incrusted with blood, that is, covered with small crusts which contain red blood corpuscles or in which the blood is demonstrable in other ways. Even when the cloth has been washed recently, incrustations may be found in the depth, especially, of course, if the cloth is of a heavier sort.

THE ACTUAL TEST AND CONTROLS

The precipitin test requires a number of careful controls to guard against error; the antiserum must be tested with salt solution, with the blood against which it is known to act, and with other bloods in order to make sure that it gives a specific reaction only. Samples of various kinds of blood should be kept on hand for control tests. For this purpose blood may be dried in drops on filter paper or linen, each drop being made by a definite quantity (0.1 or 0.05 c.c.); or the blood may be kept in the cold, diluted as described, say 1:100 in salt solution. As the reactive power of blood kept in solution is said to weaken gradually, too long intervals must be avoided before new solutions are prepared. To avoid still other chances of error, the extract of the unknown blood must be tested with normal rabbit serum or, if fowl antiserum is used, with normal fowl serum, and extract of blood-free parts of the substratum on which the unknown blood was situated is to be tested with antiserum. These precautions have to be observed in connection with every forensic precipitin test — *nothing may be taken for granted*. Assuming now that spots on a shirt that have been shown to consist of blood are to be tested for human blood, the precipitin test may be conducted in accord with the scheme presented in Table 3, it being understood that the quantity of extract or control solution in each tube is 0.5 c.c. and of antihuman rabbit serum or normal rabbit serum, 0.1 c.c. These quantities may be reduced if desired in order to save material; indeed, the test may be made in capillary tubes if necessary.

If a typical precipitate (Fig. 2) develops within a minute or two in Tubes 1 and 5 while no precipitate forms in any of the other tubes after standing for twenty minutes, all at the room temperature, *then the conclusion is warranted that the blood on the shirt is human blood*. Some observers would add, provided monkey blood can be excluded (see final section).

Having obtained a positive reaction with the extract under the aforesaid conditions, I always determine next the highest approximate dilution of the extract that reacts with the antiserum after twenty minutes at room temperature, thus still further verifying the specificness of the reaction.

Usually the only questions asked are whether certain spots and stains are due to blood, and if so, to human blood; but sometimes it becomes necessary to determine if possible the exact species of blood that is not human. The scheme for human blood is applicable

TABLE 3.—SCHEME FOR PRECIPITIN TEST (FIG. 2)

Tubes	
1	Extract of blood on shirt + antiserum
2	Extract of blood on shirt + normal serum (estimated dilution of blood in Tubes 1 and 2, 1:1,000)
3	Extract of bloodless part of shirt + antiserum
4	Salt solution + antiserum
5	Human blood or serum 1:1,000 + antiserum
6	Blood or serum other than human 1:1,000 + antiserum
7, 8, etc.	Same as Tube 6, but with different bloods.

in general with, of course, such changes as to antiserums and controls as are indicated in the given case from the facts at hand. If the blood corpuscles are preserved, it may be possible to determine from the absence or presence of nuclei whether or not one is dealing with mammalian blood. Often tests with various antiserums may be made before a positive reaction occurs, and it must not be forgotten that absence of reaction may be due not only to failure to hit on the right antiserum, but also to changes in the unknown blood whereby it has lost its power to react.

The question whether more than just one kind of blood is present in material to be examined may be raised. It has been found that in mixtures each kind of blood present can be identified by the precipitin test; in such cases, antiserums of as high potency as possible should be used, as it may be difficult otherwise to detect proteins present in small amounts.

FACTORS THAT MAY INTERFERE WITH THE REACTION

The power of blood to react with precipitin may be reduced or completely destroyed by alcohol, by formaldehyd, cresol and other germicides, by acids and alkalis and other chemicals, by peptic digestion, by decomposition, and by heat. Badly decomposed blood may react, but it is hard to get clear extracts. Fluid blood is said to lose power to react on being heated at from 60 to 90 C., but dried blood may resist heating at 150 C. Rust also is said to change blood so that it reacts less readily. Blood in spots from 15 to 60 years old has been identified successfully, but certain statements that materials from thousand year old mummies may give the precipitin reaction have been contradicted.

Dried blood resists harmful influences much better than fluid, and if blood found in the fluid state is to be kept for tests later on, it is better to dry samples on filter paper than to keep it in fluid form in which it may decompose. Under no circumstances should blood or bloody material for the precipitin test be put in alcohol, because alcohol causes changes that interfere with the test.

OTHER USES OF THE PRECIPITIN TEST

The precipitin test may be of value also in the identification of bone and other tissue the origin of which is in doubt, as perhaps only fragments and scraps are at hand. When dissolved, the proteins in and of the tissues give the same general response to the precipitin test as the proteins of the blood of the species concerned. The only exception to this rule is furnished by the crystalline lens, which is unique, as it reacts only to serum produced by injections of lens substance, and that without regard to species. Bone should be reduced to powder, washed thoroughly with ether or benzin to remove the fat, dried, and then extracted with salt solution. Tissue of other nature may be treated according to the same principles. Such extracts are tested in the same general way as blood extracts.

Putting white of egg in urine to simulate albuminuria, and spattering nonhuman blood on clothing and bedding to feign spitting of blood, have been detected by the precipitin test. The test has been used extensively in certain European countries to detect adulterations of meat products and other foods, as flour and honey; it has been found of value, too, in the administration of game laws.[7] Finally, it may be mentioned that under certain circumstances the precipitin test may prove of service in the study of occult blood in the feces; but these are all matters that may not be discussed at this time.

SPECIAL METHODS FOR THE DIFFERENTIATION OF BLOOD OF CLOSELY RELATED ANIMALS

Examples of related animals with more or less common precipitin reactions have been given. In thousandfold dilution a blood may react so much more promptly with its own antiserum than even lower dilutions of related blood that commonly no difficulty arises, provided the limits as to dilution and time are followed exactly as prescribed and the necessary controls included in the test. Nuttall's experiments, to which I have referred, were made according to a totally different plan, the blood dilution being several times lower than 1 : 1,000, and the mixtures allowed to stand for several hours. To repeat: A reaction between an antihuman serum and a thousandfold blood dilution is diagnostic of human blood, provided it becomes evident within a few moments and that within twenty minutes at room temperature no reaction occurs between the same antiserum and like dilutions of the blood selected for the control tests Sutherland[8] made a special study of stains by the blood of many varieties of monkeys, his tests being made with the dilutions and time limit just set forth, and in no instance, not even in the case of the orang, did he get a positive result with antihuman serum; consequently, special methods do not seem necessary to distinguish human from monkey blood. These observations should be repeated so that if possible final standards may be fixed. In this country the question whether ape or monkey blood may be present is not likely to arise, because the circumstances, as a rule, preclude all chance that such blood can be present.

That differentiation may be difficult is illustrated by the ruminant group. Antibeef serum, for instance, may react in high dilution of beef, sheep, goat and perhaps also other ruminant blood. Indeed, any antiruminant serum may react with any ruminant blood in considerable dilution, although not with equal promptness in all cases. Several expedients have been recommended in this and similar cases:

1. *Specific Absorption* (Weichardt).—This is based on the principle that by mixing, let us say, antibeef serum with goat serum and then removing the resulting precipitate, the special antigoat precipitin will be removed. The method is circumstantial and is not regarded as of practical value.

2. *Cross Immunization* (Uhlenhuth).—This consists in obtaining precipitin serum from one animal for the proteins of a related animal. Injecting certain Old World monkeys with human serum, Uhlenhuth obtained antihuman precipitins, but this result seems to be quite exceptional, as neither Sutherland[8] nor Berkeley[9] were able to confirm it. Uhlenhuth was able to demonstrate hare blood on a cane by means of antihare precipitins developed in the rabbit, antihare fowl serum reacting equally well with hare and rabbit blood; he also found that the fowl produces antipigeon precipitin and the pigeon antifowl, but cross immunization failed in the case of the horse-ass, and goat-sheep.

[9] Berkeley: The Impossibility of Differentiation Between Monkey Blood and Human Blood by Means of Antisera Derived from Monkeys, Univ. of California Publications in Pathology, 1913, 2, 105.

3. *Dilution of the Antiserum and of the Suspected Blood.*—Dilution of an antiserum may so weaken certain confusing group precipitins as to cause their practical elimination and still leave the main precipitins strong enough to give a specifically diagnostic reaction under the conditions prescribed for forensic practice. For diluent, Sutherland and Mitra[10] recommend normal serum of the same kind as the antiserum.

It is, of course, in the low blood dilutions that antiserums of high potency give the most marked group reactions. As the dilutions of the bloods of a group are increased, the reaction narrows down more and more, and in high dilutions there may be no question as to its specificness. Hence, determination of the highest dilution in which a suspected blood reacts with a given antiserum, if properly controlled, may solve the problem.

4. *Special Study of Rapidity and Measure of Reaction.*—Hamburger[11] recommends that in the case of a stain that reacts with antiruminant serum, for instance, separate parts of the extract be tested with antigoat, antisheep and antibovine serum in the usual way, and the results carefully noted. The antiserum that gives the most rapid and profuse precipitate supplies the clue.

Systematic detailed studies should be made on the blood of closely related animals in order to determine more fully to what extent differentiation can be made by these and possibly other methods.

Suggestions to the contrary[12] notwithstanding, it is not possible to distinguish between different human races, and far less between individuals, by means of the precipitin test.

TRAUMATIC CEREBRAL EDEMA CAUSING LATE SIGNS OF FOCAL CORTICAL IRRITATION

REPORT OF CASE

GONZALO E. ESPEJO, M.D.
Assistant in Neurologic Surgery, New York Polyclinic Medical School and Hospital
NEW YORK

History.—A boy, aged 7 years, was brought to the hospital by ambulance, after being struck and rendered unconscious by an automobile while playing in a snow pile, in the evening of Dec. 23, 1917; he was admitted to the service of Prof. William Sharpe.

From the meager history of the accident that could be obtained, the child was unconscious when picked up, frothing at the mouth, and bleeding from the right ear and the nostrils.

Examination.—At the hospital, within an hour after the accident, he was drowsy; although his eyes were open and he would answer rationally when spoken to, he was lying quietly and unconcerned, occasionally moving the extremities. There was a small amount of dry clotted blood in both nares and also in the right external auditory meatus. A hematoma, the size of a half dollar, with a slight superficial laceration in the center, was present over the right parietal eminence without evidence of underlying bone depression. The pupils were moderately dilated and reacted equally to light. There were no evident paralyses of either side of the face or the extremities. The abdominal reflexes were abolished. Patellar reflexes were moderately exaggerated on both sides. No Babinski or Oppenheim reflexes could be elicited. No impairment of sensation could be ascertained. An ophthalmoscopic examination of the eye grounds revealed a moderate dilatation of the retinal vessels without any apparent blurring of the details of the optic disks or their margins. A spinal puncture revealed clear cerebrospinal fluid, the spinal mercurial manometer registering a pressure of 10 mm. (the normal is from 8 to 10); the rectal temperature was 97.8; the pulse, 84; respirations, 20. The patient was then removed to the ward, and the routine expectant palliative treatment instituted.

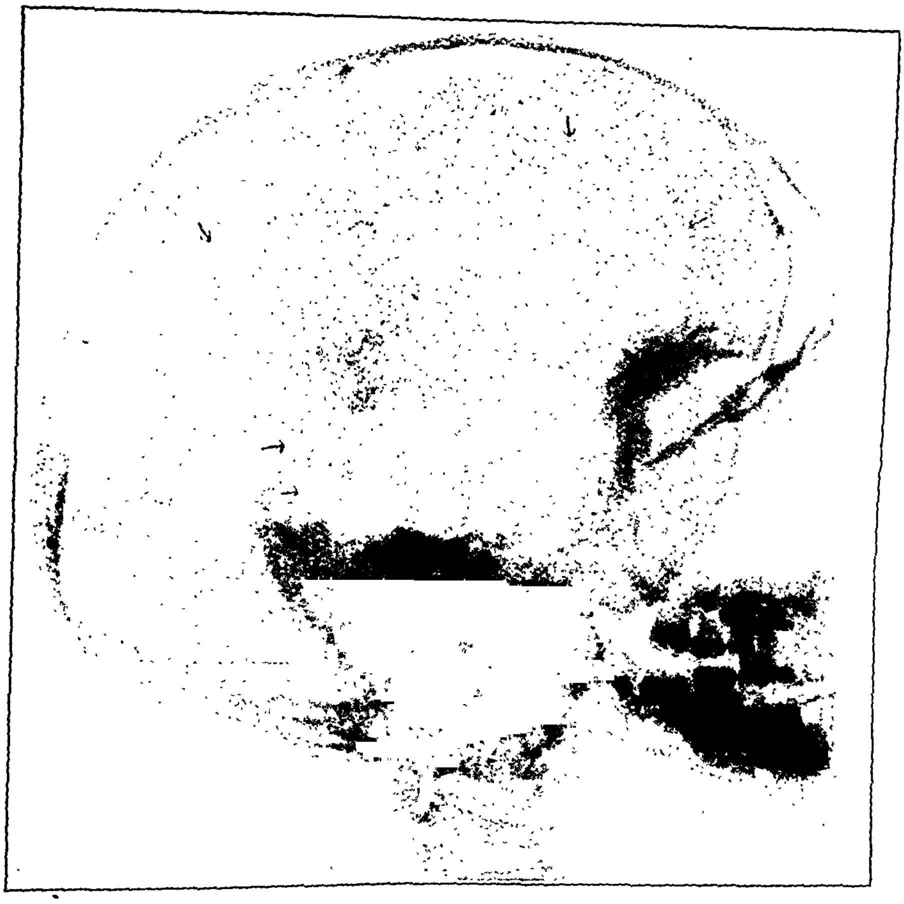

Fig. 1.—Extensive linear fractures of the right parietal and frontal bones. There is also a linear fracture radiating through the squamous portion of the right temporal into the petrous portion.

Bedside Notes.—December 24, the patient had slept quietly last night, except once when he appeared restless and tried to get out of bed, but soon fell asleep again. The temperature remained at 100 until 5 p. m.; the pulse, 96; respirations, 24. The temperature gradually ascended to 104.6 during the next twenty-four hours. Throughout the day, the patient could be aroused and would answer when called by name, but went to sleep again. He refused nourishment.

Ophthalmoscopic examination by Dr. J. A. Kearney revealed slight general edematous changes blurring both disks equally.

Roentgen examination by Dr. G. W. Welton revealed extensive linear fractures of the right parietal and frontal bones. There was also a linear fracture radiating through the squamous portion of the right temporal into the petrous portion.

December 25, the patient had had a fairly good night with occasional periods of restlessness, but at times he was awake and quiet; he seemed rational. The temperature in the afternoon was 104.6; the pulse, 142; respirations, 30. He was very restless all day.

December 26, the patient had had a very good night. The temperature was 102; the pulse, 104; respirations, 24. He took nourishment very well. He complained of his neck being sore; he was very quiet all day; he called for his mother; he liked the ice bag at the neck. The patellar reflexes were sluggish. The fundi oculi showed no added haziness of the optic disks.

December 27, the patient had had a very comfortable night; he took nourishment as well as on the preceding day; he took a cup of milk in his hand and drank it; once he sat up in bed and played with the electric light; he was rational, and answered all questions. The temperature was 99; the pulse, 96; respirations, 20.

December 28, he had slept well all night. He took nourishment well. He had an orange in the morning, and enjoyed it. He complained of frontal headache in the afternoon. The temperature, pulse and respirations were the same as the day before.

December 29, he had had a very good night. At 7:30 a. m. he had milk with bread; he enjoyed a bath; he was very quiet afterward. The temperature was 99; the pulse, 84; respirations, 20. At 8:30 a. m., one hour later, the patient was reported as having severe spasmodic contractions of the left side of the face, with marked dyspnea and cyanosis. The temperature was 99; the pulse was 144; the respirations were 30.

An examination disclosed besides clonic spasmodic contractions of the left half of face and neck coming on in quick succession, and lasting several minutes, a complete flaccid paralysis of the left arm and leg, fixed eyes wide open, dilated pupils, and complete unconsciousness. It was thought advisable, therefore, to perform an exploratory decompression and drainage over the right cerebral cortex.

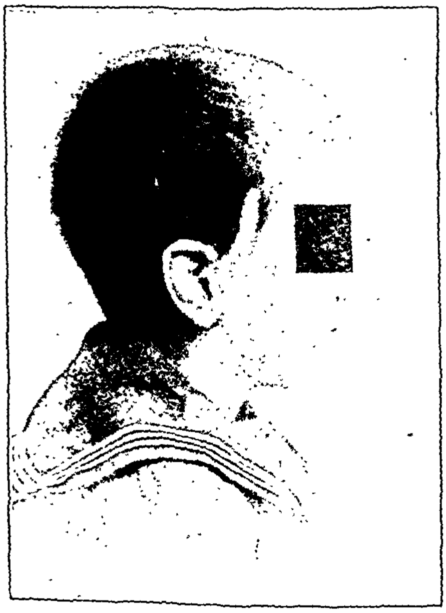

Fig. 2.—Scar of subtemporal decompression.

Operation and Results.—A right subtemporal decompression and drainage were performed. A vertical incision 3½ inches long was made from the temporal attachment at the parietal crest to the root of the zygoma, one-half inch anterior to the external auditory meatus. The temporal fascia was incised and the muscle retracted in the direction of its fibers. The temporal bone revealed no line of fracture. The periosteum was removed and the cranial cavity opened with the Doyen perforator and burr, after which the opening was enlarged with a rongeur. The dura appeared under normal tension, dusky-red, nontransparent, thickened, and difficult to incise. Only a few drops of cerebrospinal fluid escaped through a nick in the dura, showing that there was no general increase in the intracranial pressure, but rather a focalized cortical edema, possibly due to the cortical contusion.

Radiating incisions were made through the dura toward the edges of the bone gap, no subdural clots being encountered. The cortex was edematous and grayish, the cortical vessels were dilated and tortuous. The dura was left open, and two rubber tissue drains were inserted under each angle of the incision and over the cortex. The wound was closed with catgut and fine silk suture.

The patient had slight twitchings of the left side of face, four hours after operation, which soon subsided. The patient became wide awake and conscious. He had full control of the left arm and leg. The reflexes were apparently normal. The temperature, pulse and respirations remained normal throughout convalescence. The patient was discharged well, on the twelfth day after operation.

The child has made weekly visits to the clinic for the past two months. He appears normal in every way, and has gained several pounds in weight.

COMMENT

This case illustrates two important points in the care of patients having brain injuries with or without a cranial fracture. First, as to the diagnosis of the extent of brain injury at the time of the accident, and second, as to the mode of treatment to be pursued after a diagnosis has been reached.

From the foregoing report, it is obvious that the late signs of paralysis and convulsions coming on after a traumatism of the head could have been produced by the same causes, irrespective of the presence of fracture. Therefore, in any head injury, with temporary unconsciousness, even if the patient, after recovering from the initial shock, progresses toward a recovery, the surgeon should be most vigilant lest such signs should develop at a later date, which would warrant immediate surgical measures; the prognosis, in the meantime, is always uncertain. All these injuries should be considered as serious, whether or not the skull is fractured, because considerable damage probably may have been produced to the brain substance or to its membranes. Also, the more remote signs of inflammation of the cerebral tissues should be watched for. Many patients who recover from the immediate effects of an injury to the brain may later develop epilepsy, a changed personality and even dementia itself, whereas in other cases, there is complaint for a long time of headaches, and depressed and excitable conditions.

The latter post-traumatic complications may in a large measure be obviated by the more precise methods of diagnosis now at our command, such as are the measurement of the intracranial pressure at lumbar puncture, and the ophthalmoscopic examination of the fundi of the eyes.

In this particular patient we can infer almost at a glance the probable occurrence of a fracture, most likely including the petrous portion of the right temporal bone, as indicated by the clotted blood at the auditory meatus; also, the possibility of a fracture of the anterior fossa from the presence of the dry blood in the nostrils, although both of these conditions may have been due to local bleeding in these regions. The history leads one to the conclusion that the condition we had to deal with was fracture of the skull, as the patient was said to have been picked up in an unconscious condition, frothing at the mouth, and bleeding from the right ear and nostrils.

The physical examination revealed that the patient had recovered within an hour from the initial unconsciousness, leaving him in a quiet, somewhat drowsy condition, with exaggeration of the patellar reflexes, moderate dilatation of the pupils, slightly subnormal temperature, and normal pulse and respirations. These signs pointed to the fact that the patient had at least cerebral concussion, possibly a cerebral contusion, and a possible fracture of the skull, of which we were not sure.

We attach no great importance to the small hematoma in the right parietal eminence, although we are inclined to believe that the trauma was received at this point, and an underlying fracture may have occurred; it would thus have involved the vault, radiating then to the base, as it has been shown that from 60 to 70 per cent. of fractures of the vault radiate to the base, and conversely.

Such inferences from the history and the physical signs must be substantiated by more accurate methods of procedure, in order to decide whether there are present definite signs of increased intracranial pressure for which an operation should be immediately performed after the patient has reacted from the primary shock, or whether he should be treated expectantly with rest, quiet, low diet, purges, ice helmet, and sedatives for restlessness and delirium, and carefully observed for subsequent signs of localized cortical irritation or general signs of cerebral compression.

The use of the roentgen ray is an important adjunct in revealing the presence of fracture, but its importance is only secondary to the estimation of the degree of intracranial pressure, whether this is due to hemorrhage or to primary edema.

It is necessary, then, in all patients having head traumatism, in whom there has been more or less disturbance of consciousness from a temporary confusion and giddiness to a partial or complete unconsciousness, that we arrive at an immediate decision as to the amount of intracranial pressure, irrespective of the presence of fracture, by means of the proper use of the spinal mercurial manometer, and by making repeated examinations of the eye grounds. This has been the course of procedure followed in more than 500 cases of brain injuries on the service of Dr. William Sharpe, at the Polyclinic Hospital, with a mortality of only 19 per cent., excluding those patients admitted in a moribund condition, in whose cases no operation was advisable, and in whom the brain injury was merely an incident in the general condition. Only those patients are operated on who have recovered from shock, with a pulse rate below 120, the spinal manometer registering 15 mm. of pressure or over, and the ophthalmoscope revealing partial or complete obscuration of the ocular disks. Less than one third (31 per cent.) of these patients having brain injuries, with or without a fracture of the skull, have shown the varying degrees of high intracranial pressure, and only those have been operated on, with the results noted above.

The patient under discussion showed a pressure of 10 mm. of mercury, which is within normal limits. The cerebrospinal fluid was clear, indicating that no subdural bleeding had occurred. The dilatation of the retinal vessels, without any marked blurring of the optic disks, represents the usual ophthalmoscopic findings, in the majority of so-called cerebral concussion cases, with or without a fracture of the skull, within the first six hours after the accident. Later on, as the patient recovers from the shock, and the intracranial pressure increases, the optic disks undergo a general haziness. If the pressure is still higher, there will be an added obscuration, first of the nasal, subsequently of the temporal halves of the disks and their margins.

On the second and third days after this patient was admitted to the hospital, he presented the usual clinical signs of a case of concussion, as indicated by the occasional period of restlessness, headache, pain in the neck, drowsiness, and the initial rise in temperature. All these signs disappeared within the next forty-eight hours, and the patient was well on his way to recovery. Repeated fundal examinations revealed only a moderate degree of haziness of the disks, but not enough to warrant a lumbar puncture, as the other concomitant signs were gradually disappearing.

Thus, it may be seen that this patient did not show a definite increase in the intracranial pressure, but rather a local edema of the contused brain tissue, causing an irritation extending to the prerolandic area controlling the side of the body that was affected. A similar condition may be produced in cases of brain injury, complicated by a secondary infection, causing a meningitis or a meningo-encephalitis, whether of the acute type or the chronic form with the formation of a definite abscess — cortical or subcortical. Here also, a cranial decompression and drainage is the proper course of procedure.

CONCLUSION

In view of the signs and symptoms that were present in this patient, and their subsequent development requiring an immediate operation, it makes it imperative that patients, in whom, from the history or from the signs present on examination, a brain injury is suspected to have occurred, should have a lumbar puncture performed and repeated ophthalmoscopic examinations of the ocular disks.

Should there be no marked increase in the intracranial pressure nor localized signs of cortical impairment, then the expectant palliative treatment should be instituted, and if in shock, naturally no operation should be performed until the patient has reacted from it.

The prognosis in this class of patients is regarded as most uncertain, and they must always be carefully watched and examined for fear of immediate and future complications. But when these patients are watched carefully and operated on promptly when the symptoms justify operative intervention, the prognosis, as shown in this patient, is excellent.

Butter Substitutes.—As margarins are popularly supposed merely to differ from one another in price and palatability, any substitute fats placed on the market in bulk will command a ready sale. A word of caution on this point seems desirable. It is known that butter is particularly rich in one of the "accessory substances" necessary to healthy metabolism. Drummond and Halliburton in a recent note (Proc. Physiol. Soc., Jour. Physiol, 1917, **51,** 8) have called attention to the fact that this substance is not found indifferently in all margarins. According to them the oleo-oil margarins, which have as a basal fat an oleo-oil prepared from beef fat, can fully replace butter in the dietary. Vegetable oil margarins, on the other hand, which are usually prepared from coconuts, peanuts, etc., are by no means equal to butter and the oleomargarins in nutritive value. Apparently the fat-soluble accessory substance is present in the coconut fibers and absent from the expressed oil. Hence some of the vegetarian suets and lard substances, which are often deodorized coconut oil, or hydrogenated cottonseed oil preparations, are unsatisfactory.—*British Medical Journal.*

ARE ALL THE TUBERCLE BACILLI FOUND IN THE SPUTUM VIRULENT?*

H. J. CORPER, M.D.
CHICAGO

On account of the lack of conclusive available data on the virulence of tubercle bacilli in the sputum of consumptives, and the tremendous importance of this information for the institution of hygienic measures in preventing and eradicating the disease, it was deemed advisable to investigate this problem. The earlier literature on this subject deals with it pro and con, but is not clear cut and decisive, lacking substantiating experiments. From this literature, however, there are several conspicuous considerations which must be kept in view in performing experiments to determine the virulence of tubercle bacilli. Fraenkel and Baumann[1] found guinea-pigs alone (not rabbits, rats or mice) to be available for revealing differences in pathogenic properties of tubercle bacilli. Marmorek[2] calls attention to the fact that as a criterion of the infectious power of tubercle bacilli it is necessary to note the distribution of the anatomic lesions, and only in a very insignificant manner consider the duration of life.

This investigation was begun, therefore, to determine the range of virulence of tubercle bacilli isolated from the sputum in open cases of pulmonary tuberculosis. Its purpose was not to determine the smallest number of individual tubercle bacilli necessary for causing infection, with a view to producing immunity with them, as was the case in Webb, Gilbert and Gregg's work. On account of the elaborate apparatus and consumption of time necessary to determine the virulence of a large series of cultures by the Barber method, it was deemed satisfactory to use the dilution method, after weighing the amounts of bacilli used, and to count the bacilli by staining them after carefully making the various dilutions. This method had the added advantage of protecting the bacilli from exposure to light, which can not be avoided by the Barber method and which may have an influence on the virulence of the bacilli. To secure absolutely accurate scientific data on the virulence of tubercle bacilli contained in any excreta or body fluids, it would, of course, be advantageous to use the bacilli directly from the material without previous culture, since it is conceivable that there may be bacilli of low virulence or dead bacilli in the material under investigation, which are not taken into consideration because they do not grow as well as the more hardy and virulent types.

There are a number of arbitrary points that must be considered when we speak of virulence, especially of an organism of the type of the tubercle bacillus. It is, of course, known that this term is merely relative. An organism may be highly virulent for one type of animal and yet be avirulent for another. Thus, for example, the human tubercle bacillus is avirulent for the rabbit. This means within reasonable doses (0.1 mg.) and within reasonable time. The guinea-pig was therefore chosen as a suitable experimental animal for determining the virulence of the human tubercle bacilli dealt with in this investigation. An organism avirulent for this highly susceptible animal would certainly not be very pathogenic for man. The rabbit was used merely to determine the type of bacillus, whether human or bovine. Another important fact which should be pointed out at this time is that emphasized by Cocke,[3] that the infection in the human being is due to repeated or prolonged, rather than a single, exposure.

It is also advisable to call attention to the fact, brought out recently by Krause,[4] that death in tuberculosis is due generally to accident. This is especially significant in ruling out duration of life as a factor in determining the virulence of the tubercle bacillus.

RESULTS OF VIRULENCE TESTS

The tubercle bacilli used for the virulence tests were directly cultivated from the sputum by Petroff's method[5] and were usually from one to two months old. No appreciable difference was noted in the virulence of the bacilli taken from the same culture at from one to three months. For the tests, an emulsion was made equivalent to 1 mg. of the moist culture in 1 c.c. of physiologic sodium chlorid solution, so that on examination the bacilli were found at most only in lumps of from two to ten. The emulsion was then diluted with physiologic sodium chlorid solution until 1 c.c. contained 0.1 mg., 0.001, 0.000,0001 and 0.000,000,01 mg. These amounts were then injected into four male guinea-pigs, all of the same size and weighing from 500 to 600 gm. At the end of two months after infection, the guinea-pigs were examined for anatomic involvement and graded from — to ++++, depending on the extent of the involvement. The number of bacilli found per milligram of moist culture was from 5 to 6 billions, so that the 0.000,000,01 mg. dilution contained from fifty to sixty tubercle bacilli.

A total of eighty-two cultures directly isolated from the sputum were thus examined, and all but two of these produced tuberculosis in the guinea-pigs within two months after a subcutaneous injection of 0.000,001 mg. of the moist culture. Of the two negative cultures, one was entirely negative, not even producing systemic tuberculosis in the guinea-pig in 1 mg. dose. Of course this amount produced a local tubercle, as always occurs even with avirulent laboratory strains; but no evidence of disease was ever found beyond the local glands. The other culture produced only a slight tuberculosis in 0.001 mg. amounts. Of the eighty cultures that produced a systemic tuberculosis (beyond the local glands) in 0.000,001 mg., eleven were not examined below this amount, sixty-two produced systemic tuberculosis in 0.000,000,01 mg. amounts within two months, while seven were negative in this amount. Of the sixty-two which produced systemic tuberculosis in 0.000,000,01 mg. amount, thirty-two gave a ± or + involvement of the retroperitoneal glands, and possibly a slight involvement of the spleen; twenty gave a ++ involvement of the retroperitoneal glands, a well marked and definite involvement of the spleen and possibly of the peritracheal glands; eight gave a +++ involvement of the retroperitoneal glands, and spleen markedly, of the peritracheal glands, of th [illegible] ver slightly and the lungs slightly, and two gave a [illegible] +

[5] Petroff, S. A.: Jour. Exper. M

involvement, amounting to an entire massive systemic infection of practically all the important organs. Of the eighty-two cultures examined, eighty were definitely of the human variety, either producing no tuberculosis in the rabbit after the intravenous injection of 0.1 mg., or producing only a miliary tuberculosis of the lungs within two months. One of them was intermediate, causing a tuberculosis of the lungs, kidneys and omentum, but not death, within two months, and the other appeared to be bovine, causing tuberculosis of the lungs, liver and spleen, and death of the rabbit within one month. No relation between the virulence in the rabbit and in guinea-pigs could be noted from the experiments as performed.

The cultures were isolated from fifty-seven far advanced (National Association classification), eighteen moderately advanced, and seven incipient cases. Of the fifty-seven far advanced cases, thirty presented severe constitutional symptoms, and ten of these patients died in the sanatorium within a year; ten presented moderate constitutional symptoms, and one of the patients died within a year, and seventeen presented either slight constitutional symptoms or none at all. Of the eighteen moderately advanced cases, two presented severe symptoms, one of the patients dying within a year, five presented moderate and eleven slight constitutional symptoms or none at all. All seven incipient cases presented only slight constitutional symptoms or none at all. As far as could be observed, there seemed to be no relation between the severity of the disease in man and the virulence of the organism for the guinea-pig. There was just as little relation between the anatomic involvement in man and the virulence for the guinea-pigs.

CONCLUSIONS

The foregoing investigations have revealed that in the majority of open cases of pulmonary tuberculosis, the tubercle bacilli which could be isolated on artificial mediums from the sputum were virulent enough to produce systemic tuberculosis in guinea-pigs, by means of doses as small as 0.000,001 mg.; and that the range of variation of virulence was very small, as was also pointed out by Gilbert and Gregg,[6] who found it to lie between ten and 120 bacilli. If the virulence of the bacilli as cultivated on artificial mediums is a direct expression of their virulence in the sputum, there is only one conclusion to be drawn from the foregoing findings, as viewed from a practical standpoint, and that is, that in open cases of pulmonary tuberculosis the tubercle bacilli discharged by droplet or by expectoration, when still uninfluenced by drying and light, are a danger to mankind, through direct transmission at least. In applying these findings to mankind, there was found in the literature only one reference which would indicate the relation between the number of bacilli of the same culture necessary to infect a guinea-pig and to infect man. These observations were made by Webb and Gilbert,[7] who found that a culture of human tubercle bacilli, sufficiently virulent to infect a guinea-pig when ten bacilli were used, was also capable of infecting a child in practically the same dose. It seems justifiable, therefore, to conclude that the tubercle bacilli found in the sputum of patients in open cases of pulmonary tuberculosis (provided the bacilli capable of artificial cultivation are a true index of those existing in the native sputum) vary only slightly in virulence for guinea-pigs, and are for practical purposes nearly all pathogenic. That is, in 97 per cent. of the cases, they will infect a child, as may be deduced from Webb and Gilbert's observations, in a dose of less than one-millionth milligram. These experiments also seem to lay special emphasis on the examination of the sputum of men in military service or about to enter it.

TREATMENT OF DIABETES FROM THE GENERAL PRACTITIONER'S STANDPOINT

N. W. JANNEY, M.D., Ph.D.
NEW YORK

In spite of the recent important advances made in diabetic treatment by the studies of Allen, Joslin, Mosenthal and others, our profession at large has failed to profit in a corresponding degree. The reasons are not difficult to ascertain. Success in the treatment of diabetes lies in the smooth coordination of clinical experience in the disease with a practical system of diabetic dietetics and accurate chemical laboratory methods. Neither the general practitioner nor, indeed, the general internist can be expected to meet these severe requirements, as both treat too few diabetics at any given time to permit of elaborate dietetic management. The result is that the treatment of diabetes, at present, is carried out successfully by a relatively few physicians who have the help of a specially modified institutional system. However, the management of this difficult disease must of necessity still be largely conducted by the general practitioner and internist. No very definite attempt has been made to adapt the modern treatment to these needs.

This unsatisfactory state of affairs has been impressed on me in teaching physicians at the New York Post-Graduate Medical School. Accordingly, a simplified scheme has been worked out to fill this general need. It has been used sufficiently to demonstrate its utility in the hands of physicians with little previous experience with diabetic patients. My purpose in this article is to describe the principles of this plan together with other points of practical importance to the general practitioner. This plan of treatment, in which fixed dietaries are introduced, is by no means ideal, but is serves a very definite purpose. Whenever possible it should be replaced by more specialized dietetic and laboratory methods.

FALLACIES IN DIABETIC TREATMENT

Correction of poor treatment is a necessary adjunct to the introduction of better treatment. General carelessness may be mentioned first. Diabetes is eminently chronic. Many patients apparently get along well over long periods of time with sugar in the urine. The case is allowed so to continue until irreparable complications or unconquerable acidosis develops. It cannot be too forcibly emphasized that the only danger-free existence for the average diabetic is a sugar-free existence.

Allowing the patients more food than is absolutely necessary is always inadvisable. It must be remembered that both protein and fat, in excess, as well as carbohydrates may cause lowering of the tolerance and eventually glycosuria and acidosis. According to my studies,[1] 50 per cent. or more of protein is converted into glucose in the diabetic organism. By stimulating protein breakdown, fat may lead to increased sugar production. For the same reason the use of special "diabetic foods" containing large amounts of protein is inadvisable, as I have previously pointed out.[2] In spite of various publications to the contrary, the unlimited use of gluten bread as a "good diabetic food" is still recommended by some physicians. Its use is undoubtedly responsible for the death of many diabetics. Gluten breads contain large amounts of protein and frequently carbohydrate, as well.

[7] Webb, B., and Gilbert, G. B.: Immunity in Tuberculosis, The Journal A. M. A., Sept. 26, 1914, pp. 1098-1104.

The "oatmeal cure" is still occasionally used. The virtue of the oatmeal diet seems to be chiefly in the fact that the monotony of such food causes less caloric intake with corresponding improvement. The use of oatmeal in modern treatment is restricted to certain special cases, as exemplified below.

The *sudden* change from an unrestricted diet to one containing large amounts of protein and fat but limited carbohydrates is one of the most dangerous practices still encountered in diabetic treatment. The results may be an outbreak of coma as a result of destroying the balance between the fats and the carbohydrates of the diet.

Many diabetics break their diet because of the unreasonable restriction and lack of daily variation in their dietary prescriptions.

Fasting resembles digitalis as a therapeutic agent in being an excellent remedy only in skilled hands. By its means the patient is quickly rid of sugar; but such treatment is merely a useless hardship if the subsequent diet is not properly modified to maintain the patient permanently without glycosuria. Many physicians "treat the case" rather than aim to give the patient a systematic education with the aim of teaching him to live free of sugar.

PRINCIPLES OF MODERN DIABETIC TREATMENT

The object in the treatment of diabetes is to render the urine sugar free by fasting or by the employment of low caloric diets. This is done, for experience has taught that diabetics made permanently sugar free become rapidly relieved of symptoms and curable complications, and gain strength and resistance. The carbohydrate tolerance is usually increased by this treatment so that frequently increased amounts of starchy food can be assimilated with benefit. Acidosis is best combated by the same means in all but exceptional cases.

Hygienic Treatment.—The great emphasis necessarily placed on the diet in the treatment of diabetes has made many forgetful of the great importance of hygiene in the disease. Mental worry and strain should be excluded as much as possible, for I have seen diabetes apparently develop solely from this cause. Daily exercise in the fresh air should be prescribed for all but the very feeble. This is very important. Fresh air at work and during sleep, a rest in the middle of the day, and a change to a more hygienic occupation are other measures.

Classification of Diabetic Patients.—As the treatment of diabetes varies immensely with the severity of the case, it is important practically to divide diabetics into two groups as originally proposed by Joslin.

Group 1 comprises the light, uncomplicated cases — those showing, for example, only a few grams of sugar in the urine on an unrestricted diet. Such patients show slight clinical symptoms.

Group 2 comprises all severe, long-standing, complicated and acidosis cases; also cases with infection, and cases in the obese and elderly.

TABLE 1.—DR. JOSLIN'S DIABETIC CARD

FOODS ARRANGED APPROXIMATELY ACCORDING TO PERCENTAGE OF CARBOHYDRATES

	5 per cent.*	10 per cent.*	15 per cent.	20 per cent.
VEGETABLES (fresh or canned)	Lettuce Cucumbers Spinach Asparagus Rhubarb Endive Marrow Sorrel Sauerkraut Beet greens Dandelion greens Swiss chard Celery Tomatoes Brussels sprouts Watercress Sea kale Okra Cauliflower Eggplant Cabbage Radishes Leeks String beans Broccoli	Pumpkin Turnip Kohlrabi Squash Beets Carrots Onions Mushrooms	Green peas Artichokes Parsnips Canned lima beans	Potatoes Shell beans Baked beans Green corn Boiled rice Boiled macaroni
FRUITS	Ripe Olives (20% fat) Grapefruit	Lemons Oranges Cranberries Strawberries Blackberries Gooseberries Peaches Pineapple Watermelon	Apples Pears Apricots Blueberries Cherries Currants Raspberries Huckleberries	Plums Bananas Prunes
Nuts	Butternuts Pignolias	Brazil nuts Bk. walnuts Hickory nuts Pecans Filberts	Almonds Wal'ts(Eng.) Beechnuts Pistachios Pine nuts	Peanuts
Misc.	Unsweetened and unspiced pickle; clams; oysters; scallops; liver; fish roe			40 per cent. Chestnuts

* Reckon available carbohydrates in vegetables of 5 per cent. group as 3 per cent., of 10 per cent. group as 6 per cent.

(30 gm. 1 oz.) Contain Approximately	Carbohydrates Gm.	Protein Gm.	Fat Gm.	Calories
Oatmeal, dry wgt.	20	5	2	120

1 gm. fat	9 calories
1 gm. alcohol	7 calories
1 kg.	2⅕ pounds
30 gm. or c.c.	1 ounce

Treatment of Light Cases. (Group 1).—The patient is assisted to select from the Joslin food card (Table 1) a simplified diet corresponding as nearly as possible to his present diet without change. The patient is directed to weigh or measure all articles of his diet for the first few days of treatment. The various articles of food, for the sake of clearness, should be recorded in columns in a special notebook.

Instructions are given how to perform the qualitative Benedict test[3] for glucose in the urine. This test should be made by the patient himself on a twenty-four hour specimen or large mixed sample of urine. Several twenty-four hour specimens of urine should be tested quantitatively for glucose after the diet is being properly recorded.

The physician now calculates the approximate amount of carbohydrate in the diet, paying especial attention to the articles rich in carbohydrate, such as bread, milk, vegetables and fruit. There seems to exist an unreasonable objection on the part of the profession to accuracy in dietetic prescriptions. The calculations here suggested do not require over fifteen minutes daily. Protein and fatty foods are not calculated, but should be recorded for the patient's own instruction.

TABLE 2.—NEW DIET IN TREATMENT OF LIGHT CASES

Article	Amount Gm.	Amount Oz.	CH Gm.
10 per cent. vegetables	240	8	14
20 per cent. vegetables	120	4	24
Bread	60	2	36
Orange or grapefruit*	150	5	12
Total			86

* Edible portion.

The next step is to devise the new diet for the patient. This prescription should contain only about one half to two thirds of the amount of carbohydrate previously taken. Thus, if 150 gm. of carbohydrate were found to cause a few grams of sugar to be excreted in the urine, a maximum of 100 gm. of carbohydrate distributed somewhat as indicated in Table 2 can be ordered. The difference between this total and the 100 gm. of carbohydrate prescribed is allowed for by the 5 per cent. of vegetables, the cream, the cheese, etc., included in the general list.

TABLE 3.—GENERAL DIABETIC DIET LIST

Foods Permitted:
Soups—Clear meat broths, oxtail, green turtle, vegetable soup (use
only permissible vegetables). Casein, Hepco or Lister flour can
be used for thickening soups.
Meats—All kinds of meats, fresh, cured or smoked, except liver.
All meat must be prepared without flour or bread crumbs.
Eggs—Eggs in any form prepared without milk, flour or sweetening
(sugar, jam, etc.).
Butter—Butter, oils, lard, crisco, in moderate amounts.
Cheese—All kinds of cheese.
Fish—All kinds of fish, including canned salmon and sardines. Shell-
fish (oysters, clams, lobsters, scallops, crab, etc.) in small amounts.
Vegetables (containing 5 per cent. of carbohydrate)—Greens, spinach,
beet tops, string beans, Brussels sprouts, asparagus, lettuce, endive,
cucumbers, radishes, celery, cabbage, tomatoes, cauliflower, water-
cress, eggplant, kohlrabi, sour pickles.
Desserts—Gelatin jellies (flavored with sour white wine, brandy or
coffee), custards and ice cream made with eggs and cream only,
flavored with a little vanilla. All sweetening to be done with
saccharin or crystallose (do not use sugar or milk in desserts).
Beverages—Tea or coffee (without sugar or milk), cream and saccharin
may be used; claret; burgundy; sour white wine; whisky in
moderate amounts; Vichy and water. Cream to be used in coffee
and tea, or as desired in cooking.
Condiments—Pepper, salt, mustard, oil, vinegar, nutmeg, capers, cin-
namon, paprika, bay leaves.
Special—Nuts: butternuts, pecan nuts, Brazil nuts. Lister and Hepco
flour.

Avoid:
All articles not enumerated above. Patent diabetic foods in general.
Sugar in any form. Bread, biscuits, cake of any kind, toast, crackers.
All cereals (rice, oatmeal, cornmeal, sago, tapioca, hominy, etc.).
Macaroni, vermicelli, spaghetti. Potatoes and all vegetables not
listed above. All fruits, fresh, dried or preserved. Jellies, pastries,
puddings, ice cream. Sauces and gravies thickened with flour.
Catsup, chili sauce. Milk, ale, stout, porter, beer, cider, all sweet
wines, port wines, liqueurs, sparkling wines and syrups.

Less but not more than the prescribed amount of food may be taken. The noncarbohydrate food of the diet need not be especially prescribed except that the articles should be chosen from the general diabetic list (Table 3); that as little food as is necessary to maintain weight be eaten, and that fats never be used in excess. The final diet consists of known amounts of food rich in carbohydrates in addition to the general diabetic list. The weighing of the food may cease as soon as the patient has learned to estimate accurately the portions allowed.

The patient should become sugar free within one week on the new diet, if the work has been done correctly. This fact he establishes by his own urinary examinations controlled by the physician's. Later on the test should be made twice weekly, but never entirely omitted. If desired, the sugar can be immediately removed from the urine by a fast; but its gradual clearing up represents no danger to the patient, to whom this process is far more agreeable and is followed by as good results.

In many of these light cases the patients become sugar free by simply limiting the carbohydrate food without weighing. To this common procedure there are various objections. The greatest is that the training of the patient to dietetic accuracy is of fundamental importance to successful treatment. Again, if the upper limit of the carbohydrate content of the diet is ascertained by the patient's weighing and calculating the food, frequently certain amounts of bread, a little milk, fruit, etc., may be added with impunity, and the final diet be made much more endurable and agreeable.

Treatment of Severe Cases (Group 2).—Here acidosis or the danger thereof is present. It is most advisable to order no sudden change in diet at the start, for in certain cases even fasting if abruptly begun may cause acidosis to develop. To combat this condition the diet should be gradually reduced until a fast is finally instituted. Fasting is inadvisable in the elderly, and in nephritic, exophthalmic goiter and septic cases. The latter group of patients may fail to become sugar free even after prolonged abstinence from food. Here the use of restricted diets is indicated.

TABLE 4.—LIQUID DIET

WATER, TEA AND COFFEE—Without sugar, cream or milk, when desired. Crystallose or saccharin can be used for sweetening.
CHICKEN OR MEAT BROTH—May be taken every two hours. The broth should be clear, and not oversalted.
WHISKY—From 1 to 2 ounces can be taken for weakness. Do not remain in bed, but lie down if necessary.

1. The patient is trained to weigh and record the food without any radical change of diet at the beginning. The diet is simplified as before by omission of all complicated dishes and desserts, articles being chosen from the Joslin diet card.

The twenty-four hour urine specimens should be regularly collected and examined qualitatively and quantitatively[4] for glucose, and qualitatively for acetone, diacetic acid, and albumin. The patient's weight should be regularly recorded every second day. Marriott's alveolar carbon dioxid test may be carried out with advantage.

2. The fats are reduced by the omission of butter, lard, oil, cream, bacon, large amounts of cheese and meat, and all fried or greasy articles of food.

3. After the fatty foods have been omitted for a day or two, the chief protein foods in the diet are halved daily until none are taken. Such foods are meat, fowl, fish, eggs, milk and cheese.

4. The carbohydrate food in the diet is halved daily until fasting has been instituted. The patient fasts

---

[4] A simplified method for performing the Benedict quantitative glucose test is described in Joslin, E. P.: *Treatment of Diabetes Mellitus*, New York, 1917, p. 180, to which reference may be made for further details of diabetic treatment.

until sugar free for two days. The maximum duration of the fast is four days. The liquid diabetic diet is used (Table 4).

5. After the patient has been sugar free for two days, the fast is broken with the first diabetic diet, D_1 (Table 5), which supplies: carbohydrates, 12 gm.; protein, 53 gm.; fat, 22 gm.; calories, 450. If there has been no return of sugar on this diet, the second diabetic diet, D_2 (Table 6), is prescribed, which suplies: carbohydrate, 16 gm.; protein, 62 gm.; fat, 43 gm.; calories, 700. This may be given from a few days to a week or even longer. Then a trial is made with the third diabetic diet, D_3 (Table 7), which supplies: carbohydrate, 25 gm.; protein, 69 gm.; fat, 68 gm.; calories, 1,000. Finally, the fourth diabetic diet, D_4 (Table 8), may be used, which supplies: carbohydrate, 53 gm.; protein, 73 gm.; fat, 100 gm.; calories, 1,400.

TABLE 5.—DIABETIC DIET 1

Breakfast—	
Eggs, 2	
Vegetables, 5 per cent.	90 gm. = 3 oz.
Tea or coffee without sugar, milk or cream	
Dinner—	
Clear meat or chicken broth, fat skimmed off	1 cup
Lean round steak or lean chicken	60 gm. = 2 oz.
Vegetables, 5 per cent.	120 gm. = 4 oz.
4 p. m., or at bedtime—	
Clear meat or chicken broth, fat skimmed off	1 cup
Supper—	
Lean meat, fresh fish or lean chicken	60 gm. = 2 oz.
Vegetables, 5 per cent.	180 gm. = 6 oz.
Tea or coffee without sugar, milk or cream	

Approximate Totals—

Carbohydrates	Protein	Fat	Calories
12 gm.	53 gm.	22 gm.	450

TABLE 6.—DIABETIC DIET 2

Breakfast—	
Eggs, 2	
Vegetables, 5 per cent.	90 gm. = 3 oz.
Tea or coffee without sugar	
Milk	60 gm. = 2 oz.
Dinner—	
Clear meat or chicken broth, fat skimmed off	1 cup
Lean meat, fresh fish or lean chicken	90 gm. = 3 oz.
Vegetables, 5 per cent.	180 gm. = 6 oz.
Butter	10 gm. = ⅓ oz.
4 p. m., or at bedtime—	
Clear meat or chicken broth, fat skimmed off	1 cup
Supper—	
Lean meat, fresh fish or lean chicken	90 gm. = 3 oz.
Vegetables, 5 per cent.	150 gm. = 5 oz.
Tea or coffee without sugar

Carbohydrates	Protein	Fat	Calories
16 gm.	62 gm.	43 gm.	700

TABLE 7.—DIABETIC DIET 3

Breakfast—	
Eggs, 2	
Grapefruit or orange	90 gm. = 3 oz.
Vegetables, 5 per cent.	90 gm. = 3 oz.
Coffee or tea without sugar, cream or milk	
Dinner—	
Clear meat or chicken broth, fat skimmed off	1 cup
Lean meat, fresh fish or lean chicken	90 gm. = 3 oz.
Vegetables, 5 per cent.	150 gm. = 5 oz.
Vegetables, 10 per cent.	90 gm. = 3 oz.
Butter	15 gm. = ½ oz.
Cream cheese	30 gm. = 1 oz.
Supper—	
Egg, 1	
Lean meat, fresh fish or lean chicken	60 gm. = 2 oz.
Vegetables, 5 per cent.	150 gm. = 5 oz.
Butter	15 gm. = ½ oz.

Approximate Totals—

Carbohydrates	Protein	Fat	Calories
25 gm.	69 gm.	68 gm.	1,000

TABLE 8.—DIABETIC DIET 4

Breakfast—	
Eggs, 2	
Vegetables, 5 per cent.	90 gm. = 3 oz.
Orange or grapefruit	150 gm. = 5 oz.
Tea or coffee without sugar	
Milk	100 gm. = 3 oz.
Dinner—	
Lean meat, fresh fish or lean chicken	90 gm. = 3 oz.
Vegetables, 10 per cent.	120 gm. = 4 oz.
Vegetables, 20 per cent.	90 gm. = 3 oz.
Butter	30 gm. = 1 oz.
Supper—	
Lean meat, fresh fish or lean chicken	90 gm. = 3 oz.
Vegetables, 10 per cent.	120 gm. = 4 oz.
Butter	30 gm. = 1 oz.
Cream cheese	30 gm. = 1 oz.

Approximate Totals—

Carbohydrates	Protein	Fat	Calories
53 gm.	73 gm.	100 gm.	1,400

The butter in this diet can be used in the cooking. Olive oil (for salad dressing) may be substituted for it in part.

6. Repeated Fasting: If the patient still has glycosuria after breaking the initial fast by the D_1 diet for two days, he should fast again a maximum of three days and then take the D_1 diet again for three days, using thrice-washed 5 per cent. vegetables.[5] If the urine still shows sugar, a repetition of the fast, this time of two days' duration, followed by the D_1 diet with the thrice washed vegetables for four days, causes the glycosuria to vanish in nearly all cases.

When on this treatment the patient has been free of sugar for two days, the diet may be gradually increased under the fifth general scheme, but one should proceed very slowly.

7. Increasing the Diet: Even diets D_3 and D_4 are usually insufficient permanently to maintain weight and strength. As a general rule, patients should undergo treatment by fasting and very low dieting not longer than a period of three weeks' duration. After an interval varying with the severity of the case, attempts should be made gradually to increase the diet. In many cases the carbohydrates can be greatly increased if the fats are kept low, which also guards against acidosis. Many diabetics are held for too long a time to an overrestriction of carbohydrates, and do not do well in consequence.

Further increase in the foods may be made as follows: Carbohydrates may be added very gradually by (1) the substitution of 15 and 20 per cent. vegetables for the 5 and 10 per cent. varieties; (2) the giving of fruit; (3) the addition of small amounts of bread, and (4) the addition of oatmeal. Protein may be increased by the addition of eggs, meat, fish, milk or cheese; fats, by the addition of butter, cream, bacon or olive oil. It is usually more advisable to use cream in diabetes than milk, because of the increased caloric value and slightly lower carbohydrate content. Milk can be employed in dispensary work and in cases of high tolerance. By the addition of cheese and nuts to the diet, fats are introduced as well as protein.

8. Reappearance of sugar in the urine is the signal for fasting until sugar free, if there be no contraindication, and a lower diet containing but one half to two thirds of the carbohydrate.

Calculation of the Calories.—By the use of scales and the diet card, it is possible to calculate approximately the calories in a given diet. Thirty calories per kilogram or 2,100 calories for the average weight of 70 kg. should, in the opinion of Dr. F. H. Allen and myself, be the maximal adult diabetic ration. The caloric calculations can usually be avoided in general practice by (1) strict adherence to the diets, including daily weighing and recording of the food, and (2) careful observation of the patient's weight and general condition. As soon as the permanent diet on which the patient remains free of glycosuria and maintains body weight has been attained, the weighing of food can usually be dispensed with, and domestic measures, such as cream pitchers marked for the amount allowed, can be substituted.

---

[5] The vegetables are cleaned, cut up fine and soaked in cold water. They are then strained and tied up loosely in a piece of cheesecloth sufficiently large to permit the vegetables to swell without sticking together. They are placed in a saucepan containing a large quantity of cold water, and brought to the boiling point, at which temperature they are maintained for from three to five minutes. The water is then poured off, replaced with fresh water, and the vegetables are again boiled for the same length of time. This process is again repeated. The vegetables will keep for several days in cold storage, and may be reheated as desired.

Detection and Treatment of Acidosis.—The tests recommended as a routine measure for the detection and estimation of the degree of acidosis by the general practitioner are but three in number: (1) the ferric chlorid test[6] for diacetic acid; (2) the sodium nitroprussid test[7] for acetone, and (3) the Marriott quantitative method[8] for the determination of the alveolar carbon dioxid.

The acetone test really represents a more delicate index of the presence of diacetic acid than does the ferric chlorid reaction. A positive ferric chlorid test should lead to a Marriott carbon dioxid estimation. This test should be at the command of every one treating diabetics. The apparatus can be obtained from the Hynson, Westcott and Dunning Company, Baltimore (New York offices at 150 Nassau Street) for $5. The technic can be learned in a few minutes, and the results are most useful. When the tension of the alveolar carbon dioxid is normal, the reading of 45 will be obtained. Readings between 30 and 40 indicate a mild acidosis, while below 30 the case is more serious. Extreme values of 10 and 15 have been obtained in diabetic coma.

The effort should be made to render the urine free of sugar, and the qualitative as well as the quantitative acidosis tests negative. The ferric chlorid and acetone tests remain positive as long as the faintest trace of the acetone bodies is present. It must also be remembered that when the urine is kept sugar free, the acidosis usually clears up if given a little time. Too great a curtailment of the diet should not, therefore, be ordered on account of a mild ferric chlorid or acetone reaction. Considerable experience is necessary in applying the results of the acidosis methods to the treatment in a given case.

Coma and Its Treatment.—The early recognition of impending coma is of the utmost importance. On being called in consultation to see a diabetic who is said to be merely "not doing well," I have only too frequently found the patient, though conscious, bordering on coma. One of the earliest signs is a peculiar change in the facial expression. The patient presents the anxious appearance of one gravely ill. Quite a number of slight signs, if observed in time, may put the physician on his guard. Such are undue drowsiness, excitement, sudden failing of the appetite, nausea, headache, apparently causeless pains in various parts of the body, dyspnea or hyperpnea. It should be borne in mind that trivial factors may cause a predisposed patient to go into coma. Among these may be mentioned the pulling of a tooth, a tonsillectomy, and a severe nervous shock.

Treatment, if begun in time, may lead to recovery. One should avoid, if possible, alarming the patient. He should be kept *warmly* covered in bed. If the state of his stomach permits, he may be allowed to drink 4 ounces of hot liquid every fifteen minutes to half an hour, hot broth, tea, coffee and water being permissible. The bowels should be emptied immediately by an enema. Catharsis should be avoided. From 300 to 500 c.c. of hot physiologic sodium chlorid solution should be given by enteroclysis after the enema has been expelled. This should be followed with 500 c.c. of additional physiologic sodium chlorid solution by the drip method, once during six hours. If physiologic sodium chlorid solution is not retained, water should be used. It is essential to introduce 4,000 c.c. of liquid during the first twenty-four hours. Therefore if a sufficient quantity is not being retained by mouth and bowel, 700 c.c. of physiologic sodium chlorid solution should be given intravenously. A frequent mistake is to postpone the intravenous infusion until the patient is moribund. Given early, it may save life.

Diet.—Preferably only the liquids mentioned should be given, and from 30 to 40 gm. of carbohydrate in the form of the juice of three to four oranges for the twenty-four hours.

Medical Treatment.—Occasionally codein may be necessary to control vomiting and pain. Caffein may be given to the drowsy patient as a cardiac stimulant. Such cardiac stimulants as strophanthin, $\frac{1}{100}$ grain, are frequently indicated and forgotten in the excitement.

Alkalis in Acidosis.—The treatment as outlined is seen to be purely eliminative and supportive without the use of sodium bicarbonate. Views of even the best authorities are divided at present on the advisability of using alkalis. A final opinion as to the utility or uselessness of alkalis had best be reserved until the ultimate cause of diabetic coma is elucidated. Certainly the employment of large amounts of alkalis does much harm on account of the danger of upsetting the stomach, withdrawal of liquids from the body, and, in the case of intravenous introduction, the possibility of causing collapse. It has never been proved that the alkali treatment is beneficial even when small doses are administered. Indeed, a series of fifteen cases[9] with recovery from alarming acidosis or coma without the use of alkali has been reported.

STUDY OF THE BLOOD IN DIABETES

Much information can be gained by a study of the diabetic blood, which should be undertaken whenever possible. The blood methods used in diabetes are not emphasized in this article for the reason that the general practitioner frequently finds difficulty in having laboratory studies made, because of the lack of convenient first-class facilities and the expense. It is very advisable, however, to have blood sugar estimations made at intervals, for the height of the blood sugar is usually an indication of the severity of the disease as well as a gage of the effect of treatment. Normal blood sugar values range from 0.085 to 0.11 per cent., while in diabetes values up to from 0.20 to 0.40 per cent. and even higher are obtained. I have used the Epstein modification[10] of the Lewis-Benedict method with satisfaction. A few drops of blood from the finger tip is sufficient for a blood sugar determination.

In the treatment of acidosis patients too ill for the application of the Marriott alveolar carbon dioxid technic, a few cubic centimeters of blood may be withdrawn from the vein for a more careful study by the accurate Van Slyke method[11] for determining the carbon dioxid of the plasma.

---

[6] To about 10 c.c. of urine, a few drops of 10 per cent. ferric chlorid solution (aqueous) are carefully added. A precipitate of ferric phosphate may form first, but on addition of a few more drops, it dissolves. A Burgundy-red color indicates the presence of diacetic acid, the depth of the color being an index to the amount of the acid present.

[7] A few crystals of sodium nitroprussid are dissolved in a small amount of distilled water, 5 c.c. of the urine added, and the mixture rendered acid with a few drops of glacial acetic acid. This is stratified with ammonium hydroxid. A distinct purple appears at the point of contact, the width of the band depending on the amount of acetone in the urine.

TREATMENT OF OTHER COMPLICATIONS

Nephritis.—In acidosis cases, slight amounts of albumin and hyaline casts are frequently found in the urine. After the patient becomes sugar free, this condition usually improves. Actual nephritis is not uncommon. In such cases, fasting should be avoided, and the urine should be rendered sugar free by moderate reduction of the carbohydrate and the total calories. Only in uremic cases or in cases in which a blood urea determination proves nitrogen retention to be present should the protein of the diet be unduly curtailed. Nephritis is no contraindication to dietetic diabetic treatment, and improvement of both conditions is the rule with judicious management. Edema of nonnephritic origin is common in diabetic patients on low diets containing much salt. It may also be caused by the taking of large amounts of soda. Limitation of salt, omission of sodium bicarbonate, and sometimes restriction of the liquid intake relieve this condition.

Skin.—Great caution to avoid even the tiniest break in the contiguity of the skin is necessary. Daily bathing and the liberal use of talcum powder are indicated.

Pruritis Vulvae.—This usually clears up as soon as the urine is sugar free, if it is not dependent on some local cause.

Furuncles.—These are frequent in diabetes. The old warning to examine the urine in every case of boils is still sometimes neglected. Aside from surgery, furuncles may be treated locally by a 3 to 5 per cent. ammoniated mercury ointment with white petrolatum. A daily bath should be ordered, followed by a boric acid sponge over the entire body, to prevent extension of the infection.

Diabetic Gangrene.—This condition is the end-result of an occlusive angiitis. Prodromal symptoms include numbness and chilliness of the extremities, and intermitent pains lasting frequently for years. In this condition hot foot-baths, massage, short walks and elevation of the feet while at rest should be prescribed. Moist, hot compresses applied for brief intervals once or twice daily are helpful in relieving pain. The use of salicylates may lead to the appearance of a positive ferric chlorid reaction in the urine, when no acidosis is actually present. If actual gangrene develops, a surgeon should be called at once.

Sepsis.—It is sometimes difficult as well as injudicious to free a septic patient of sugar. Restricted diets may be badly borne. Supportive and stimulative measures may be required until improvement permits stricter treatment.

Pregnancy and Diabetes.—A small amount of glucose is not uncommonly found in the urine of pregnant women. In such cases the carbohydrate should be limited and special care be generally employed. Marked clinical symptoms of diabetes had best be regarded by the general practitioner as an indication for an early abortion, though in expert hands cases are now carried through successfully to confinement.

DIABETES IN CHILDREN

Children are especially liable to acidosis. One should be careful never to permit an unlimited amount of fat in the diet, and to restrict fatty foods during the minor illnesses to which children are susceptible. It should be remembered, however, that on account of growth about double the amount of food required by adults must be given to children. Happily, the life of diabetic children is becoming increasingly prolonged under modern treatment. One of my little patients has completed her eighth year, diabetes beginning at 5.

END-RESULTS IN THE PROSTATECTOMIZED PATIENT: A COMPARATIVE ANALYSIS

BASED ON ONE HUNDRED AND TEN CASES (FIFTY-FIVE SUPRAPUBIC, FIFTY-FIVE PERINEAL)*

CLARENCE MARTIN, M.D.
Captain, M. R. C., U. S. Army; Visiting Genito-Urinary Surgeon,
St. Louis City Hospital
ST. LOUIS

My natural interest, as a urologist, in the life of the prostatectomized patient after complete operative convalescence, particularly as it involved the several important functions subjected to surgical assault, prompted me, in 1917, to write to a considerable number of general practitioners for information of those of their patients on whom a prostatectomy had been done. I enclosed a printed questionnaire covering the following points:

When was operation performed?
Age of patient at operation.
Suprapubic or perineal?
Did wound heal promptly?
If urinary fistula resulted, how long was it in healing?
Present frequency of urination: (1) day; (2) night.
Has patient full control of bladder?
Has patient incontinence? Complete or partial?
Cystitis?
Pain: Connected with Urination? Independent of Urination? Location.
Amount of residual urine.
What force to stream?
Effect of operation on sexual power.
Increased, lessened or unchanged?
Was there stricture of urethra following operation?
Is urine clear?
Has there been stone formation since operation?
Effect of operation on patient's general health.

I chose the family physician as the source of my information because I believed he would be in closer touch with prostatectomized patients than the genito-urinary surgeon. When we have done the prostatectomy and returned the patient to his physician, we usually lose sight of him; but the continued and more intimate relationship between family physician and patient permits the general practitioner to pass accurate and unbiased judgment on the end-results of surgical procedures. Hence, I feel sure that the figures I am about to present represent more reliable conclusions than if they were based on the reports of the men doing the work. Fully to know a person, one must "summer and winter" with him. The family physician does this with his patients. The specialist does not.

The employment of a printed questionnaire secured uniformity of information.

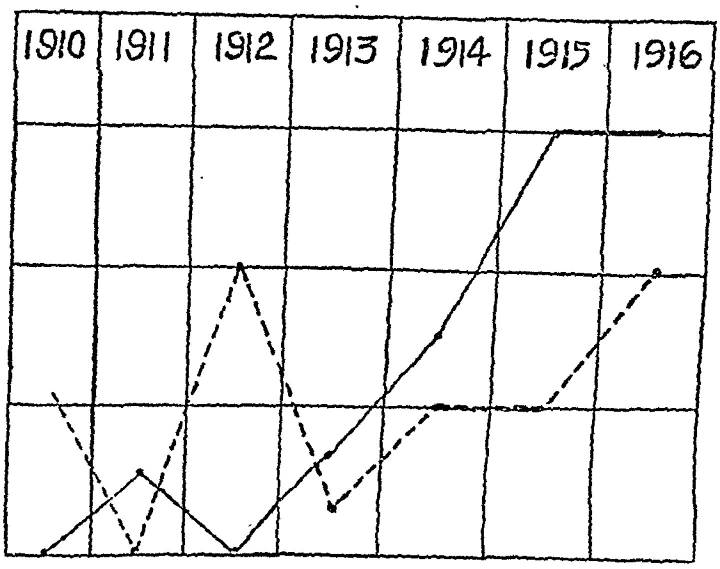
* Read before the St. Louis Medical Society, March 9, 1918.

COMPARISON OF THE TWO OPERATIVE PROCEDURES

Curiously enough, on the final balancing of my returns, I found that I had reports on fifty-five cases of suprapubic prostatectomy, and fifty-five in which the perineal operation had been performed. I was not so much struck by this exact balance of choice of operative procedure as I was by the fact that the perineal operation was still in large vogue. While it is true that in recent years the suprapubic operation has attracted by far the wider attention in the literature of prostatectomy, yet by glancing at the accompanying chronological chart, we may readily see that there is not the numerical disproportion between the two operations which most of us held to be the case. Even as late as 1916, as shown by the chart, the perineal was two thirds as popular as the suprapubic operation.

The fairness of the conclusions reached after a comparative analysis of these 110 cases becomes all the more obvious when one remembers the even balance of operative routes.

Some of the patients were operated on by myself, others by other urologists, general surgeons, general practitioners and gynecologists. Hence they represent a wide assortment of surgical talent.



Comparative popularity of the two operations: solid line, suprapubic; broken line, perineal.

As far as the age factor is involved, it is interesting to note that those subjected to the suprapubic operation were, on an average, a trifle more than two years older than those subjected to the perineal. The average age of the suprapubic patients was 66.5 years, and that of the perineal patients, 64.3 years.

It is true that hitherto the perineal route has had a smaller operative mortality than the suprapubic; but during the past few years the mortality figures of the two operations have been rapidly approaching each other, particularly since the two-step suprapubic operation has been popularized. In view of this reduction of suprapubic mortality, largely due to better control of the renal factor, the element of extra hazard does not participate so markedly as formerly in the choice of operative procedure. Furthermore, since the probable end-results of an operative procedure are a weighty factor in the determination of its feasibility and choice, it is obvious that even though there is a slight extra operative hazard, either actual or apparent, this is, in a very large degree, neutralized by superior end-results. After all, the end-result of an operative measure is the acid test of its applicability.

At this point, I wish to state that any apparent discrepancy between the mathematical determination of any single factor and the total number of cases is due to the fact that in some instances certain questions were unanswered. Illustrative percentages of the several items involved are based on the actual number of available answers to each individual question. Again, when answers were vague or obviously incorrect, they were not used in the estimation of findings.

Entering on the matter of immediate operative convalescence, we may generously grant that any prostatectomy wound that closes entirely within four weeks may be designated as having healed promptly. As shown in Table 1, 61.2 per cent. of the suprapubic cases in this series healed promptly as against 42 per cent. of the perineal cases. Of the suprapubic cases, 93.8 per cent. were healed within three months, while only 66 per cent. of the perineal cases closed up in the same period. Within one year following operation, the wounds in a full hundred per cent. of the suprapubic cases were entirely healed; of the perineal wounds, only 84 per cent. were healed by the end of the year. In other words, while every suprapubic wound had healed within a year, 16 per cent. of the perineal wounds were still discharging urine through a sinus. Carrying the analysis further, we find that in 6 per cent. of the cases of the entire perineal series, a permanent discharging sinus persisted. One of these cases presented a vesicorectal fistula, with the urine discharging into the rectum.

TABLE 1.—CLOSURE OF WOUND

	Suprapubic		Perineal	
	No.	Per Cent.	No.	Per Cent.
Healed promptly	30	61.2	21	42
Healed within 3 months	16	93.8	12	66
Healed within 1 year	3	100.	9	84
Sinus persisting beyond one year, finally closing	0	0.	5	10
Permanent fistula	0	0.	3	6

DIVERGENCE IN END-RESULTS

It is at this point that the end-results of the two modes of prostatectomy begin their wide divergence. Since these end-results are expressed in mathematical terms, they are the more readily grasped, and the element of personal bias is eliminated.

In the vast majority of cases of prostatic hypertrophy, the symptom forcing the patient to seek surgical aid is either intolerable frequency of urination, particularly at night, or retention. Of necessity, removal of the gland relieves the retention. Now let us examine the figures and see what degree of relief is secured from the inordinate frequency. While, of course, no sharply defined line between normal and abnormal frequency can be drawn, yet for the purpose of conveniently arriving at an approximate standard of normality, we may arbitrarily fix a three-hour period for the day and a four-hour period for the night.

From my questionnaire I received definite information on the day urination of thirty-seven suprapubic and of thirty-six perineal patients. The results are summarized in Table 2. Of the thirty-seven suprapubics, thirty urinate during the day at normal intervals, five every two hours, one every hour, and one every thirty minutes. In the thirty-six perineal cases, twenty-four of the patients were restored to normal diurnal frequency, ten can hold the urine only two hours and two must urinate every hour. There are no perineal cases in the thirty-minute class.

Expressing these results in percentages, we find, among the suprapubic cases, that they are good in 81, fair in 13.5 and poor in 5.4 per cent., while among the perineal cases the day results are good in 66.6, fair in 27.7 and poor in 5.5 per cent.

As we usually determine nocturnal frequency by the number of times a patient is compelled to arise from bed, I have thought it simpler to classify the night frequency in this manner, rather than to express it in periods of hours.

I have information on the nocturnal frequency of thirty-five suprapubic and thirty-eight perineal patients. At this point the parallel figures are quite impressive. Of the patients in the suprapubic cases, thirteen do not arise at night at all, sixteen only once or twice, two three times, and four oftener than three times.

On the other hand, in the perineal cases, only one patient passes the night without urinating; sixteen arise once or twice; nine three times, and twelve must get up oftener than three times. Thus we may say that of the thirty-five suprapubic cases, twenty-nine have a normal nocturnal frequency, whereas only seventeen of the thirty-eight perineal cases are as fortunate. The patients in nine of the perineal cases arise three times and in twelve oftener than three times.

TABLE 2.—PRESENT FREQUENCY OF URINATION IN SEVENTY-THREE CASES

	Suprapubic	Perineal
Day:		
Normal	30	24
Two hours	5	10
One hour	1	2
Thirty minutes	1	0
Night:		
Do not arise at all	13	1
Arise once or twice	16	16
Arise three times	2	9
Arise oftener than three times	4	12

Results expressed in percentages:

	Suprapubic		Perineal	
	Day	Night	Day	Night
Good	81	82.8	66.6	44.7
Fair	13.5	5.7	27.7	23.7
Poor	5.4	11.5	5.5	31.5

Since the correction of marked frequency, and especially nocturnal frequency, is an important purpose of prostatectomy, the gross figures and percentages covering this function form an index of no light value in prosecuting a comparative analysis of the two operations. My percentages demonstrate that, so far as day frequency is concerned, the suprapubic has a big lead over the perineal route, and a comparison of the night results shows that in suprapubic cases these results are almost twice as gratifying as in the perineal cases. While 82.8 per cent. of the suprapubic patients were restored to a very comfortable degree of night frequency, only 44.7 per cent. of the perineal patients were as fortunate, and whereas the night results in the suprapubic cases are poor in 11.4 per cent., among the perineal cases 31.5 per cent. may be so designated. In other words, the poor results of the perineal operation, as far as they relate to the important item of nocturnal frequency, are nearly three times as great as in the suprapubic series.

When we bear in mind the almost intolerable suffering that is consequent on an incontinent bladder, efforts to preserve the integrity of its function seem easily entitled to the most urgent consideration. The patient who returns home after a prostatectomy with a hopelessly incontinent bladder is not likely to hold his operation a success, even though it did effect the removal of his prostate gland.

Concerning this phase of our subject, I have definite information of forty-six suprapubic and fifty perineal cases, which is summarized in Table 3. Of the forty-six suprapubic patients, thirty-seven have full control of the bladder function, seven have partial control, and two have complete incontinence. Of the fifty perineal patients, thirty-two have full control, eleven have partial control and seven have complete incontinence. Expressed in percentages, these results loom up still more strikingly. While the patients in 80.5 per cent. of the suprapubic cases have full control, only 64 per cent. of the patients in the perineal cases are equally lucky. Of the suprapubic cases, 15.2 per cent. are put into the partial control designation, while 22 per cent. of the perineal cases must be so described.

TABLE 3.—CONTROL OF BLADDER

	Suprapubic		Perineal	
	No.	Per Cent.	No.	Per Cent.
Full control	37	80.5	32	64
Partial control	7	15.2	11	22
Complete incontinence	2	4.3	7	14

The suprapubic patients with complete incontinence embrace 4.3 per cent. of the entire suprapubic series, while 14 per cent. of the perineal cases are in this pitiable state.

In the examination of the various elements entering into the comfort of the prostatic postoperative life, only in the elements of persisting cystitis and pain do we find a balance in favor of the perineal route. By the figures set forth in Table 4, the questionnaire shows that 35 per cent. of the suprapubic patients complain of cystitis of varying grades, and 21 per cent. refer to definite pain at some point in the region of the site of operation. Of the perineal patients, 31 per cent. have cystitis and only 16 per cent. pain.

The answers relating to residual urine are too vague and inconclusive to be of substantial worth. Hence this factor will not be discussed.

As far as the force of the urinary stream is concerned, the figures so materially favor the suprapubic operation that I am sure the factor of urethral stricture must enter more deeply into the question of relative merit than we have hitherto thought. Of course, in working out the causes of reduced force of the stream, we must not forget the expulsive power of the bladder itself. I believe that in many instances the tonicity of the bladder is greatly improved on removal of the obstructing prostate; but if a stricture follows operation, this tonicity cannot be restored.

Of forty-two suprapubic cases investigated, twenty-two have a stream of good force, in eight the stream is fair, in twelve it is poor. In only twelve out of forty-six perineal cases is it good; in seventeen it is fair, and in seventeen poor. The percentage figures, as given in Table 5, show these results more graphically.

TABLE 4.—INCIDENCE OF CYSTITIS AND PAIN

	Suprapubic		Perineal	
	No.	Per Cent.	No.	Per Cent.
Cystitis:				
Present	16	35	15	31
Absent	30	65	33	69
Pain:				
Present	10	21	8	16
Absent	38	79	41	84

This suspicion of a preponderance of urethral damage following perineal prostatectomy becomes all the more clearly warranted when we examine the actual stricture reports. Among forty-six suprapubic cases there are three definite reports of stricture. Among forty-three perineal cases there are ten such reports. Expressed in percentages, these results are: suprapubic 6.5 per cent., perineal 23.2 per cent.

As the possibility of stricture formation is a most important element in the remote success of a prostatectomy, it is well to give this point the consideration its importance warrants.

Regarding the clarifying effect prostatectomy has on the urine, the two operative modes enjoy somewhat similar percentages, which are presented in Table 6.

However close in agreement the figures on the turbidity of the urine may be, we find in the percentages of stone formation a feature of considerable interest. Following suprapubic prostatectomy there was no stone formation in our series, while stone was formed in 4.1 per cent. of the perineal cases. Since lithiasis is favored through incomplete or difficult emptying of the bladder, with consequent urinary stagnation, we may look on stone formation as bearing a very close relationship to the factor of stricture formation.

TABLE 5.—FORCE OF STREAM

	Suprapubic		Perineal	
	No.	Per Cent.	No.	Per Cent.
Good	22	52.3	12	26
Fair	8	19	17	37
Poor	12	28.6	17	37

While with the majority of these old men, active sexual life has ceased to be a matter of grave concern, yet there are many who, discussing with me the immediate and remote dangers of prostatectomy, inquire seriously into the possibility of damaged sexual function. Hence the figures covering this phase are not without instructive value.

TABLE 6.—CHARACTER OF URINE

	Suprapubic		Perineal	
	No.	Per Cent.	No.	Per Cent.
Clear	30	65.2	31	67.4
Turbid	14	30.4	14	30.4
Variable	2	4.4	1	2.1

On this postoperative phase I have information touching on thirty-three suprapubic and thirty-three perineal cases, a similarity that makes the figures given in Table 7 easier of comparative understanding. In twenty-one of the suprapubic cases there was no change effected in the sexual function, in nine it was diminished and in three increased. In the perineal series this function was unchanged in sixteen cases, diminished in sixteen, and increased in only one. Here it should be remembered that the patients in the suprapubic cases are, on an average, two years older than those in perineal cases.

TABLE 7.—EFFECT ON SEXUAL POWER

	Suprapubic		Perineal	
	No.	Per Cent.	No.	Per Cent.
No change	21	63.6	16	48.5
Diminished	9	27.3	16	48.5
Increased	3	9.1	1	3

Naturally the effect of prostatectomy on the general well-being of the patient is of the utmost importance, and the figures describing this item should be carefully digested. Among forty-three of the patients in forty-nine suprapubic cases, the effect on the general health was good, in three it was bad, and in three patients there was no change. In thirty-six of the forty-seven perineal cases the effect was good, and in four it was bad, with no change in seven. A glance at Table 8 shows that in this important feature of prostatectomy, the suprapubic operation has a big lead over the perineal.

CONCLUSION

It is well that the perineal operation is losing popularity, for in this careful analysis of results, only in three inconsequential features is an advantage to be found for this route in the parallel figures. In all the important features the suprapubic operation has a big lead, showing beyond the shadow of a doubt that, measured in end-results, suprapubic prostatectomy is vastly superior to the perineal operation.

TABLE 8.—EFFECT ON GENERAL HEALTH

	Suprapubic		Perineal	
	No.	Per Cent.	No.	Per Cent.

GLOBULES OF METALLIC MERCURY IN THE TISSUES

FINDINGS IN AN AORTIC ANEURYSM WITH EROSION OF THE VERTEBRAE *

JOHN A. KOLMER, M.D.
AND
E. V. MASTIN, M.D.
PHILADELPHIA

The case here reported is one of considerable interest in view of the finding at necropsy of numerous globules of metallic mercury in the tissues of an aneurysm of the aorta, and the eroded vertebrae of the spinal column. *Myriads of minute globules of mercury were scattered throughout these tissues, the metal* being easily expressed and collected into larger globules in the concavity of the aneurysm and eroded tissues.

The deposition of the metal in the actively eroding and necrotic tissues, and probably primarily in the necrotic vertebrae, constitutes a finding of unique interest and considerable importance, although by no means rare or unusual. As early as 1579, Fernel[1] states, in his work on the venereal disease, that metallic mercury may be found in the "putrid caries of bones" if the patient has been exposed to the vapor of mercury or of cinnabar, and also in those who have had repeated rubbings with the ointment. Since then, several observers have recorded the presence of metallic mercury in the necrotic bones of syphilitics receiving vigorous mercurial treatment; the literature of the last twenty-five years, however, contains but few records, owing probably to the practice of less vigorous dosage with mercury in the treatment of syphilis.

That mercury may be found by chemical methods in the brain, liver and other internal organs following its administration by inunction, subcutaneous and intramuscular injections of soluble and insoluble salts, or by swallowing, is well established; Fernel believed that the mercury as such was transported to these organs, but this result is now regarded, according to Hallopeau,[2] as due to successive combinations (as mercury albuminate) and decompositions, ending by the formation of a soluble salt and pure metal, or a reducible insoluble salt. The method of administration of mercury in those instances in which the metal itself was found in the tissues is not always stated; but in most of them it would appear that the drug was given in the form of inunctions with mercurial ointment; unfortunately we were unable to learn from our patient the treatment he had received from various physicians. The suggestion has also been made that mercury may be transported in the body fluids in a colloidal state, its absorption and deposition in the tissues being placed on a physicochemical basis; the subject requires further study and elucidation.

---

* From the Laboratories of the Philadelphia Polyclinic.

[2] Hallopeau, H.: *Du mercure; action physiologique et thérapeutique,* Paris, 1878.

It is also of interest to note that metallic mercury has been found chiefly in necrotic bones. In our case globules were found not only in the necrotic vertebrae, but also in the inflammatory soft tissues of the aneurysm. In a second aneurysm, however, without involvement of bone, we were unable to find metallic mercury.

While mercury has an apparent protoplasmic affinity for the *Spirochaeta pallida,* explaining the specificity of the drug in the treatment of syphilis, the deposition of mercury in the tissues bears no relation to the distribution of spirochetes; we were unable to find spirochetes in the eroding mercury-laden aneurysm, and numerous chemical studies have shown the presence of mercury in the liver and other internal organs of otherwise normal experimental animals, as recently described by Schamberg, Kolmer, Raiziss and Gavron,[3] and also in healthy rabbits following inunctions of mercurial and calomel ointments. So far as the deposition of metallic mercury is concerned, it would appear that this occurs by reason of chemical changes in necrotic tissues of syphilitic or nonsyphilitic etiology; Blundell has recorded the finding of scores of globules of mercury in the tissues of a fly blister in the epigastric region in a person who took half an ounce of metallic mercury for cathartic purposes.

REPORT OF CASE

The main features in the clinical history and necropsy of our case were as follows:

A negro man, aged 40, admitted to the medical wards of the Polyclinic Hospital, September 24, 1916, in the service of Dr. R. Max Goepp, complained of dyspnea, blood stained sputum, dry cough, a sense of pressure in the throat that rendered respiration difficult, and pains throughout the thorax. The patient died two days after admission with symptoms of suffocation; a clinical diagnosis of aneurysm of the arch of the aorta had been made.

The patient had had the usual diseases of childhood, but no other illnesses until fifteen years before admission, when syphilis was contracted, a chancre on the penis being followed three weeks later by a general rash. He had been addicted to the use of alcohol and tobacco for many years.

According to the patient's statements the present symptoms began about three and a half months before admission to the hospital. A sensation of choking and a dry, harassing cough induced him to consult several physicians, two of whom diagnosed "bronchitis" and "asthma," respectively. The dyspnea gradually became worse, and severe shooting pains developed in the left side of the thorax, particularly over the precordial area, radiating to the left shoulder, to the base of the neck and along the spine on the left side. A slight hemorrhage from the mouth occurred two days before admission to the hospital. Physical signs of aortic aneurysm were elicited; the urine contained albumin and casts; the Wassermann reaction was strongly positive.

At necropsy a severe aortitis and two aneurysms were found. The first aneurysm was fusiform in shape and involved the first portion of the descending aorta. This aneurysm was pressing on the trachea and esophagus, but had not produced ulceration of these structures. The mucous membrane of the trachea and bronchi of both lungs was considerably thickened, congested and covered with a thick tenacious mucus. No actual erosion of a blood vessel was found, and the one slight hemorrhage occurring during life may have been due to the rupture of a small vessel in the inflamed mucosa of the trachea during an attack of coughing. The smaller bronchi contained considerable mucopurulent material, and the right lung several patches of an early bronchopneumonia.

The second aneurysm occurred at a point just above the passage of the aorta through the diaphragm, and had produced considerable erosion of the bodies of the second, third, fourth and fifth dorsal vertebrae on the left side and the contiguous ribs. Several small clots of blood were found in various cavities within this larger cavity. During the manipulation of the tissues consequent to the removal of the specimen, several large globules of metallic mercury were found to have collected. Minute inspection of the tissues showed the presence of myriads of pure globules of mercury scattered throughout the remainder of the wall of the aneurysm and the eroded tissues of the vertebrae.

Mercury was not found microscopically in the first mentioned aneurysm or in any other organ or tissue.

Sections of the heart, aorta, both aneurysms, lungs, trachea, spleen, liver, kidneys, suprarenal glands, and other tissues stained by the method of Levaditi and also with Warthin's modification, did not show the presence of *Spirochaeta pallida.* Sections of the tissues of the mercury-bearing aneurysm showed numerous cavities and spaces previously occupied by the mercury, some with and many without surrounding lymphocytic infiltration; with tissues embedded in paraffin and celloidin the globules invariably escaped during the process of cutting, although occasionally very small masses remained.

Unfortunately the patient could not remember the names or addresses of several of the physicians whom he consulted and whose medicines he took; for this reason we were unable to ascertain how much mercury was taken and the route of administration. There can be but little doubt, however, that mercury was administered: and the deposition of the metal in the active eroding lesions, and probably primarily in the vertebrae, constitutes a finding of unique interest and considerable importance.

Thirst at Sea.—M. Roberts suggests that persons suffering from thirst at sea might find relief by injecting sea water into the rectum. He writes to the *British Medical Journal,* Feb. 16, 1918, p. 220, to describe an experience by Mr. R. Graham, who undertook a fast during a sea voyage and while fasting injected daily 2 gallons of pure sea water. "During the first five days he did not take anything to drink although the fourth and fifth days he rinsed out his mouth with ordinary water. He did not feel in the least thirsty until the sixth day, when he took half a glass of water. Thirst was very slight. On the seventh day he drank one and one-half glasses of water although he felt he could have gone without had he chosen to do so. During this period his pulse was normal, his general condition good, his strength well maintained and though the injections resulted in the usual evacuation there was no tendency to diarrhea or other disturbance. On the eighth day he resumed his normal life." Roberts suggests that with a rectal syringe as part of the boat's normal equipment the lives of seamen and others dying of thirst, even this last year, might have been saved. Injections of sea water are used as a routine measure in Lieutenant-Colonel Wherry's service, he writes. He adds that in an emergency a rubber tube might be used as a siphon or the nozzle and bowl of a tobacco pipe. He commends the suggestion for the slow injection of sea water as an enema for absorption, although he knows of no navigator who has tried it.

CONTROL OF POLYURIA IN A CASE OF DIABETES INSIPIDUS

BY MEANS OF HYPOPHYSIAL EXTRACT

JACOB ROSENBLOOM, M.D., Ph.D.
PITTSBURGH

It is gradually becoming known that certain cases of diabetes insipidus are due to an underfunction of the pars intermedia of the hypophysis, and that in these cases the polyuria may be controlled by the injection of hypophysial extract. The case I am about to report, which is a typical case of hypopituitarism with diabetes insipidus, shows well the effect of this therapy.

Barker and Mosenthal[1] have described a case of diabetes insipidus treated by pituitary solution, and they present the literature in relation to the subject. Barker and Hodge[2] also described a case in a multiglandular endocrinopathy so treated.

David S., a boy, aged 12½ years, had urinated excessively since he was 3½ years of age. In the last year of that period, his mother had noticed that his eyesight was getting bad. His mother, father and sister were well.

The physical examination was negative with the exception of the presence of a bilateral temporal hemianopsia. The Wassermann and leutin tests were negative. A roentgenogram of the brain showed a normal sella turcica. The diagnosis of diabetes insipidus with a possible suprasellar cyst of the pituitary was made. On account of the lack of pathologic conditions in the sella turcica and the absence of erosion of the clinoid processes, it was decided that the growth was out of the sella turcica. Because of the fact that the condition had been present for nine years, it was considered cystic rather than malignant, and the presence of the hemianopsia revealed the fact that there was pressure on the optic tracts.

The accompanying table shows the fluid intake and output and the influence of the treatment on these two factors. The table shows very clearly the control of the polyuria by means of the pituitary solution. It also shows that the thyroid extract does not have any effect on the polyuria. The ingestion of pituitary gland does not affect the polyuria. The effect of the injection of the pituitary solution lasts only about twenty-four hours. It may be noticed that after the injection the urine shows some pigment, not having the water-clear color of the usual urine. As the effect of the pituitary solution wears off, it may be noticed that the urine again becomes pale.

INTAKE AND OUTPUT OF FLUIDS

THE TOTAL BLOOD VOLUME IN PERNICIOUS ANEMIA

EDWARD LINDEMAN, M.D.
NEW YORK

In a preliminary report,[1] I described a new method for the estimation of the total volume of blood in anemia.

In no disease is it of greater importance to know the volume of blood in the body than in pernicious anemia. We find patients in this disease bearing their illness variably, though the degree of anemia in all may be the same. In many the same group of symptoms are present, varying only in intensity. I believe that individual peculiarities may account for differences in the intensity of symptoms, and that also some differences may possibly be accounted for by varying degrees of toxicity; nevertheless, the main factor, in my opinion, is the hitherto unrecognized importance of blood volume.

Rancke has demonstrated that the blood is thus distributed in the various organs: In the rabbit, one-fourth to the heart, lungs and great vessels; one-fourth to the resting muscles, and one-fourth to the remaining organs. In man, to the spleen, 0.23 per cent.; to the brain and cord, 1.24 ; to the kidneys, 1.63; to the skin, 2.10; to the intestine, 6.30; to the bones, 8.24; to the heart, lungs and great vessels, 22.76; to the resting muscles, 29.20, and to the liver, 29.30 per cent. According to Rancke, therefore, a man (Case 3) with a 30 per cent. hemoglobin and a blood volume of 1,600 c.c. has an amount of blood nourishing his brain that is the equivalent of 6.5 c.c. of normal blood. If we assume that this man normally would carry 5 liters (quarts) of blood in his body, then the brain would be nourished by 62.5 c.c. of blood containing 100 per cent. of hemoglobin.

It is very singular and startling, in view of all we have previously been taught about the amount of blood that may be lost before life becomes extinct. The literature tells us that a loss of half the blood will in most cases produce death. Yet, in the case cited below, the blood in the brain of this individual is reduced to one-tenth that of a normal person without an approach to even partial unconsciousness. As a matter of fact, this man's brain (Case 3), if anything, was in a hyperexcitable condition whereby he was enabled to perform business tasks of large proportions with unusual keenness, in marked contrast to his physical condition, which was very desperate.

In this case, the intestine, according to Rancke's figures, was nourished by an amount of blood equal to 34 c.c. with 100 per cent. of hemoglobin, whereas if this man were normal, the intestine would be perfused by a volume of 315 c.c. of blood containing 100 per cent. of hemoglobin. Is it at all singular that such a patient should suffer severe gastro-intestinal disturbances with loss of appetite and nausea? Indeed, it is remarkable that his symptoms were not worse; and the prompt restoration of appetite and relief from gastro-intestinal disturbances are the most striking things that occur after the blood transfusion in such cases.

---

[1] Lindeman, Edward: A New Method for Estimating Total Blood Volume in Anemia, The Journal A. M. A., April 27, 1918, p. 1209.

I have observed that in the cases of anemia of the same or even of greater degree in which there is a larger blood volume, the gastro-intestinal disturbances are less severe. It is evident, therefore, and imperative that every effort should be employed to produce a high blood volume and to maintain it. A patient can tolerate his disease with greater comfort and with a feeling of well-being. Despite the anemia, he becomes less discouraged and is more inclined to take food. The increased quantity of food, especially liquids, will increase his blood volume, and a favorable cycle may be established. An increased consumption of food favors blood regeneration and may be regarded as a favorable sign in this disease. Naturally any depressing influences, such as sepsis, bad teeth, worry, intestinal disorders, etc., must be eliminated so that the regenerative power of the patient may not be suppressed.

I think we are apt to exaggerate the relationship of the teeth in this disease. I have seen cases in which a distinct slump followed the removal of bad teeth, out of proportion to other crises; and the course in these cases was no more favorable after the removal of the teeth than before. That, however, is another phase that does not interest us particularly here, excepting as a comment in restraining an overzealous enthusiast.

The ringing in the ears and the palpitation of the heart, which are frequently very distressing to a patient, are due not alone to the quality but more largely to the diminution of the quantity of the blood. Thus a patient with a larger blood volume will bear a greater degree of anemia without experiencing palpitation of the heart (often spoken of as fluttering) or roaring in the ears. Another quite frequent symptom of this disease is weakness, with exhaustion and syncope.

It is surprising how well some patients can go about and even sometimes perform laborious tasks in the face of a severe grade of anemia. I intend to show that this is possible only when there is a relatively large blood volume. When the blood volume is small, a less degree of anemia will produce a greater degree of exhaustion, weakness and faintness.

While it is evident that a shrunken blood mass intensifies the symptoms enumerated, it is not sufficient simply to restore the bulk of the blood. The bulk of blood is only one of the factors to be corrected. It is of the greatest importance to increase and maintain the richness of the blood not only in terms of red cells and hemoglobin but also in ferments, salts, proteins, alkali capacity, etc.

In spite of the relative hydremia to cell volume in pernicious anemia, if the blood volume is reduced 50 or 60 per cent., even though the salts, ferments and proteins may be of normal percentage, there is a great impoverishment in these elements proportional to the diminution in blood volume. Blood analyses in these cases, therefore, are necessarily incomplete without a knowledge of the blood volume. I am certain that many pathologic factors will be revealed by chemical analyses in the light of blood volume which have not heretofore been detected.

The method for calculating blood volume I have already described.[1] It is based on percentage relationships of cell volumes before and after transfusions according to the formula:

$$x = \frac{lb - bc}{a - l}$$

x = initial blood volume
a = percentage by volume of red blood cells
b = volume introduced by transfusion of blood
c = percentage by volume of the volume of red blood cells introduced by blood transfusion
l = final percentage by volume of red blood cells

REPORT OF CASES

Case 1.—A man, aged 45, weighing 150 pounds, and 5 feet 10 inches in height, had been ill with the disease five months. His teeth were bad. No transfusion had been performed. He was dyspneic from air hunger. He was very drowsy, and partially comatose. He was pallid, and had lost strength. His appetite was poor, and he suffered from nausea. He moaned frequently because of his distress. He was too weak to walk.

TABLE 1.—BLOOD AND RESPIRATION IN CASE 1

	Before Transfusion	After Transfusion
Red blood cells	800,000	2,216,000
Hemoglobin, per cent.	15	40
Respiration	24-28	20-24
Pulse	96	66-72
Blood Pressure—		
Systolic	115	140
Diastolic	60	70
Cell volume, per cent.	12.16	24.8

The cell volume of the donor was 46.64 per cent.; 1,222 c.c. of blood were transfused; 67 c.c. of blood were withdrawn for analysis before transfusion.

Blood volume = 2,103 c.c. + 67 c.c. = 2,170 c.c. = 3 per cent., or one thirty-third of the body weight.

The patient felt and showed a very striking improvement as soon as he had received 160 c.c. of blood. At this stage of the transfusion, the improvement cannot be accounted for by the increment of red blood cells and hemoglobin, but is to be attributed rather to the improved blood volume. There was continued improvement throughout the transfusion. Pallor, drowsiness and weakness rapidly disappeared, and the patient's appetite improved the following day. He walked about in a few days.

There were no chills. After the transfusion there was a rise of temperature of 2 degrees.

Case 2.—A man, aged 59, weighing 150 pounds, and 5 feet 7 inches in height, had been ill with the disease fourteen months. Transfusions had been performed, July 5, Sept. 19 and Dec. 5, 1917, with 1,800, 1,600 and 1,500 c.c., respectively. There were no chills, and there was a postoperative rise in temperature of 2, 3 and 2 degrees.

Jan. 29, 1918, there was a red blood count of 2,600,000, and the hemoglobin was 50 per cent. The patient's condition was good.

February 1, two abscessed teeth were extracted.

February 14, the condition of the patient before transfusion was very grave. There were great weakness, prostration, loss of appetite, sore mouth, nausea and vomiting, very slow mentality, forgetfulness, slurring speech, palpitation of the heart, a temperature of from 101 to 102, dyspnea on exertion only, and a roaring and thumping noise in the ears. There was no edema. A transfusion of 1,500 c.c. was performed. There was no chill. There was a rise in temperature of 2 degrees.

Seventy c.c. of blood were removed before transfusion.

TABLE 2.—BLOOD AND RESPIRATION IN CASE 2

	Before Transfusion	After Transfusion
Red blood cells	1,200,000	3,200,000
Hemoglobin, per cent.	30	68
Respiration	26-30	20-22
Pulse	104	72
Cell volume, per cent.	10	26.77

The cell volume of the donor was 51.3 per cent.

Blood volume = 2,131 c.c. + 70 c.c. = 2,201 c.c. = 3 per cent., or one thirty-third of the body weight.

When the patient had received 100 c.c. of blood he began to experience marked improvement.

Immediately after the transfusion, all the symptoms disappeared, and a few days later the patient walked about and went to business. His mental condition cleared up spontaneously.

Case 3.—A man, aged 63, weighing 135 pounds, and 5 feet 6 inches in height, had been ill with the disease two and a half years. There had been complete absence of hydrochloric acid in the stomach for twenty years before the present illness, but no evidence of this disease had been present up to two and a half years before.

The first transfusion, of 1,500 c.c., was performed, March 15, 1915. There were no chills and no rise of temperature.

Splenectomy was performed, March 24, 1916.

The second transfusion, of 1,400 c.c., was performed, July 14, 1916. There was no chill. There was a rise in temperature of 3 degrees.

The third transfusion, of 1,400 c.c., was performed, May 10, 1917. There was no chill. There was a rise in temperature of 2 degrees.

Four weeks prior to the third transfusion, the patient had several carious teeth extracted. This was followed by a bad slump in his blood and general condition.

The fourth transfusion, of 1,700 c.c., was performed, Sept. 11, 1917. There was no chill. There was a rise in temperature of 4 degrees.

Just before the fifth transfusion the patient was in a desperate condition and was apparently in the terminal stage of his disease. There were extreme weakness and prostration, nausea and vomiting, complete aversion to food, and eructations of quantities of gas. He was unable to walk or sit up on account of weakness. There was no paralysis. He was short of breath without exertion, he moaned constantly because of distress, and he was the picture of a complete physical wreck. In striking contrast to his physical was his mental condition, which was unusually active; he was keen to a degree almost uncanny. He performed many complicated mental tasks with remarkable celerity. He retained a vivid and acute memory of the remote past even better than the other members of his family. In brief, it seemed as though the inhibitory mechanism governing his mental activities was released and that his cerebration was accelerated by irritation due to an impoverished blood stream.

Jan. 10, 1918, 1,400 c.c. of blood were transfused. There was no chill nor rise of temperature. Ninety c.c. of blood were withdrawn before transfusion.

TABLE 3.—BLOOD AND RESPIRATION IN CASE 3

	Before Transfusion	After Transfusion
Red blood cells	1,800,000	3,500,000
Hemoglobin, per cent.	36	70
Respiration	32	22
Pulse	108	76
Blood Pressure—		
Systolic	110	130
Diastolic	80	85
Cell volume, per cent.	18.2	31.3

The cell volume of the donor was 45.5 per cent.

Blood volume = 1,518 c.c. + 90 c.c. = 1,608 c.c. = 2.4 per cent., or one fortieth of the body weight.

The relatively high cell volume may be compared with that in Case 5, the difference in blood volume, and also the physical state.

There was a prompt disappearance of all symptoms after the transfusion, and an increasingly rapid return of strength and appetite. The patient was less excitable, and he became quite calm and normal. He walks about his home, drives about town, and attends the theater twice weekly.

Case 4.—A man, aged 60, weighing 160 pounds, and 5 feet 2 inches in height, had been ill with the disease two years. He had been treated for a period of about fifteen months with the usual medication, to which he responded very well in the first two crises. The blood pressure varied considerably, and in the height of his anemia it rose to 240 systolic, and 140 diastolic. When the blood condition improved, the blood pressure dropped and at one time reached a systolic of 140 and a diastolic of 80. During the past six months, however, while he has been under my observation at frequent intervals, his blood pressure average has been between 180 and 190 systolic, and between 80 and 90 diastolic.

In July, 1917, he developed angina pectoris, from which he suffered considerably. At first the attacks were controlled satisfactorily by nitrites, but later these failed to afford relief. In July and August, when nitrites had failed, he was given small transfusions at intervals of from one to two weeks, and the angina was promptly relieved after each transfusion. Later these small transfusions failed to influence the angina. I was called in consultation by Dr. Stockton of Buffalo and Dr. Leonard of North Tonawanda in September, 1917. I then advised large transfusions. I performed transfusion, Sept. 14, 1917; 1,200 c.c. of blood were given. There was a prompt disappearance of angina for a period of about seven weeks. There were no chills. The temperature rose 3 degrees.

Transfusion was repeated whenever the angina recurred, with prompt relief, and the patient remained free of any attacks during the interim indicated by the following dates:

October 27, a transfusion of 1,440 c.c. was performed. There was no chill. There was a rise in temperature of 1 degree.

November 25, a transfusion of 1,000 c.c. was performed. There was no chill. There was a rise in temperature of 1 degree.

December 20, a transfusion of 500 c.c. was performed. There was no chill. There was a rise in temperature of 1 degree.

December 29, a transfusion of 1,489 c.c. was performed. There was no chill. There was a rise in temperature of 1 degree.

Jan. 23, 1918, the patient's condition was one of loss of appetite, weakness, and return of angina. He walked, but with considerable effort.

January 24, a transfusion of 1,600 c.c. was performed. There was no chill. There was a rise in temperature of 1 degree; 80 c.c. were withdrawn for analysis.

TABLE 4.—BLOOD AND RESPIRATION IN CASE 4, JANUARY 24

	Before Transfusion	After Transfusion
Red blood cells	2,080,000	3,950,000
Hemoglobin, per cent.	48	72
Respiration	24	20
Pulse	72	60
Blood Pressure—		
Systolic	190	185
Diastolic	90	85
Cell volume, per cent.	21	30

The cell volume of the donor was 41 per cent.

Blood volume = 2,079 c.c. + 80 c.c. = 2,159 c.c. = 2.8 per cent., or one thirty-fifth of the body weight.

February 24, the condition of the patient was excellent in every respect excepting for the recurrence of his angina in the past thirty-six hours. The appetite and strength were very good. The patient had gained 15 pounds in weight since January 24, and there had been no edema.

February 20, a transfusion of 1,650 c.c. was performed. There was no chill. There was a rise in temperature of 0.5 degree; 76 c.c. of blood were removed before transfusion.

TABLE 5.—BLOOD AND RESPIRATION IN CASE 4, FEBRUARY 20

	Before Transfusion	After Transfusion
Red blood cells	2,240,000	4,900,000
Hemoglobin, per cent.	55	78
Respiration	24	20
Pulse	68	60
Blood Pressure—		
Systolic	195	200
Diastolic	95	100
Cell volume, per cent.	25.24	30.05

The blood volume of the donor was 40.2 per cent.

Blood volume = 2,889 c.c. + 76 c.c. = 2,965 c.c. = 3.53 per cent., or one twenty-eighth of the body weight.

The blood analysis indicates a case of hypertension. The electrocardiogram demonstrates considerable involvement of the myocardium. This is the first case to my knowledge of pernicious anemia with a complication of angina pectoris.

Up to this time the angina has not recurred.

Blood volume after the last transfusion = 4,549 c.c. = 5.42 per cent., or one eighteenth of the body weight.

CASE 5.—A man, aged 43, weighing 130 pounds, and 5 feet 7 inches in height, had been ill with the disease two and one-half years. The teeth were excellent. Roentgenoscopy of the teeth, etc., was negative.

The first transfusion, in June, 1916, of 1,400 c.c., had not been followed by a chill. There was a rise in temperature of 4 degrees.

The second transfusion, Sept. 4, 1917, of 1,460 c.c., had not been followed by a chill. There was a rise in temperature of 2 degrees.

The symptoms noted immediately before the third transfusion were slight palpitation, a moderate thumping and roaring noise in the ears, some weakness, no prostration, loss of appetite, slight nausea, and no vomiting. The patient's mental condition was excellent. The general condition was fairly good. He was able to attend his occupation to within a few days of his last transfusion. Sensory disturbances of the limbs existing at the time of the first transfusion and for a period of about eight months afterward have entirely disappeared.

Dec. 19, 1917, transfusion of 1,603 c.c. was performed. The amount removed before transfusion was 90 c.c.

TABLE 6.—BLOOD AND RESPIRATION IN CASE 5

	Before Transfusion	After Transfusion
Red blood cells	1,360,000	2,800,000
Hemoglobin, per cent.	30	65
Respiration	24	20
Pulse	84	72
Blood Pressure—		
Systolic	120	140
Diastolic	65	75
Cell volume, per cent.	13.675	24.675

The cell volume of the donor was 48.9 per cent.

Blood volume = 3,520 c.c. + 90 c.c. = 3,610 c.c. = 5.78 per cent., or one nineteenth of the body weight.

After the transfusion, the patient was able to perform his duties with disappearance of all symptoms.

The difference in the condition of this patient should be compared with that of others of lower blood volume.

CASE 6.—A woman, aged 60, weighing 139 pounds, and 5 feet 4 inches in height, had been ill with the disease one and one-fourth years.

In April, 1916, she was operated on for cholecystitis. The gallbladder was drained, and the appendix removed. No stones were found. A large amount of bile was present. The appendix was normal.

The teeth were false excepting the lower five teeth in front, which were in good condition.

Symptoms before transfusion were weakness, nausea, vomiting and persistent cough. The patient was generally uncomfortable. She was able to walk, but with difficulty.

Feb. 7, 1918, the first transfusion, of 1,270 c.c., was performed; 66 c.c. of blood were withdrawn before transfusion.

TABLE 7.—BLOOD AND RESPIRATION IN CASE 6

	Before Transfusion	After Transfusion
Red blood cells	1,288,000	3,192,000
Hemoglobin, per cent.	30	60
Respiration	28-40	20
Pulse	96-108	80-88
Cell volume, per cent.	7	19

The cell volume of the donor was 49 per cent.

Blood volume = 2,623 + 66 c.c. = 2,689 c.c.

The patient improved promptly, and gained in strength and appetite. The cough ceased, and a few days later she went about the wards. She left the hospital two weeks after transfusion. Her condition was good.

CASE 7.—A man, aged 58, weighing 150 pounds, and 5 feet 8 inches in height, had been ill with the disease one year. The teeth were in poor condition. This is the type of case I regard as unfavorable. The reasons for this will be discussed in some of my subsequent papers. We have not succeeded as yet in persuading the patient to have the mouth roentgenographed and treated.

The first transfusion, of 2,300 c.c., was performed, Sept. 5, 1917. There was no chill. There was a rise in temperature of 3 degrees. The second transfusion, of 1,500 c.c., was performed, Nov. 14, 1917. There was no chill. There was a rise in temperature of 2 degrees.

The third transfusion, of 1,200 c.c., was performed, Jan. 17, 1918. There was no chill. There was a rise in temperature of 3 degrees. Before the third transfusion, 70 c.c. of blood were withdrawn. Before this transfusion, the patient was very pale, there was palpitation of the heart, and there were roaring and a thumping noise in the ears. He was able to walk about the house, and up and down stairs, though he was weak. His appetite was fair.

TABLE 8.—BLOOD AND RESPIRATION IN CASE 7

	Before Transfusion	After Transfusion
Red blood cells	1,100,000	2,800,000
Hemoglobin, per cent.	25	60
Respiration	22	20
Pulse	76	72
Cell volume, per cent.	12.58	23.29

The cell volume of the donor was 48.88 per cent.

Blood volume = 2,868 c.c. + 70 c.c. = 2,938 c.c. = 4.08 per cent., or two forty-ninths of the body weight.

The usual improvement following transfusion was delayed in this case until the fourth day. The appetite was increased, and there was a return of strength with disappearance of the symptoms.

The symptoms should be compared with those in the same degree of anemia in Cases 1, 2 and 3.

The patient has remained in good condition since his last transfusion.

March 22, I was informed that there had been general moderate edema in the past few days, with hemoglobin, 38 per cent.

CASE 8.—A man, aged 66, weighing 180 pounds, and 6 feet in height, had been ill with the disease two and one-half years. Before consulting me in May, 1916, he had received a series of small transfusions at home of 500 c.c. each, over a period of about four months, with only slight temporary benefit.

I performed the first transfusion, of 1,600 c.c., May 2, 1916. There was no chill nor fever.

May 4, 1916, splenectomy was performed. He remained well one year, when he again returned for transfusion.

May 13, 1917, the patient received 2,300 c.c. There was no chill. There was a rise in temperature of 2 degrees. He went home, a distance of 150 miles, two days later.

Convinced of the benefit of large transfusions, he came to New York, Dec. 6, 1917, for a transfusion. He received 1,500 c.c., with no chill and no rise of temperature, and returned to his home twenty-four hours later. The symptoms before transfusion were loss of appetite, moderate weakness, a slight ringing and a thumping noise in the ears, and "fluttering of the heart."

TABLE 9.—THE BLOOD IN CASE 8

	Before Transfusion	After Transfusion
Red blood cells	1,250,000	2,800,000
Hemoglobin, per cent.	30	60
Blood Pressure—		
Systolic	130	145
Diastolic	90	95
Cell volume, per cent.	13.5	24.1

The cell volume of the donor was 48.6 per cent.

Blood volume = 3,207 c.c. + 8 c.c. = 3,215 c.c. = 4.94 per cent., or one twentieth of the body weight.

The transfusion was followed by a rapid disappearance of all the symptoms and a return of the appetite.

It should be noted that this man, with an anemia of 1,250,000, and 30 per cent. hemoglobin, was capable of traveling 150 miles to New York without any distress. This would not have been possible if the volume of the blood had not been adequate as in Cases 1, 2 and 3, even though the degree of anemia was the same.

CASE 9.—A woman, aged 67, weighing 160 pounds, and 5 feet 9 inches in height, had been ill with the disease one and one-fourth years. An interesting fact to note in conjunction with this case is that the daughter during the past twenty years has also had no free hydrochloric acid in her stomach; she is now 43 years old, and as yet shows no evidence of the disease.

The first transfusion, of 1,400 c.c., was performed, July 2, 1917. There was no chill nor fever.

The second transfusion, of 1,600 c.c., was performed, Nov. 17, 1917. There was no chill. There was a rise in temperature of 4 degrees.

The third transfusion, of 1,520 c.c., was performed, Feb. 11, 1918. There was no chill. There was a rise in temperature of 2 degrees.

Before the third transfusion this patient was in fairly good general condition excepting for loss of appetite and weakness. Her weakness was due chiefly to lesions of the spinal cord (partial paralysis), which was involved at the onset of her disease. Her first symptoms were those referred to these lesions, and they have persisted and gradually increased since. There was no dyspnea, prostration, palpitation, or noises in the ears.

TABLE 10.—BLOOD AND RESPIRATION IN CASE 9

	Before Transfusion	After Transfusion
Red blood cells	1,440,000	2,900,000
Hemoglobin, per cent.	30	50
Respiration	20	20
Pulse	72	72
Blood Pressure—		
Systolic	130	140
Diastolic	90	95
Cell volume, per cent.	15.19	27.11

The cell volume of the donor was 45.76 per cent.; the amount transfused, 1,520 c.c.; 75 c.c. of blood were removed before transfusion.

Blood volume = 4,130 c.c. + 75 c.c. = 4,205 c.c. = 5.4 per cent., or one eighteenth of the body weight.

After the transfusion, the patient's appetite returned, and her general condition, except that associated with the cord involvement, improved.

The absence of many symptoms in this case, except those referred to the cord compared with other cases of the same degree of anemia but lesser blood volume, should be noted.

CASE 10.—A man, aged 60, weighing 165 pounds, and 5 feet 9 inches in height, had been ill with the disease six years. The teeth were in good condition. Roentgenoscopy of the teeth was negative. The patient had been through several remissions of the disease, and responded well to arsenic at each crisis. Finally, in the last crisis, he failed to respond to any form of medication or treatment. It was then decided to employ transfusion.

The chief symptom before transfusion was drowsiness. There was moderate weakness; no palpitation of the heart, and no ear noises. The amount transfused was 1,510 c.c.; 65 c.c. were withdrawn before transfusion.

TABLE 11.—BLOOD AND RESPIRATION IN CASE 10

	Before Transfusion	After Transfusion
Red blood cells	1,330,000	2,900,000
Hemoglobin, per cent.	26	45
Respiration	20	20
Pulse	68	68
Cell volume, per cent.	14.75	22.2
Blood Pressure—		
Systolic	136	145
Diastolic	90	95

The cell volume of the donor was 42.6 per cent.

Blood volume = 4,134 c.c. + 65 c.c. = 4,199 c.c. = 5.29 per cent., or one eighteenth of the body weight.

After the transfusion, there was return of appetite and strength.

The absence of many symptoms in this case that are present in other cases of anemia of the same degree but of lesser blood volume may be noted.

COMMENT

[illegible] the preliminary report I mentioned the fact that blood [illegible] counts give results that are inaccurate and of 140 and valueless in the estimation of blood volume.

I do not mean to convey the idea that it is only necessary to correct the blood volume in order to effect a cure. My studies indicate that the blood volume in pernicious anemia is always reduced—that when the reduction in volume is only slight, the symptoms other than those referred to the nervous system, even though the degree of anemia may be severe, are relatively fewer and milder, and are borne with less distress. As the volume of blood is reduced, the symptoms of the disease increase proportionally. It is imperative, therefore, that to give proper treatment, an effort should be made to increase the bulk. The two ways in which this is best accomplished are by (1) an abundant fluid diet, preferably 2 quarts of milk a day, and (2) blood transfusion.

Diarrhea must be avoided because it reduces blood volume. Should it occur it should be regarded seriously and relieved promptly.

Patients should be given an abundance of milk in addition to the other forms of dietary regimen that may be employed. Even though the patient has aversion to all forms of food, milk should be forced. I am sure it will be found that many patients will bear their disease better and will be better able to await the favorable moment for improvement. In a great many cases, however, the blood regenerative power is extremely low and incapable of stimulation by the usual methods. These patients grow worse even with a relatively high blood volume. A large volume and a rich blood mixture are imperative in order to improve the desire and ability to take food and to restore the patients to a nearly normal condition. The only thing capable of doing this promptly and effectively is transfusion of unmodified blood in large amounts. It is a life saving measure. No other therapeutic procedure has so much value in robbing the disease of its terrors.

I have a large series of patients in whom transfusion has been performed with small amounts; but the large quantities yield very much better results.

It is seen that in this series of patients with pernicious anemia the blood volume varies from 1,600 to 4,200 c.c., or from 2.4 to 5 per cent. of the body weight. Those with the lowest figures are not ambulatory patients, and they suffer greatly with the disease. The patients with the higher figures, except in Case 9, could go about their homes and attend to their personal wants, and are in relatively better condition.

The normal blood volume in man, according to Keith, Rowntree and Geraghty, is 9 per cent. According to Haldane and Smith it is about 5 per cent. From my studies on donors when large quantities of blood have been drawn for transfusion, I am inclined to believe that the former workers are more nearly correct.

One should guard against extravagant claims as to curing the disease, because of its tendency to recur even after many years. Recently I was consulted in a case that had recurred after seventeen years.

The cases cited above are undoubted cases of pernicious anemia. They are not selected, but comprise a complete group of patients who have presented themselves to me during the interim of these blood volume studies. I have several cases of apparent cure, but I do not know when the disease may recur. I think that from the new studies now being made, and the new instrumentalities and procedures available, so much can be done in pernicious anemia that it may yet be possible to effect a cure in some cases.

The transfusions were all performed by the syringe cannula system[2] without recourse to saline, citrate of soda or any other foreign material. Lindeman cannulas are painlessly inserted into the veins without skin incision and with record syringes 20 c.c. capacity blood is rapidly transfused from donor to patient. The work is done in such manner that the entire blood mass, regardless of the amount transfused, is outside the body for a period of only 6 to 10 seconds. This is well within the time limits of any possible chemical or physical change of the blood transfused. Reactions are thus eliminated.

565 Park Avenue.

Clinical Notes, Suggestions, and New Instruments

AN INSTRUCTIVE CASE OF PROSTATIC ADENOMAS WITH VESICAL CALCULUS CONCEALED BY A SESSILE PEDUNCULATED MEDIAN LOBE

G. Frank Lydston, M.D., Chicago

The case herewith presented has several instructive features from the peculiar arrangement of the prostatic overgrowth. The impossibility of diagnosing the calculus on account of its concealment by a broad sessile pedunculated tumor originating in the posterior median portion of the prostate is unique.

A man, aged 69, a merchant, had always enjoyed unusually good health until the development of vesical symptoms about six years before consulting me. The urine had remained normal in appearance and apparently had not been infected, despite several attacks of retention, which had occurred during the past year and had been relieved by the catheter. Micturition became very frequent, and the disturbance of rest at night had compelled the patient to seek relief.

Examination revealed a large, diffuse, prostatic tumor. This was moderately firm and only slightly sensitive. Cystoscopy revealed a trabeculated bladder and a large median prostatic tumor. The bladder mucosa was in remarkably good condition, considering the attacks of retention and the catheterization necessary for relief. The kidneys apparently were in good condition and the case an ideal one for operation.

I performed a perineal prostatectomy, the operation proving exceptionally easy of performance. Thirteen adenomas of various sizes and shapes were shelled out from the lateral lobes. Digital exploration of the bladder revealed a large, flattened tumor, which fell directly down curtainwise from the lower segment of the vesical orifice. The attachment of this tumor was so tenuous that it may be described as "membranous," the tumor being readily detached by being wiped off, so to speak, from the sublying tissues. Beneath the tumor was found a phosphatic calculus, which was so completely concealed by the overhanging growth that it could not be felt with the exploring finger until the tumor was detached. That cystoscopy or instrumental exploration of the bladder should fail to detect a stone located as in this case is not at all remarkable. The distal surface of the median tumor, which concealed the stone, showed a concavity that perfectly fitted the calculus. It is obvious that this arrangement saved the patient considerable annoyance from the presence of the foreign body. The operation occupied only twelve minutes, the tumor being shelled out with great facility.

The patient left the hospital on the fourteenth day, at which time he was passing urine naturally. At last accounts, two years after operation, the patient was perfectly well.

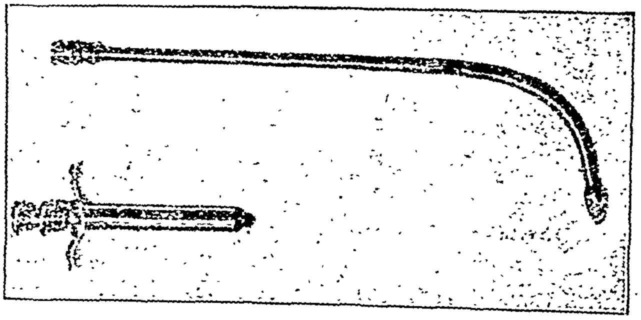
A MODIFICATION OF ULTZMANN'S SYRINGE FOR POSTERIOR URETHRAL INSTILLATIONS

Frank Hinman, M.D., San Francisco

The proper instillation of solutions into the posterior urethra has a well recognized value in the treatment of many of its chronic inflammatory conditions. The particular object in view is to insert the end of the instrument just beyond the external sphincter. The colliculus should not be touched or reached. It has been shown experimentally in animals that stimulations of a healthy urethra will not produce an antiperistaltic wave, whereas, almost invariably, stimulation of an inflamed colliculus produces antiperistalsis of the vas deferens, which, if we argue from analogy, in men would frequently carry infective material to the globus minor of the epididymis.

The instruments introduced for giving these posterior urethral instillations have been quite numerous. The two types most frequently in use are the Ultzmann cannula, and the Guyon elastic catheter. The latter has the great advantage, because of the bulb at the end, that it can be more accurately placed to a point just inside the external sphincter without any great risk of irritating the colliculus; but it has the disadvantage of not being easily sterilized and, when a great many treatments have to be given, the catheters quickly wear out or become rough and irritating to the urethra. In certain patients with tight sphincters, furthermore, catheters, if at all limber, are difficult to insert.



Metal urethral cannula with bulb: an all metal syringe for urethral instillations.

The Keyes-Ultzmann instrument is a silver cannula of even caliber which has a glass barrel syringe with a metal piston. The original Ultzmann used a record type of syringe, and this could be readily boiled for sterilization; but in frequent boiling the glass barrels of the syringes are often broken, and the absence of a bulbous end makes it more difficult of accurate insertion.

Bumstead introduced a hard rubber cannula, and his instrument was modified by Taylor with the addition of a bulb, as in Guyon's catheter. With the Taylor-Bumstead cannula a glass-barrel syringe was also used. Dick introduced his silver catheter syringe, which, however, must be inserted to the level of the colliculus on account of the multiple perforations at its end.

In the accompanying illustration, an Ultzmann silver cannula is shown on which has been soldered a No. 16 bulb from a metal bougie à boule. The bulb has been tunneled so as to connect with the lumen of the cannula. This allows the cannula to be inserted into the urethra with the same accuracy that can be obtained with Guyon's elastic bulb catheter, and with greater ease, because it is a stiff instrument. The syringe used is an all metal one of the military type which can be firmly screwed to the end of the cannula, making a one piece instrument. This can be boiled and reboiled without injury or wear. It fulfils, therefore, the demands of practical utility, as well as sterilization. Several of these modifications have been in use for over two years at the University of California Urologic Clinic and are apparently still in as good condition as at the beginning.

SOME FEATURES OF MAMMARY GLAND FUNCTIONS

Precisely how the mammary gland elaborates the products that characterize milk as a unique secretion has long been a serious problem of physiology. Much of the interest has centered in the fat of milk, for this foodstuff is readily deposited in various parts of the body and is seemingly also mobilized readily and transported by the circulation to other organs and tissues. With reference to milk production the question has often been raised as to whether fat is taken up by the mammary glands from the blood and eliminated with their secretion, or whether the milk fat is produced within the cell protoplasm, whence it is set free as the suspended globules of milk.

These inquiries permit a new formulation in the light of the more recent studies on the assimilation and metabolism of fats in the body. The investigations of Bloor in particular have indicated an unexpected participation of the blood lipoids, cholesterol and lecithin, in the transformations and transport of ingested fats. Bloor's studies lead to the conclusion that the blood corpuscles take up the fat from the plasma and convert it into lecithin. As most if not all absorbed fat seems to be so transformed, it seems more than likely that lecithin is an intermediate step — perhaps the first stage—in the metabolism of the fats. It has even been suggested[1] that the peculiar anatomic arrangement whereby the fats are thrown into the circulation through the thoracic duct and thoroughly mixed with blood in the heart and lungs before they reach any of the organs of intermediate metabolism, like the liver, may be attributable to the need for conversion into lipoid compounds. If the first step takes place in the blood corpuscles, it is to be expected, says Bloor, that they will be given an opportunity to take up as much of the fat as possible before it comes into contact with the organs and tissues. He adds that it is quite unlikely that lecithin formation is limited to the blood cells. Many types of fixed cells may play a similar part.

In the light of these considerations, a new interest attaches to the phosphorus metabolism of the mammary gland in relation to the secretion of milk fat. The lipoid lecithin, it will be recalled, contains phosphorus. At the Bureau of Animal Industry in Washington, Meigs and Blatherwick[2] have made analyses of blood samples obtained nearly simultaneously from the jugular and mammary veins of milking cows. The plasma was analyzed with the object of determining whether the concentrations of total, lipoid and inorganic phosphorus were appreciably altered during the passage of the blood through the active gland. Under suitable experimental conditions, the mammary plasma had a lower concentration of lipoid phosphorus and a higher concentration of inorganic phosphorus than the jugular. These results are taken to mean that the precursor in plasma of both milk fat and milk phosphorus is either lecithin or some related compound. The ratio of phosphorus to fat in lecithin is about 1 : 18, whereas it is about 1 : 50 in milk. The government dairy chemists argue, therefore, that if the mammary gland takes from the plasma enough lecithin or enough of some related phosphatid body to supply its milk with fat, it gets with it more phosphorus than can be used for the milk, and the excess must be returned to the blood. These considerations are taken to explain the backflow of inorganic phosphorus from the mammary gland to the blood, which occurred in all the experiments. The prospect of new and important contributions to the genesis of the fats and other components of milk thus looms up.

PROTEIN HYPERSENSITIVENESS AND THE KIDNEYS

The time has long since passed when a variety of cutaneous disturbances, such as erythemas and urticarias, were assumed to be essentially local or skin manifestations. The attempt to manage some of them as if they were merely the indexes of abnormalities due to the peripheral nervous mechanisms has likewise not been advantageous from a therapeutic standpoint. On the other hand, the demonstration that recurring attacks of purpura, angioneurotic edema, erythema and urticaria may be associated with changes in the internal viscera[3] has helped, among other considerations, to emphasize the manifold and perhaps generalized character of the underlying pathogenic factors.

Since some of the pronounced reactions of the skin and mucous membranes — even chronic eczema and asthmatic attacks — have of late been assigned an anaphylactic etiology in part at least, and since hypersensitiveness to certain proteins has clearly been demonstrated in numerous carefully observed cases, the question of the extent to which various other tissues may also be involved naturally arises. In other words, if the skin, the respiratory tract, and the gastro-intestinal canal may be the seat of phenomena of hypersensitiveness to foreign proteins, what other organs may also be involved?

In the case of the kidneys, which are already believed to participate at times in the disturbances of experimental anaphylactic shock, the evidence ought to be obtainable in clinical cases without great difficulties; for the methods of evaluating renal function have been developed with much success in recent times. At the Medical Clinic of the Presbyterian Hospital, New York, the observations of Longcope and Rackemann,[4] on a very limited number of persons demonstrably hypersensitive to foreign proteins, have shown albuminuria, cylindruria, increase in blood urea, profound depression of the index of urea excretion, decrease in the output of phenolsulphonephthalein, and retention of chlorids and water during attacks of urticaria and erythema. It is conceivable that infections which so frequently leave kidney impairment may bring about their results by a somewhat comparable response to foreign bacterial protein. As Longcope and Rackemann visualize the possibility, the reaction in the kidney might be closely analogous to the cutaneous reactions. The peculiar inflammation of the renal structures might accordingly be dependent on an altered reaction or allergy of these structures toward the soluble protein products of bacterial origin or to the proteins of the bacterial bodies themselves. Whether the intoxication causes a general disturbance in protein metabolism in addition to the renal injury remains to be clearly demonstrated.

STARCH DIGESTION IN EARLY LIFE

Current ideas regarding the ability of the organism of the very young to digest starch have undergone considerable change in recent years. The supposed failure to detect starch-digesting enzymes in the saliva of the new-born was presumably responsible for the conclusion that the body possesses no mechanism for converting starch into absorbable derivatives at an early age. On such a deduction obviously rests the decision as to whether starch in any form can properly be included in the food of this period of life; in other words, the problem of the time when cereal feeding may become a physiologic propriety is here involved.

Careful examination of the saliva of the very young has, however, shown that amylase is by no means always entirely lacking; but even if it were, the possibilities for the digestive utilization of starch are not limited to the efficiency of the saliva. Beside the salivary glands, other structures, notably the pancreas, are sources of starch-digesting enzymes that need to be reckoned with. Certain animals, like the dog and cat, do not possess any salivary amylase at any age; yet they can utilize starch in considerable measure.

Obviously a more adequate method of judging the starch-digesting capacity of the very young consists in examining the feces for unutilized starch after this foodstuff has been fed. Long ago the Berlin pediatrician Heubner[1] reported the outcome of such studies in the case of children a few weeks old. Among others in this country Kerley, Campbell and Mason[2] reported in The Journal the results of an examination for starch of 324 stools collected under controlled conditions at the New York Infant Asylum from sixty children, all under 1 year of age, who had been fed either wholly or in part on barley water. More than half of these children always showed negative tests indicating complete utilization of the starch thus fed.

Details of such findings might easily be duplicated now in considerable number. In view of the fact that many of the views regarding the question here at issue have been derived by analogy from experimental observations on embryonic and new-born animals, it is not without interest to follow some of the later developments in the domain of comparative physiology. In a once widely quoted monograph on the digestive enzymes of the embryo and the new-born, Krüger[3] reported that in fetal and new-born calves ptyalin is secreted in the salivary glands as early as the seventh month of fetal life, but that while the quantity increases up to birth, even at that time it is too small to be of any importance in the digestion of food. The latest data from the Dairy Division of the Bureau of Animal Industry in Washington[4] show that calves from 4 to 7 days old are able to digest considerable cornstarch added to their milk ration. The capacity seems to increase so that at the age of 3 or 4 weeks more than 90 per cent. of a liberal starch intake may be digested. The dairy chemists who conducted these studies conclude that while it is quite probable that a calf only a few hours old cannot digest an appreciable amount of starch, it can readily be seen that the quantity of starch-splitting enzymes must increase very rapidly in the first few days of life, for the calves under experiment, when only 3 or 4 weeks old, were able to digest a ration, nearly 10 per cent. of the dry matter of which was starch.

The attempt to ascertain the digestive capacities of the young is not to be construed as advice to use starchy foods at any definite age in infant feeding. Whatever will help us to forecast the possibilities of digestion in early life is likely to facilitate rational procedures where dietary intervention becomes necessary.

A MAINTENANCE DIET FOR DIABETICS

In the modern treatment of diabetes by a rigorous dietary regimen, the difficulties presented in certain cases by the necessity of reduction of the intake of all types of foodstuffs often offer a most perplexing problem to the practitioner. When the "strict" diet involving merely the complete omission of all forms of carbohydrate came into vogue, the difficulties seemed to be avertible by an increase in the allowance of protein and fat so that the total calory intake would still be abundant. The foremost aim of many therapeutists seemed to be to conserve the weight of the patient quite as much as to stop the elimination of unburned sugar. But it is recognized today that in a severe case of diabetes not only sugar but also protein and fat may be incompletely oxidized by the organism.

To avoid the always unfavorable production of undesirable intermediary products that thus result, it often becomes necessary to restrict the food intake to a level within the metabolic capacity of the person under consideration. Starvation presents one very effective method of accomplishing such a result, but obviously it cannot be persisted in for any considerable period. One result of the systematic and radical reduction in the food of diabetics—a procedure made practicable in many ways through the investigations of Allen—is the inevitable reduction in the body size of the patient. The fact is often overlooked that when a person has been reduced in weight, his metabolism when he is fed on a low dietary will also be reduced. This may bring his organism within the range of metabolic performances that would not have sufficed for the larger stage of nutrition.

Mosenthal and Clausen[1] have recently pointed out that the widespread use of very limited diets in diabetes has brought up the question of how little the individual may eat and still remain physically and mentally fit. As they rightly point out, the maintenance diet, under ideal conditions, should be sufficiently high not only to enable the patient to live, but also to carry on an average amount of physical and mental work without undue fatigue. The nitrogen equilibrium, they add, represents the lowest possible diet standard that can be exacted of any patient who is to be maintained in a condition of reasonable well-being for any considerable period. To quote Mosenthal and Clausen in their fundamental contention, food which still permits nitrogen equilibrium under these circumstances results in the conservation of the protein tissues, but does not necessarily prevent the loss of fat. This principle has been applied in the treatment of obesity. No living being can afford to lose muscle and glandular tissue indefinitely. How far the fat store of any individual may be depleted with advantage is another question. There is much to be said in favor of allowing the diabetic to become thin, so that his metabolism may be established at a lower level, as has frequently been urged; but it should be distinctly appreciated that this loss of weight should occur in the fats and not in the vitally necessary proteins.

Contrary to what may have been anticipated, these investigators at the Johns Hopkins Medical Clinic have observed that a diabetic may often not only conserve but even amass body protein while on a practically carbohydrate-free diet. According to them, furthermore, diabetic patients may be established in nitrogen equilibrium by a carbohydrate-free diet having a caloric value equal to the standard total caloric requirement. In many instances this may be accomplished at a considerably lower level of feeding. The factors that determine the dietary level at which a diabetic attains a nitrogen balance are apparently very numerous, and not fully determined; glycosuria at times, and infections, even of very slight degree, may necessitate a higher diet to bring about the desired result. A rough estimate of what constitutes a maintenance ration for the diabetic on a carbohydrate-free diet is placed by Mosenthal and Clausen at between 1,500 and 2,000 calories, with the reminder that women and small persons generally require less food than men and larger persons.

Current Comment

WHERE NEGATION IS A VIRTUE

It is the practice of newspapers and other publications to advertise their own advertising preeminence. Naturally such advertisements usually emphasize the large amount of advertising patronage the papers have enjoyed during a given period, and comparison is frequently made with the amount of advertising carried by competitors. The Chicago *Tribune* this week, in an advertisement three columns wide and seventeen inches high, directs the attention of advertisers in general to the desirability of the *Tribune* as an advertising medium. It points out that during the past year it has led all other Chicago papers "in the advertising of automobiles, clothing, groceries, financial, real estate, musical instruments, furniture, publishers, hotels and resorts, educational and other classifications." Thus far there is nothing unusual in the advertisement. The balance of the advertisement, however, emphasizes the fact that, although the Chicago *Tribune* was *first* in the list of advertising commodities just named, it "was *fourth* in medical advertising." The Journal has not infrequently expressed its opinion of quack and nostrum advertising. All it has ever published and all it may ever publish will never show more effectively than does this *Tribune* advertisement, the generally undesirable character of the "patent medicine" business and quackery. A high class newspaper emphasizes the desirability of its pages for the advertising of meritorious products and takes pride in the fact that it accepts less medical advertising than certain of its competitors! To attempt to add to this indictment would be to gild refined gold and paint the lily.

SUGAR REAGENTS

One of the most frequently employed chemical tests by the physician is the "sugar test"—Fehling's, Haines', Benedict's, etc.—whereby a copper solution is reduced by a sugar, forming a precipitate of copper oxid which is generally red. These tests, however, often yield indecisive colors, leading to doubtful clinical interpretations. In testing urine of diabetics, for example, sometimes the reduction causes the formation of a precipitate not red, but orange, yellow, or even greenish. A number of years ago, McLean[1] surmised that these differences were merely physical. More recently two Cincinnati workers[2] have confirmed McLean's views, although at the time of the research, they were unaware of the previous work. Contrary to the impression given by many textbooks, these authors state that in testing urine with Fehling's solution "a dirty pea green solution means just as much from a qualitative point of view as does a red precipitate." The causes for the variations in the tests are such factors as relative degree of concentration, presence of such substances as will have a stabilizing effect (protective colloids), and temperature. After a series of experiments, they concluded that "the different colors observed in the reduction of Fehling's solution by dextrose (or other reducing substance) are nothing more than color changes coincident with a gradual increase in the size of the copper oxid particles." In connection with the foregoing discussion on Fehling's and modified solutions, it is interesting to note that Folin and McEllroy[3] have proposed a copper-phosphate mixture as a sugar reagent, which they claim has several advantages. The alkaline phosphates are less expensive than the tartrates, citrates or glycerin used in other reagents; they do not themselves reduce sugar; and they tend to regulate the degree of alkalinity at a lower level of hydroxyl ion concentration than is obtained by carbonates alone. The copper-phosphate[4] mixture for qualitative determinations is used eactly as Benedict's reagent for sugar, and is of the same degree of reliability but a trifle more prompt. For the quantitative determination of sugar in urine or lactose in milk[5] a somewhat similar copper-phosphate mixture proved very satisfactory.

THE RESPONSE TO THE CALL FOR MEDICAL OFFICERS

A few weeks ago we published the letter of the Surgeon-General asking the American Medical Association to secure 5,000 additional medical reserve officers; also the announcement that the War Committee of the American Medical Association had arranged to call into conference the secretaries of the constituent state associations in order to outline an efficient method for securing the necessary men. The physician who reads the report of this conference in this issue of The Journal[1] will realize that the American Medical Association is answering this call with an energy and a utilization of its resources which cannot fail to produce the desired increment. As the secretaries of the state associations outlined the work thus far done in their respective states and pointed out the defects of the system which, although it has produced to date 22,000 physicians, has nevertheless permitted many defects, it became apparent that the task before the profession is important not only in securing physicians to meet the present demand, but for the future, whatever it may be. In securing over 20,000 volunteers some communities may be suffering through the taking away of men needed in those communities. Some industrial plants may be suffering through the removal of physicians whose duties in caring for the health of thousands of industrial workers were at least as important as any task which they might undertake in connection with the military department. The organization of the state for war means the utilization of every man to the best possible advantage. The secretaries of the state associations were firm in their belief that they would be able to secure the men needed for the new increment. Their conference was especially important with a view to meeting the future needs of the country, whether the war lasts one year or five years or ten years.

Banana as Food.—In an article in the *Scientific Monthly* (January, 1918) Prof. Samuel C. Prescott of the Massachusetts Institute of Technology says that the banana is a high power fuel food and is also rich in desirable salts. He quotes the table of Bulletin 28 of the United States Department of Agriculture showing the caloric value per pound of the edible portion of the banana and other foods, from which the following comparisons may be selected: banana, 460; squash, 215; onions, 225; parsnips, 300; green peas, 465; cabbage, 145; green corn, 470; fresh Lima beans, 570; macaroni, cooked, 415; string beans, 95; clams, 240; lobster, 390; oysters, 230; halibut, 470; whole milk, 325; apples, 290; cherries, 365; figs, 380; grapes, 450; oranges, 240. It will thus be seen, as Professor Prescott says, that the banana exceeds in real food value many foods of different classes which are in almost daily use, such as whole milk, boiled oatmeal, shellfish and other fish and fresh vegetables, and according to a bulletin of the Life Extension Institute, prepared by Dr. Eugene Lyman Fisk, presenting a table of raw materials in common use, it is the cheapest. In concluding his article Professor Prescott says that the banana is practically the only food which during the last two years has not shown a marked increase in price, and will stand comparison with any food on the market on the basis of caloric costs. Everything, he says, points to its continued favor not merely as the "poor man's fruit," as it has sometimes been called, but as a staple food for universal use.

Association News

WAR CONFERENCE OF SECRETARIES OF THE CONSTITUENT STATE ASSOCIATIONS OF THE AMERICAN MEDICAL ASSOCIATION

Held at the Headquarters of the American Medical Association, April 30, 1918

The meeting was called to order by Dr. Alexander R. Craig, secretary of the American Medical Association. Dr. Thomas McDavitt of St. Paul, chairman of the Board of Trustees, was elected chairman, and Dr. A. R. Craig, secretary.

Dr. McDavitt emphasized the great importance of the meeting. He said the government had made a new call for physicians. There are already in the service, in the different corps, at the present time about 20,000 physicians. The issues involved are so great that the government is anxious to have an excess if possible. The 5,000 physicians that are requested now do not provide for an excess. The ways and means of filling these ranks will depend largely on the successful issue of the action taken by this conference.

The roll of the states was called, and the following secretaries answered as being present:

Alabama—H. G. Perry
Arizona—D. F. Harbridge, acting
Arkansas—C. P. Meriwether
Colorado—Crum Epler
Connecticut—J. E. Lane
Dist. of Columbia—H. C. Macatee
Illinois—W. H. Gilmore
Indiana—Chas. N. Combs
Iowa—T. B. Throckmorton
Kansas—L. F. Barney, acting
Kentucky—P. E. Blackerby, special
Louisiana—Paul T. Talbot
Maine—Bertram L. Bryant, acting
Michigan—F. C. Warnshuis
Minnesota—Thomas McDavitt
Mississippi—T. M. Dye, acting

WORK OF THE WAR COMMITTEE OF THE ASSOCIATION

The chairman introduced Dr. Simmons, who, he said, had been in close touch with the government authorities and would give information on the subject of the conference.

Dr. Simmons said that we are today confronted with what some regard as a serious proposition but that he did not so regard it. He has always felt that the medical profession would respond to whatever call was made on it, and that the response has been made. Practically 23,000 physicians volunteered for the Medical Reserve Corps. On April 26, 18,693 had accepted commissions. We may estimate that at least between 1,000 and 1,500 will be added to this number from those who have already been offered commissions. At the beginning of the war there were 449 medical officers in the regular corps. Today there are 20,851 in the service; in the regular corps, 843; in the reserve corps, 18,693; in the National Guard, 1,204; in the National Army, 111.

When the call was first made it was for 21,000 physicians, estimated on the basis of an army of 3,000,000. There are supposed to be seven medical officers per thousand; it is recognized that this is not enough and they estimate now ten men to a thousand.

WORK OF THE ASSOCIATION

It might be well for a moment to say what the American Medical Association has done. In April, 1917, THE JOURNAL began to appeal to the medical profession. In that month we published a special appeal and with it an application blank—64,000 blanks—for both the Regular and Medical Reserve Corps. Four weeks later an application blank—67,000 this time—was again inserted in THE JOURNAL.

The next work done was that done ostensibly by the Surgeon-General, who assigned to our office Major J. R. McKnight, who is present this morning. I have here the report that Major McKnight made to the Surgeon-General, July 19. The work was begun May 28, and this report covers the work up to July 16. At that time the total number of circulars addressed was 39,710; the reply cards received were 17,874; requests for information answered by personal letter, 764. This final analysis of this work, I am sorry to say, is not at hand. Analysis of the cards received show that 2,786 immediately applied for commission; 1,781 stated that they would reply soon, and 1,990 that they would apply within a few weeks. Various reasons were given for not applying, such as physical disqualifications, dependents, etc. This work was done, as I say, ostensibly by the Surgeon-General's Office, in so far as Major McKnight superintended it; but the Association furnished the material and did all the printing; everything was sent out from this office—the application, letters of appeal, information for those who responded as to what to do, the list of examining boards, etc.

THE NEW CALL

Now this drive, if I may call it so, because that is what it is going to be, is to be done in the name of and by the American Medical Association and its constituent associations. The responsibility is on us to make good.

Dr. M. L. Harris said that the Association, through the Board of Trustees, has been called on by the Surgeon-General to assist. A special meeting was called and a committee appointed to look after this work directly, which for want of a better name was called the war committee. This committee has been in touch with Washington ever since its appointment, and has attempted to help the department by placing at its disposal the entire American Medical Association and all its machinery, including, of course, THE JOURNAL, which as you know already had been doing what it could from the beginning.

Now that we have been requested to assume this further task of enlisting 5,000 additional doctors for the Army and to secure this number in a short time, this meeting was called to distribute the burden down to the individual unit; in other words, those who are most familiar with local conditions, so that this could be done with the least harm, we may say, to local communities and with the greatest dispatch. The idea is to get the doctors where they are most available and where their withdrawal would mean the least trouble in properly taking care of civil conditions. Not only the general population, but industries must be considered; in fact, all the factors that are essential to the organization and maintenance of the Army.

The purpose of this meeting is for all of us to discuss the matter and to suggest means. The general idea which may be presented, of course for your approval or modification and ratification, is that in addition to what we may call the national war board, that is, the committee of the Association representing the Board of Trustees, each state society have its state war committee represented by its officers, and that each county have a county war committee, the committees to be small in number so that they may work rapidly and expeditiously, the idea being that each county naturally is most familiar with its own local conditions and can best determine who is most eligible for the service in the sense of the needs of the community. In the same way the state as a whole is more familiar with general conditions and can work out its own problems better than any one else. It is hoped that by the organization of these committees the work could be carried out with dispatch and with the best results, having in mind the needs of local conditions and the needs of the Army.

The chairman introduced Dr. Charles Mayo, President of the Association. Dr. Mayo said that this is really to be a drive like a liberty loan drive, as Dr. Simmons says. The medical profession was almost the first to become well organized before the war began, because we have had an organization for a long time. So far as the Association is concerned, it was easy for organized medicine to get the names of the men we needed to do their bit. In fact, they had been doing their bit by going over to help Britain, France and Serbia in every possible way.

DISORGANIZATION

Our profession is organized, but around the outskirts is a great deal of disorganization that has been held over from the methods of the profession in advancing their work in education. In the early period there were in Washington about eighteen bureaus, boards and departments that had to do with medicine. Each of these bureaus and departments spends a great deal of money, and there is absolutely no coordination and no one will let go. Each head wants to be chairman of the committee to look after it. The more we study the question, the more we find that there will be no change until we get a real department of health with an officer in the cabinet to look after it, and then we will have an organization.

CONDITIONS IN FRANCE

A serious problem comes to mind in relation to France. There they have not had any medical schools running for four years. In England the same thing is true. With the natural death rate of doctors and no new degrees granted, it means a great deduction, and the danger that when the schools have started again, there will be lowered standards. I think organized medicine in this country did great service in seeing to it that the government did not in developing draft laws break up the medical schools. I think that has been one of the greatest features shown by organized medicine.

A FRENCH MEDICAL SCHOOL

The thing I have been hoping for is that funds may be obtained to develop a great medical teaching institution in Paris. From letters received from the French government, the president and others high in authority, this idea is approved. We could move our men over there a thousand at a time and they could be trained by men at the front who for four years have had at their fingers' ends things that we cannot possibly get in this country. I would suggest to turn over now for teaching purposes two thirds to the Americans and one third to France, and after the war make France a present of it, and make Paris the center for American medical study in Europe. It takes a lot of money to run such an institution, but yet it looks as though the money might be raised. It is estimated that it would take from $100,000 to $150,000 under present circumstances to run such a school for a year. It is most difficult to bring about such a thing under government control. Something like that must be planned by organized medicine, but not by government organized medicine, and turned over to the Surgeon-General for the period of the war. Surgeon-General Gorgas could easily detail men in the service for temporary duty for the education of these men and give them one month or two months of lectures, and without disorganization we could give our surgeons the absolutely necessary instruction and all around service we have been trying to develop in a more or less haphazard way.

The chairman introduced Dr. Alexander R. Craig, secretary of the American Medical Association. Dr. Craig said: It may be well for me to try to supplement what has been said of the work of the Association with your cooperation. Lists of names of applicants in the Medical Reserve Corps are being sent to this office and are reviewed in connection with the data concerning physicians of the country. So far as the war is concerned, we have on file here at the office the names of the men who have made applications for commissions, with a certain percentage of error due to loss of lists; but we can tell you every one in your state who has made application, who has been commissioned and who is under orders in a large percentage of the cases, and we can tell something about certain individuals as to personal character and professional reputation. That is a point, however, on which we need your help and the help of the county societies. We have a list of the men under orders in each of the several states. We have given to you also a preliminary table of all men in the United States. There are errors due to the fact that we report the men at their permanent addresses, but you will be able to determine how certain groups of doctors have responded to the call and where further enlistment may be obtained after we have available this honor roll. We wish also to hear from each state secretary how he deems this draft can best be conducted in his state. I would suggest that we resolve ourselves into a committee of the whole for the purpose of deciding how we can best put these things over.

The chairman introduced Dr. A. R. Mitchell of Nebraska, member of the war committee of the Board of Trustees, who said: The statements made by Dr. Harris cover everything that I might say. The idea is to get concentrated work and get it quickly. I would call for a committee to draft resolutions.

MOTION TO APPOINT COMMITTEE ON RESOLUTIONS

Dr. E. J. Goodwin of Missouri said: I believe, in view of the fact that we are pretty well informed of the object of this meeting, that it would be well to appoint a committee on resolutions first, and then discuss the topics that the committee suggests. I, therefore, move that the Chair be authorized to appoint a committee of three which shall hand in such resolutions which shall seem to cover the purposes of the meeting for consideration at the afternoon session.

The motion was seconded by Dr. E. G. Balsam of Montana.

Dr. Crum Epler of Colorado asked whether, if the talks were made now, the ground would be gone over again in the afternoon when the resolutions were presented.

Dr. Goodwin said that the object of his motion was to have the committee appointed first so that it could listen to the discussion and then bring in concrete suggestions for action during the afternoon.

The motion of Dr. Goodwin was carried, and the Chair appointed the following committee on resolutions: Dr. E. J. Goodwin, Missouri; Dr. F. C. Warnshuis, Michigan, and Dr. D. E. Sullivan, New Hampshire.

ALABAMA

Dr. H. G. Perry, Alabama, said: One of the troubles under which we have been laboring is a multiplicity of organizations, all trying to do the same work. I am here today as the secretary of the state organization of Alabama, but am also secretary of the state committee of National Defense, Medical Section, and member of various organizations and activities. We organized in Alabama early in 1916 with the retiring president of the state association as president of the organization. That was before the State Committee on National Defense was formed. When the governor was called on to appoint this Committee on National Defense, he took the organization we already had and made his committee identical with the committee already raised. In Alabama we have an organization of medical men in every county in the state who are charged with the execution of the medical laws of the state in their respective counties, and have also jurisdiction such as medical societies have over the professional side of medicine. In each society there are five men who constitute a board of censors. Our central committee organized for the purpose of increasing the membership of the Medical Reserve Corps in the Army. They did not have to go very far in order to get a working committee in every county, and these committees in each county got very busy. A little later we found that with sixty-seven committees and sixty-seven counties, it was hard to get frequent reports and sometimes hard to get cooperation, so a good deal of the work was done by the central committee, the president of the committee and the secretary. Up to April 1, according to the Surgeon-General's Office, we had 333 men to whom commissions had been offered. We have endeavored time and again to get the number of those in actual service, but up to this time have failed to get this list or a list of those who had accepted their commissions. We know of a good many who have been discharged. Out of 333 that we know have been tendered commissions, 134 were in actual service outside of the largest county, which adds another hundred, making 234, leaving ninety-nine still unaccounted for. They will constitute a large problem when we start into this new draft. The thing we have to work out is some plan by which we can judge the local conditions in such a way that we can go to a certain county and put our hands on a certain number of men without reducing the necessities or without jeopardizing the welfare of the civil population.

ARKANSAS

Dr. C. P. Meriwether, Arkansas, said: The Arkansas Medical Society made a complete survey of our state last October through our councilors. The State Committee of the

Council of Defense was inactive. Our report was made to the National Council of Defense, but we got little encouragement; until the last three or four weeks, the Council of Defense in our state had done practically nothing. About three weeks ago, I was made secretary of the state committee by appointment from Washington. The status of affairs in our state is possibly a little different from that of most of the states. We have about 2,680 doctors in our state according to the directory. As we all know, up until 1909 the laws of Arkansas controlling the practice of medicine allowed almost anybody to get a license. As a result we have thirty-seven or thirty-eight undergraduates licensed and carried in the directory. We have from 225 to 250 undergraduate doctors, two commissioned in the Medical Reserve Corps. At the request of Dr. Craig, secretary of the Association, we called a meeting of the officers of the state medical society and have sent a letter making a special appeal to each member of the state society. We have notified the state eclectic society and the homeopathic society to meet with us in Jonesboro, May 7 and 8, at which time the Council of National Defense will send to our meeting Major John T. McLean of the Medical Reserve Corps who will be in a position to enroll all of the men and examine them at that meeting, so that we will get them while they are warm and in the notion. In Newton County they have ten doctors, and not a single one is a graduate. Yell County has forty-five doctors; eighteen are under 45 and only seven are graduates. That is a situation that does not confront many other states. But as Arkansas came over in her Liberty Loan allotment, the first on top, we are coming over with our men, too.

ARIZONA

Dr. E. F. Hardrige, Arizona, said: Arizona is a community of magnificent distances. Physicians frequently travel 50 or 60 miles to see patients. Last week we held a state meeting and certain efforts at drafting a resolution as to what we are willing to follow, were made. We have peculiar conditions on account of the great distances. In Graham County there are over 6,000 square miles with only three physicians. In Arizona, we have large copper industries that must be kept going. In all these institutions, the medical staffs have been greatly depleted. In one company of twenty-one men, five have responded and are already in the Army. In another county, out of seventeen men there are five who have gone. That is a proportion of 25 or 30 per cent. On receiving the call for this meeting, I immediately telegraphed to each county secretary to give me the name, age and number of every physician that had accepted the call or was under orders. I received a list of 217, of whom forty-two have responded. The point I wish to raise is that we are willing to do everything that is possible, but we have an industrial situation that must be taken care of.

COLORADO

Dr. Crum Epler, Colorado, said: I will confine my remarks to the position taken by the physician who does not go. It is not a matter of a lack of patriotism. In my own state we have had forty-four apply according to the quota given us through the medical section of the Council of National Defense. Now why is this? The first proposition is that Colorado has been properly designated as a finishing place for "lungers," and we have in the state a considerable number who did not get finished entirely but who are in good physical condition, healed lungers, doing good business, and yet under the present rules they are not eligible for the reserve corps on account of their histories. It would appear to me after visiting a number of the cantonment camps and seeing some of the healthy, robust, red-cheeked young men there in the division hospitals, that they could be put on more active duty, and a limited service might be provided for the healed lungers in these base hospitals. With the large number in the service and the other large number who have accepted the commissions but have not been called, men ask, What is the use of breaking up a business that has taken years to build up when not all the commissioned men have been called? I know fifty men, some of them as good men as have been commissioned, two of them in one town, who have not been called into active service. Another condition is that men are holding commissions too low for them. Physicians are asked to accept commissions lower in rank than are given to their assistants. That is a condition that exists in Colorado and other states in which I have talked. Another condition is that the deadwood about the cantonments needs to be removed. When the Surgeon-General says "We are now asking you to join the cause; we need you," physicians will go—every one of them.

CONNECTICUT

Dr. John E. Lane, Connecticut, said: Connecticut is pretty well ready on the medical side. From the first of last October the medical society has worked with the Council of Defense—the men on the medical section—and the secretary's office of the state society has sent out circulars. There is perfect harmony, and if this scheme goes through we can make a war committee in a week in our state. Connecticut is prepared to furnish her quota and more. In Connecticut it would be useless to have county committees; the state is small and the state society can handle it all. By that plan the personal equation of a committee working in a local community is eliminated. Some counties have only seventeen physicians. The state society can do this work without arousing personal antagonisms. The chairman of the State Council of Defense, Dr. Brown, has done magnificent work. The physicians have been classified into those who should go and those who should stay at home, and Dr. Brown has personally gone through the state asking physicians to appear before them, and he knows the conditions with reference to every physician. One thing we need is direct cooperation so that the work we have done will not be undone. Some months ago the National Council of Defense sent out a questionnaire that we were to classify these physicians and should not injure any communities. These answers were included in the Surgeon-General's letter two weeks ago. Within three days' time the State Council of Defense in our state without getting information from the local council sent out two letters urging men to join the Medical Reserve Corps of the Army and Navy. The State Council would have taken the very men who should have been left—the teachers in the medical schools and the like—thus spoiling the work we had done.

DISTRICT OF COLUMBIA

Dr. H. C. Macatee, District of Columbia, said: The medical society of the District of Columbia occupies a position equivalent to the county society in the states. The data published in the list of the American Medical Association give the district 1,514 physicians. One of our great difficulties has been this exaggerated estimate for the District of Columbia. The telephone directory which covers the whole district gives only 759 names. That would cover all the men who are active practitioners of medicine, and therefore covers all the men available from that jurisdiction. On that basis instead of having a percentage representation of 12.8 in active service, we have a percentage representation of 27.6. The medical society of the District has a membership of 560 and a male membership of 530. It has 133 in the various public services, making a percentage of 25. In looking over the lists, making a rough estimate of the availables, I find 189 men still to be approached in this matter. Out of these, many are members of the medical society; many of them will be found unavailable by reason of civil needs, physical disqualification, etc.; so that for the District we cannot approach the matter from the basis of a quota. I shall recommend to our society that we simply cull over all the men possible, keeping in view the needs of the community, and put all those men to be commissioned and leave the public services as these need. I feel that I must also endorse the remarks of the secretary for Connecticut that there is a great deal of feeling in Washington on account of the disparity on account of commissions granted. These commissions are granted on some basis that we are unable to fathom, because the relative standing of the men in the communities is not taken into consideration. We are strongly of the opinion that commissions should be made of the lowest grade and that promotions should go according to merit. I am also secretary of the state committee of the Council of National Defense, and we have been unable to do any effective work because we have been ignored, superseded or overridden by central authority.

ILLINOIS

Dr. W. H. Gilmore, Illinois, said: I understand that the idea of the meeting is to get the 5,000 physicians as quickly as possible. The discussion has been too general. We should come down to the point of how to go about it to get these men. As secretary of the State Council of Defense, and chairman of the state licensing board, particularly of the latter board, I have been in personal contact with men all over the state. I have made two trips over the state recruiting for the Medical Reserve Corps. From Springfield south I have found that 45 per cent. have accepted commissions, and from Springfield to Cook County, 18 per cent.

I have no confidence in anything being done locally. If it comes direct from the American Medical Association to these men we will get results. How are you going to do it? How can you do it? We have a list of the men under 45. We have the number in the reserve corps. Let the letter from the President and Secretary of the American Medical Association say to John Jones, "You are of the proper age and qualifications. Your county is short so many men. Get together with the men who have not enlisted in the Reserve Corps and decide who is to go, because some of you have to." They will go then. When I came back from my trip I was cocked and primed to recommend the draft for physicians. We had the day set to discuss the draft for physicians. An editorial in The Journal knocked it into a cocked hat, and I have never ceased to believe that editorial was inspired.

INDIANA

Dr. Charles N. Combs, Indiana, said: Dr. Gilmore's pertinent remarks offer a definite field for some work. Some criticisms will have to be cleared away before the men will take seriously this letter even from the American Medical Association. There has been a difficulty encountered because of lack of statements from the Surgeon-General's Office. The statements issued from various sources leave the mind in confusion. There is difficulty on account of statements regarding the mortality rate of physicians in the service; on account of resignations and discharges, which of course men staying out of the service read with avidity. There is difficulty caused by the long wait for assignments that has been spoken of, and also on account of unfair distribution of favors as to rank by which some men who have not a high standing in the medical profession are given higher rank than others, for some unknown reason. The printing of news, even in the newspapers, regarding the lack of definite need for men is unfortunate; also the uncertainty as to what assignment men are going to get when in the service. The War Department issues but one answer, and that is that you will probably be assigned to the work you are accustomed to doing, but no promises are made. In my own experience it seems to me that the government requires us to go back to the experience of twenty years ago and be general specialists. We are planning to have meetings in every county in the state on Lusitania Day, May 7. We are going to get men in uniform assigned to these meetings so that the men who enlist will have the stronger appeal. Men have been enheartened on account of the survey made by Dr. Squier, for conditions are changing and more attention will be paid to particular qualifications along certain lines.

IOWA

Dr. T. B. Throckmorton, Iowa, said: Conditions that exist in Iowa are no different from those of other states, and I cannot help but feel that some of the difficulties of raising men for the Medical Reserve Corps have come through ignorance. I have learned more regarding the needs of the corps during the last week or ten days than since the declaration of war. We have had no organized effort made in the way of obtaining volunteers save that which came through the Council of National Defense, through the medical section of the State Council of Defense. Nothing succeeds without organization. In the first place, we have had no one competent in Iowa to answer questions asked by applicants concerning admission into the Reserve Corps. Early in the season it was hard to obtain blanks for those who did apply. No one was there to tell the doctors where to go for physical examination, and above all, we had no one there competent to explain to the doctor when he called by phone or in person as to the real necessity of volunteering. I did not know until a few days ago really how many men the War Department wanted from Iowa. I recently got a letter saying that 462 were accepted and commissioned, and that they expected 350 more. That is the first information I had. A man is not going to give up his business unless there is a real necessity, and while I am not here to pick differences with these gentlemen concerning Iowa's apparent lack of patriotism, if it may be so stated—because we have from 12 to 13 per cent. of the profession now in the Reserve Corps—still I think it is a question of ignorance. There is going to be great good from this conference, because we are going to put the facts before physicians and show them there is a necessity of obtaining volunteers in the Medical Reserve Corps. I am here to listen to the dictates of this conference and carry back whatever wishes it has, and so far as I am concerned I am willing to do my bit with all my heart and soul.

KANSAS

Dr. L. F. Barney of Kansas said: I am not prepared to make a report from Kansas. The secretary, Dr. Hassig, left recently for service and I am not in position to state what conditions are. Dr. Throckmorton has perhaps expressed conditions in Kansas very well. There has been no knowledge of conditions and what is needed. It is necessary for some one to make up the minds of a great many physicians. We have got to have something brought to bear on the individual physician who is convinced that his conditions are different from those of some one else. Each one has his own reasons for not going, and under the best plans it has been pretty hard to get away from those individual reasons; but when we have these things pointed out, and when some one in authority goes to them and says, 'This man is more available for service than some one else," I think we shall have a better response.

KENTUCKY

Dr. P. E. Blackerbie, Kentucky: Dr. A. T. McCormack, the secretary, is now in the service. Dr. J. N. McCormack was not able to be here and asked me to represent him. As long as Dr. Arthur McCormack was in Kentucky following up the work of raising the quota, things went along well, and as a climax at the meeting of the State Association forty Kentucky physicians were examined at the meeting, and 70 per cent. of these were commissioned. Kentucky has 540 men commissioned. I do not know how many are actually in the service. Unfortunately, two things militate against our growing: The first one was the unfortunate court-martialing of the retiring state president on charges on every count of which he was vindicated. That had some influence in the state against men offering their services. And then again, as the doctor from Colorado said, a lack of understanding of the men in the service as to the time they would be called for active work had its influence in holding back men. We have just prepared a classification of physicians in Kentucky in which we are trying to determine the number of men available out of the 1,500 physicians not examined, and in this classification we are showing the communities and the required number of physicians, their family relations, whether they have children or not, etc. On this list there are 460 men yet available, and we hope without draft to get at least half of these, which will keep Kentucky in the same position she now has. I am by Dr. McCormack requested to say that if this conference recommends the draft, Kentucky is behind it, or in whatever move is instituted here. Personally, I am very much in favor of the move of the gentleman from Illinois (Dr. Gilmore) to the effect that the American Medical Association make a personal appeal to every available man in each state in the United States to go into the service. I think it ought to be stated in that appeal emphatically that the result of this work of the American Medical Association would forecast either a draft or not a draft.

LOUISIANA

Dr. P. T. Talbot, Louisiana, said: I was recently elected secretary of the state society. In Louisiana conditions are about the same as mentioned by the other secretaries. The state medical society in session last week passed resolutions endorsing the movement of the American Medical Association, and wants to lend its best efforts to do anything the American Medical Association desires. As secretary of the Orleans Parish Society for a number of years, I have been intimately associated with physicians throughout the state. We feel in Louisiana that if we have been negligent in this response, it has been due almost entirely to the fact that the doctors did not realize that they are needed. They did not realize that because the needs have not been expressed through organized medicine. We feel that if this plea comes from the American Medical Association, through its subsidiary societies, there will be excellent results; and the state medical society is anxious for some plan to be suggested by this meeting to enable it to fulfil its purposes to the country. In regard to the solution of this problem, the securing of enlistments through organized medicine, the state medical societies, appears most expedient to me. The Orleans Parish Medical Society, representing the largest medical center in Louisiana, has instructed me to say that it wishes to lend all possible aid in securing the enlistment of physicians. They are ready and anxious to go. They are waiting for a definite call from the American Medical Association to respond, and I am sure when the call is sent out, Louisiana will come forward with all that is needed.

MAINE

Dr. B. L. Bryant, Maine, said: The population in our state is scattered. The great majority of towns contain from one to two physicians, and often they have to cover a great deal of territory. It is going to be quite a problem to get the quota from the state of Maine, but I think it can be done after a careful reorganization. There has been practically nothing done outside of the work of the Council of National Defense. The heads of that council are now in the service, and since they went away several months ago, practically nothing has been done in the organization. I think we have in the service practically 150. The other fifty must come from the populous districts—the cities—to a great extent. Our next state meeting comes June 5. We stand ready to put the plan through. I want to get information of what has been done, which our Council has not been able to get hold of. It is purely a matter of getting a plan and then adopting it in the state. I believe then the state will come up over her quota. The men who have gone have come irregularly. For instance, out of one town with eleven doctors, five have gone. Out of another town with fifty, sixteen; in another with 160, only twenty-four; and another city with twenty-two has sent none. It is simply a question of organization, and then for the organization to get after these men. The best way to do that is what I came to find out.

MICHIGAN

Dr. F. C. Warnshuis, Michigan, said: There has been a multiplicity of effort. Many things we have attempted to do have been undone. Many things we have done have not succeeded. I think we have got to learn as doctors one thing: that we must not ask ourselves what are we going to get out of it, but what are we going to put into it; not what our rank is, but what is our individual part to do to lick these contemptible curs, the Huns. I myself cannot be a lieutenant. I have resigned three times and made application, and they have said, "You stay at home. You are of more value there." So far as I am concerned, until it is over I shall remain a high private in the rear rank, but I will do what I can. It is a question we must carry home: not What are you going to get out of it? but What are you going to put into it? We are going to bear the test, and the sooner we realize it the sooner we are going to come across. I know we shall go home and send to General Gorgas a message not to worry for one minute; that he is going to have sufficient doctors to take care of the work in this war. The great problems are what we are going to do to supply the men for the Army and what we are going to do to protect the communities at home. We cannot take away all the men from the rural districts. We have already found conditions whereby communities are totally bereft of medical attendants. During the winter months I traveled miles and miles to visit the only physician in a county, who himself was ill with pneumonia. We must take the doctors from the larger cities, and we need no further organization. We have the organization. I do not believe we have need for further state committees and county committees if we have good secretaries. The secretary will respond all that is necessary to you as state secretary if you approach him in the right manner. I think our conference should resolve itself into a committee to determine how we are going to get these men. I myself am inclined to have a draft made of every doctor, if necessary. Put every man in the Medical Reserve Corps and then perfect our organization so that when the Surgeon-General needs doctors he can say, "We want fifteen, or fifty, men from your state." And when that man gets your order he is going and there will be no dearth of doctors.

MISSISSIPPI

Dr. T. M. Dye, Mississippi, said: I am acting secretary; our secretary is in camp. I am here to learn what we can do in Mississippi. All the work done in Mississippi has been done through the Council of National Defense. The state association meets two weeks from today, and we are prepared to do anything you tell us to do. We have no advice to give.

MINNESOTA

Dr. Thomas McDavitt, Minnesota: We are up to the quota as far as the doctors are concerned, and we are going to get a lot more. The principal trouble we are having is a dearth of doctors in the rural communities. We have a great sufficiency of doctors in the cities. They should be transferred. I believe Uncle Sam is going to make a draft of some kind and transfer men from the cities to the country where they are needed, and that will be the solution of this whole question.

The reports of the remaining state secretaries will appear next week.

AFTERNOON SESSION

The conference reconvened at 2 p. m. and was called to order by the Chairman, Dr. Thomas McDavitt.

The following is an abstract of the proceedings of the afternoon session. A complete report will appear next week.

The following state medical associations were called on for reports, and each state secretary or his representative gave an epitome of the work that had been done and is now being done in the state: Missouri, Dr. E. J. Goodwin; Montana, Dr. E. G. Balsam; Nebraska, Dr. Joseph M. Aiken; Nevada, Dr. M. A. Robinson; New Hampshire, Dr. D. E. Sullivan; New Jersey, Dr. Thomas M. Gray; New Mexico, Dr. R. E. McBride; New York, Dr. Floyd M. Crandall; North Dakota, Dr. H. J. Rowe; Ohio, Dr. E. O. Smith and Dr. B. R. McClellen; Oklahoma, Dr. Horace Reed; Oregon, Dr. Clarence P. McCusker; Pennsylvania, Dr. Cyrus Lee Stevens, Rhode Island; Dr. J. W. Leech; South Carolina, Dr. Edward A. Hines; Texas, Dr. T. C. Chase; Utah, Dr. W. Brown Ewing; Vermont, Dr. W. G. Ricker; Virginia, Dr. Paulus A. Irving; West Virginia, Dr. J. Howard Anderson; Wisconsin, Dr. Rock Sleyster.

Dr. Arthur Dean Bevan, President-Elect of the American Medical Association, spoke of the importance of a survey of every state with a view of recording exactly how many medical men there are in each state, and how many have applied for commissions in the Medical Reserve Corps. This work, he said, can be perfected, as is contemplated and as requested by the Surgeon-General of the Army, by the American Medical Association through its county and state societies.

The Committee on Resolutions, consisting of Drs. E. J. Goodwin, Missouri, chairman; F. C. Warnshuis, Michigan, and D. E. Sullivan, New Hampshire, reported through its chairman, Dr. Goodwin.

The report was freely discussed by Drs. G. H. Perry, Alabama; C. L. Stevens, Pennsylvania; Crum Epler, Colorado; R. E. McBride, New Mexico; Thomas N. Gray, New Jersey; T. B. Throckmorton, Iowa; J. E. Lane, Connecticut; W. Brown Ewing, Utah; F. C. Warnshuis, Michigan; I. C. Chase, Texas, and others. The report was finally modified by substituting the following:

Moved that the secretaries of state medical associations request the presidents of their respective state associations to appoint a war committee of three immediately, one of whom may be the secretary of the state association, for the purpose of coordinating the profession of each state for war work.

Motion seconded and carried.

Dr. W. Brown Ewing, Utah, moved that it be the sense of the conference that each secretary immediately on arriving home shall elicit the support of every county society in the state association, in order that this important matter may be brought to the attention of physicians as soon as possible.

Dr. F. C. Warnshuis, Michigan, moved that the chairman of the conference (Dr. Thomas McDavitt) be delegated to represent the state secretaries at the conference to be held at Washington, Saturday, May 4.

Seconded and carried.

Dr. I. C. Chase, Texas, moved that the conference request the War Board, after conference with the Surgeon-General, to draw up a form of questionnaire as a guide for the collection of the data regarding individual doctors throughout the United States.

Seconded by Dr. Rock Sleyster and carried.

On motion, which was duly seconded and carried, the conference then adjourned.

Medical Mobilization and the War

Body of Colonel Reno Recovered

The body of Lieut.-Col. W. W. Reno, mysteriously lost at sea while he was returning from France, has been recovered off the coast of Nova Scotia, and has been sent to Cleveland for burial.

Wounded in Action

Capt. Hyman Green, M. R. C., attached to the Royal West Kent Regiment of the British army, was wounded in the recent fighting in Flanders and northern France.

American Medical Officer Awarded French War Cross

Lieut. George Patton, M. C., of New York City, has been awarded the French War Cross for courage shown in caring for wounded men during a heavy bombardment of gas shells. Lieutenant Patton remained at his task without the protection of a gas mask.

Cuba to Send Medical Unit

Voting under suspension of the rules, April 10, the senate of Cuba adopted a resolution to send to France a medical unit consisting of 100 physicians and an equal number of nurses, to represent the Cuban Red Cross.

American Medical Officer Missing

Lieut. John S. Abbott, M. C., of Minneapolis, was reported missing on April 15. Lieutenant Abbott, who had answered the appeal for aid made by the British Medical Service, was attached to the Eighteenth Field Artillery of the British army, which has been engaged in the present great drive in Flanders.

Personnel of the Medical Department

For the week ending April 26, 1918, the personnel of the Medical Department of the Army included:

MEDICAL CORPS: 843, including 1 major-general, 65 colonels, 110 lieutenant-colonels, 239 majors, 1 captain and 427 lieutenants.

MEDICAL RESERVE CORPS: 18,693, including 1,221 majors, 4,487 captains and 12,985 lieutenants. On active duty: 16,359, including 1,105 majors, 4,029 captains and 11,225 lieutenants.

MEDICAL CORPS, NATIONAL GUARD: 1,204, including 16 lieutenant-colonels, 253 majors, 146 captains and 789 lieutenants.

MEDICAL CORPS, NATIONAL ARMY: 111, including 3 brigadier-generals, 11 colonels, 88 lieutenant-colonels and 8 majors.

DENTAL CORPS, 209; DENTAL RESERVE CORPS, 5,220, of whom 1,369 are on active duty; DENTAL CORPS, N. G., 258; VETERINARY CORPS, 17; VETERINARY RESERVE CORPS, 1,434, of whom 786 are on active duty; VETERINARY CORPS, N. G., 50; VETERINARY CORPS, N. A., 412; SANITARY CORPS, 1,030, and AMBULANCE SERVICE, 157, constitute the remainder of the commissioned personnel.

The DISCHARGES in all branches of the service to date are:

Causes	Number M.R.C.	M.C.N.G.	D.C.N.G.	San.C.

DISEASE CONDITIONS AMONG TROOPS IN THE UNITED STATES

From Telegraphic Reports Received in the Office of the Surgeon-General for the Week Ending April 19, 1918

1. ANNUAL ADMISSION RATE PER 1,000 (DISEASE ONLY):
All Troops
National Guard Camps 1,745.5
National Army Camps 2,033.0
Regular Army 1,742.0
1,515.8

2. NONEFFECTIVE RATE PER 1,000 ON DAY OF REPORT:
All Troops
National Guard Camps 40.1
45.3
National Army Camps 54.2
Regular Army 43.6

3. ANNUAL DEATH RATE PER 1,000 (DISEASE ONLY):
12.9
All Troops 6.5
National Guard Camps 17.3
National Army Camps 12.4
Regular Army

EXPERIENCES OF A MEDICAL OFFICER WITH THE BRITISH ARMY DURING THE RECENT ACTIVITIES IN FLANDERS

A most interesting letter has been received by Dr. J. W. Pettit of Ottawa, Ill., from his son, Lieut. Roswell T. Pettit, M. R. C., U. S. Army, attached to the British Army during its withdrawal from San Quentin. Lieutenant Pettit describes his experiences during this movement from the time of its commencement until he was relieved from duty, a period of nine days. His narrative is most interesting because he speaks of happenings which had only just occurred and which are not apt to be included in any official reports. It is a narrative of personal experiences. He speaks only of what he saw and did, not of what he heard. He had not seen a newspaper for eight days, nor had he received any mail, therefore his knowledge of what was going on elsewhere came to him in the nature of rumors. For instance, he says:

> All I know is that on this part of the front the Germans attacked us in overwhelming numbers, in places ten divisions to our one; that they suffered terrible losses, but finally broke through our lines of defense, one after another, and fighting for the most part, a rear guard action, we have retired about fifteen miles in a straight line.

The battle was expected for a week; everybody was ready to move on thirty minutes' notice. Medical officers had made tours of reconnaisance, and definite methods of evacuation of the wounded had been worked out. Finally the storm broke, and Dr. Pettit describes the commencement of activities as follows:

> The boche opened up on us at 5 a. m., March 21, with the heaviest barrage I have ever heard. "Stand to," was sounded, we turned out, dressed, and had all our equipment packed in thirty minutes. Then we sat down and waited for orders to move. The barrage kept up continuously, sometimes heavier and then of less intensity, sometimes it seemed to be the north of us and then suddenly it switched to the south.
>
> Our balloons were up as soon as it was light and the aeroplanes were buzzing over our heads. The ground mist gradually cleared and the Germans put a hail of shrapnel on our camp and we all took cover, but three men were hit.

The British troops then retired, amid the most terrific shell fire. Tanks went into action. The troops were still about a mile from the front line. At this point Dr. Pettit opened up an aid post under the crest of the hill to take care of what wounded came in while the troops were getting into position. He says:

> Shrapnel was bursting in the air, shells were whizzing overhead, and our guns behind me were belching forth the fire. The noise was deafening.

That the doctor is possessed of a sense of humor as well as keen powers of observation is shown by the following extract from his letter:

> A railroad ran through the valley and an engine pulling a couple of flat cars was going by. A couple of soldiers were sitting on the rear truck swinging their feet. A shell burst on the track and only missed the last car about fifteen yards. Neither man was hit and the train went blithely on.
>
> By this time it was getting along toward evening, the sun was sinking in the west, and finally went down a great ball of fire. At the time, I remember, I noticed its color. It was blood red and had a sinister look. Was it my imagination, or might it have been a premonition? At any rate, I shall never forget the color of the sun as it set that night at the end of the first day of probably one of the greatest battles in history. It certainly didn't look good to me.

Some of the hardships which the army surgeon is compelled to undergo are well outlined by Dr. Pettit:

> I opened an aid post in an old dugout and settled down to sleep until morning. You may think it funny that one could sleep under such conditions, but I had been up since 5:30, had tramped about six or seven miles, had had a rather trying day and was dog tired.
>
> So I settled down on the rough plank floor and was soon asleep. I must have been asleep a couple of hours when a runner came from headquarters and told us we were to move off immediately. I looked at my watch and it was 1:30 a. m. on the second day.

And then there came some more marching, with orders to establish an aid post near battalion headquarters. It was at this time that Dr. Pettit walked in the wrong direction, toward and not away from the enemy. Being set right by the company commander, he about faced and went in the other direction. Then it came to pass that the doctor ran into a piece of good luck:

> On the way back I found a gallon can full of water, got into a corrugated iron shelter and had a wash and a shave. It certainly felt good. I do not believe I had washed for thirty-six hours.

Then things began to liven up:

> Headquarters had been established in a sunken road with banks about 15 feet high on either side (later this cut was half filled with dead). My aid post was in a dugout nearby and gradually things got hotter and hotter.
>
> Our men had dug themselves in and were popping away with their rifles. The field batteries behind us were putting up a barrage, aeroplanes were circling overhead, both ours and the Germans'. The Germans put up a counter barrage; the machine guns were going like mad. I was standing with the colonel on a little rise of ground above the sunken road when the Germans broke through about a mile to the north of us. They could be plainly seen pouring over the ridge in close formation.

TANKS GET INTO ACTION

> Then the tank came up, and you should have seen them run! Just like rabbits! The tanks retired; the boches reformed and came at it again. They tell me that at certain places our men withstood fifteen successive attacks and that the Germans went down in thousands. One Welshman told me that his gun accounted for seventy-five in three minutes during one wave.
>
> Machine gun bullets were nipping around me, the shell fire was getting hotter, and even though it was a wonderful sight to watch I decided "discretion was the better part of valor," or something like that and got down in my dugout.
>
> I was sitting there smoking a cigaret when my orderly came down and said I was being relieved and was to go back and work with the ambulance. Fifteen hours later the man that relieved me was captured.

From this point on, Dr. Pettit's description is so intensely interesting that nothing short of reading every word can convey an adequate picture of what his experiences were at this time:

> I went back to the advanced dressing station through the hottest shell fire I ever experienced. More than once I went down on my face when a shell burst and the pieces went whizzing over my head. I spent the night in a mined village where the advanced dressing station was located, and all night they shelled it to blazes. It was remarkable how few casualties we had.
>
> About 11 o'clock the morning of the third day a shell blew in the side of our post, but luckily no one was hurt. We stuck to it until about 4 in the afternoon, when we saw our men retiring over a ridge in front of us, keeping up a continuous machine gun and rifle fire, and we beat it back to another village and opened another post.
>
> About 10 o'clock on the morning of the fourth day Lord Thyme, my colonel when I was with the battalion, stumbled into the shack where I was sitting. He looked like a ghost. He had lost his hat, his face was covered with a four days' beard, the sweat had traced tracks in the dust from his forehead to his chin. His sleeve was torn and bloody and he had a gash in his arm where he had been struck by a piece of flying shell case.
>
> "My God, doc, are you here?" he said. "You got out just in time. The battalion is all gone. The sunken road is filled with dead—mostly Huns, damn 'em. The line broke on the right; we were surrounded, and at the last we were fighting back and back. Only thirty of us got away."
>
> So we knew the boche had broken through to our right and our left, and it was a question of how long it would be before we, too, were surrounded, but we wanted to stick it out as long as we could.

TOLD TO RETIRE

> But not more than an hour later a medical officer rushed in from one of the battalions and between gasps for breath told us the Germans were on the edge of the village, had shot him through the sleeve with a machine gun bullet (luckily that was all), and for us to beat it.

Let me tell you we did. I threw my knapsack and made the first hundred-yards in nothing flat and then settled down to a walk because I was so out of breath I couldn't run any more.

The incessant scream and crash and bang of the shells kept up and the rat-tat-tat of the machine guns never ceased. The village immediately behind us was a seething mass of brick dust, smoke, flame, and bursting shells. We were told on our way back that a stand was to be made behind this village, so we circled around it and took up a position about a half mile behind it at a crossroads.

Unfortunately for us, a six inch battery came into action about fifty yards from us and, aside from the harassing effect of the terrific noise, batteries are always unpleasant neighbors, as they invite shell fire. We stopped here until 10 o'clock at night, when we were ordered to retire.

There was no way of getting out the wounded that we had collected, so the stretcher bearers carried them on their stretchers for six or seven miles. In fact, we all helped, and when we arrived at our destination at 4 o'clock in the morning of the fifth day we were all in.

I could hardly move, but after two big bowls of hot tea and some hard tack I turned in on the floor and slept like a log for four hours, when we moved to another place and opened a dressing station.

And so it went for three days more, open a dressing station, retire (sometimes on the run), long marches, very little to eat except what we foraged from abandoned camps and dumps, dog tired, sleeping when and where we could, and finally the division was relieved. We now saw our first civilians, and last night I slept in a bed. It wasn't much of a bed, and the mattress was full of humps, but to get my boots off my sore and aching feet, to stretch out, and know I wouldn't be routed out in fifteen minutes—well, you couldn't have bought that bed from me for $100.

Then the good doctor is reminded of Robert W. Service's description of the retreat from Mons:

Tramp, tramp, the grim road, the road from Mons to Wipers;
 I've 'ammered out this ditty with me bruised and bleeding feet;
Tramp, tramp, the dim road—
We didn't 'ave no pipers—
 All bellies that were 'oller was the drums we 'ad to beat.

On the ninth day Dr. Pettit was relieved from duty with the British army and assigned to the American Expeditionary Force. All of his kit had to be burned to prevent it from falling into the hands of the enemy. While the doctor was "kitless" he certainly cannot be accused of being "witless."

ORDERS TO OFFICERS OF THE MEDICAL CORPS AND OF THE MEDICAL CORPS OF THE NATIONAL ARMY

To Camp Crane, Allentown, Pa., base hospital, from Fort Oglethorpe, Major WILLIAM H. ALLEN.

To Camp Dix, Wrightstown, N. J., and *Camp Upton,* Long Island, N. Y., for duty, and on [illegible] Meade, Lieut.-Col. PHIL[illegible] *er station,* from Camp

To Camp Dodge, Des [illegible] Rockford, Ill., *Camp Custer,* Battle Creek, Mich., *Camp Sherman,* Chillicothe, Ohio, and *Cleveland, Ohio,* for duty, and on completion *to his proper station,* Lieut.-Col. WINFORD N. SMITH.

To Camp Lee, Petersburg, Va., for temporary duty, and on completion *to his proper station,* Col. WILLIAM H. MONCRIEF. For temporary duty, from Camp Wheeler, Lieut.-Col. CONDON C. McCORNACK.

To Camp Lewis, American Lake, Wash., for duty, from Seattle, Lieut. CARLTON L. VANDERBOGET.

To Camp Perry, Ohio, for duty, from New Haven, Major ARDEN FREER.

To Camp Pike, Little Rock, Ark., for duty, from Camp MacArthur, Lieut. HALL G. VAN VLACK.

To Camp Zachary Taylor, Louisville, Ky., and *Camp Sherman,* Chillicothe, Ohio, for duty, and on completion *to his proper station,* from Camp Shelby, Lieut.-Col. ROBERT M. BLANCHARD.

To Cleveland, Ohio, for duty, and on completion *to his proper station,* Lieut.-Col. WINFORD N. SMITH.

To Fort Riley for inspection, and on completion *to their proper stations,* Major-General WILLIAM C. GORGAS, Col. EDWARD L. MUNSON.

To Muncie, Ind., Cincinnati, Ohio, and *Indianapolis, Ind.,* for inspection, and on completion *to his proper station,* from Louisville, Major JOHN P. FLETCHER.

To Newport News, Va., for duty, and on completion *to his proper station,* Lieut.-Col. EDGAR KING. For duty, from San Francisco, Major ERNEST C. McCULLOCH. *To Newport News, Va., Locust Point, Md.,* and *New York City,* for inspection, and on completion *to his proper station,* from Washington, D. C., Major FRANCIS N. STRONG.

To New York City for duty, and on completion *to his proper station,* from Camp Crane, Col. ELBERT E. PERSONS. Neurological Institute, for instruction, and on completion *to Hoboken, N. J.,* base hospital, from Fort Des Moines, Major ARTHUR C. STOKES.

Clarence Cutter of Boston, and are free to the medical profession and the press.

MINNESOTA

Major Jump to Recruit Physicians.—Major H. D. Jump, M. R. C., U. S. Army, will address the physicians of Minnesota, their wives, families and friends, in the Radisson Hotel, Minneapolis, May 18. Major Jump will speak on the needs of the government for 5,000 additional men for the Medical Reserve Corps of the Army, and for 2,000 for the Medical Department of the Navy. It is the earnest request of the Surgeon-General that all physicians under 55 years of age register themselves as ready for service. There will be a commissioned officer from the government present at this meeting in Minneapolis to examine all applicants for commissions. It is hoped that as many of the physicians of the state as possible will attend this meeting. It will be a patriotic meeting with prominent speakers present.

Minneapolis Clinic Week.—The clinic held in the twin cities, April 8 to 12, as already announced, was organized by the clinical section of the Hennepin County Medical Society. Various committees were appointed to carry on the work. In preparation for the session, the entire northwest states of Minnesota, North and South Dakota, Montana and the western section of Wisconsin were thoroughly circularized. During the session week, a daily bulletin was issued giving full advices as to all clinics. Nearly 300 physicians outside the twin cities registered. There were 158 clinicians and the clinics were held at fourteen different hospitals.

Special clinics in all the departments of internal medicine were given and clinics were held by the various specialists. In the afternoon there was a general session at the Radisson Hotel, where moving picture films were shown, and demonstrations were given, especially lantern slide demonstrations and such other material as could be presented without a didactic lecture.

MISSISSIPPI

Health Officer Discharged.—It is reported that the executive committee of the state board of health, April 6, summarily discharged Dr. Rockwell E. Smith, health officer of Smith County, recently charged by the military authorities as having accepted money to grant exemption certificates to selective service registrants.

Sanatorium Committee.—The following is the sanatorium committee of the state board of health: chairman ex-officio, Dr. C. D. Mitchell, president of the board, Jackson; secretary ex-officio, Dr. Waller Leathers, Jackson; Drs. Thomas H. Seay, Laurel; Harvey F. Garrison, Seminary; J. Harvey McNeill, Olive Branch, and Willie H. Watson, Brandon.

MISSOURI

Physician Wins Suit.—In the suit for $16,500 damages brought by Miss Juliette Wurst against Dr. Remy J. Stoffel, wherein it was charged that the defendant had torn off the hat of the plaintiff, jerked her to her feet, and pulled her hair when she failed to stand during the playings of the "Star-Spangled Banner," April 4, the jury, after a short deliberation, rendered a verdict in favor of the physician.

Personal.—Dr. George P. Pipkin, formerly superintendent of the Kansas City General Hospital and health commissioner of the city, who was obliged to go to New Mexico a year ago on account of a physical breakdown, has returned recovered.——Dr. Max C. Starkloff, health commissioner of St. Louis, has been seriously ill with influenza.——Dr. Thomas T. Sawyer has succeeded Dr. Joseph B. Cowherd, who resigned as physician-in-charge of the eye, ear, nose and throat work of the school hygiene staff of Kansas City.

MONTANA

New Hospital.—Ground was broken for the new Deaconess Hospital at Billings, March 15.

Override Antivaccination Protests.—At a meeting of the state board of health in Helena, April 6, it was decided, despite protests from Butte, to adhere to the board's policy of compulsory vaccination. Laurel was added to the list of towns that have been ordered to vaccinate all their school-children at once.

Antituberculosis Work.—The field secretary of the state society for the study of prevention of tuberculosis has organized a public health society for Cascade County, and is organizing a similar society in Lewis and Clark County. The purpose of these organizations is to promote the study and prevention of tuberculosis, the establishment of tuberculosis sanatoriums and the opening of free tuberculosis clinics.

NEBRASKA

Dinner for Base Hospital Staff.—Dr. and Mrs. August F. Jonas, Omaha, gave a dinner, March 20, to members of the committee of physicians who organized the University of Nebraska Base Hospital Unit No. 49, which has been ordered to mobilize. The guests of honor were Major Arthur C. Stokes, director, and Major Charles A. Hull, chief of the surgical service of the unit.

Hospital Contract Awarded.—The contract for the erection of a new hospital building at the state industrial school for boys, Kearney, has been awarded to Ernest Rokahr, Lincoln, for $22,465 The building will be paid for out of the cash fund of the institution, which has been accumulated by the sale of products raised by the inmates on the farm connected with the institution.

NEW JERSEY

Medical Group Elects New Officers.—The medical group of the Trenton Chamber of Commerce met, April 1, and elected Dr. Ira C. Leedom, chairman, and Drs. Walter T. Madden, and E. Ginnelley, vice chairmen.

Personal.—Dr. C. Hewson Canning, Atlantic City, fell three stories through an elevator shaft, March 23, fracturing his skull and sustaining other serious injuries.——Dr. H. L. Goddard, Vineland, has been appointed head of the bureau of juvenile research under the Ohio State Board of Administration, with headquarters in Columbus.

NEW MEXICO

Ban on Legalized Vice.—At a conference held at Santa Fe, March 29, by Dr. James A. Massie, president of the state board of health, Assistant Attorney-General Hatch, and Lieut. Paul Papenoe, representing the Surgeon-General of the United States Army, stringent measures were adopted to prevent the spread of venereal disease. It was decided that licensed houses of ill fame be abolished after April 15, and the reporting of venereal disease was made compulsory. The governor has agreed to provide $3,500 to put these regulations into effect until the legislature convenes.

NEW YORK

State Closes Brooklyn Hospital.—At a special meeting of the state board of charities, held April 25, orders were issued closing the old Williamsburg Hospital, at Bedford Avenue and Third Street, in the Williamsburg section of Brooklyn. This order was prompted by the dangerous and unsanitary condition of the antiquated building. The institution was recently merged with the Eastern District Hospital to which institution many of the patients, following the order to close the Williamsburg Hospital, were removed.

Extension of Tuberculosis Work.—The details of a movement to aid local health authorities in dealing with tuberculosis growing out of the war conditions have been announced by the tuberculosis committee of the New York State Charities Aid Association. Two physicians, Dr. Elliott Washburn, former superintendent of the state tuberculosis sanitarium at Rutland, Mass., and Dr. Charles S. Prest of the New York State Department of Health, have been placed at the disposal of authorities throughout the state to aid in establishing dispensaries and providing medical oversight and supervision for tuberculous patients. It is estimated that the draft has revealed 22,000 cases of tuberculosis, in the great majority of which the patients must remain at home and be cared for. These cases serve to emphasize the need for a vigorous renewal of antituberculosis work.

New York City

City Hospitals Taken for Army.—After a conference between Mayor Hylan and representatives of the federal government, announcement is made that the government will take over the Sea View Hospital, on Staten Island, and the Otisville Sanitorium, at Otisville, N. Y. These institutions will be operated jointly by the federal government and the city officials. The government is planning to expend about $450,000 in additional wards and beds.

Government Designates Hotels for Nurses.—Ten New York hotels owned and managed by the Knott Brothers have been designated by the government for the care of Red Cross nurses during their stay in New York when they have been assembled for transportation. These hotels have been selected because of their convenience to steamship piers and because some of them have been designated for use as base hospitals and replacement stations.

Annex for Flower Hospital.—Flower Hospital celebrated April 21 as Loyalty Day. At the exercises on this occasion, Dr. Royal S. Copeland, president of the hospital, announced the gift of a completely furnished 300-bed annex to the hospital, by Charles M. Warner, president of the Warner Sugar Refining Company. A six-story building immediately adjoining the hospital building has been acquired for this purpose. This annex is to be used in caring for soldiers and sailors and will be ready for occupancy by August 1.

Meningitis Expert Goes to China.—Lieut. Peter K. Olitsky, Medical Corps, U. S. Army, and of the scientific staff of the Rockefeller Institute for Medical Research, on permission granted him by the Surgeon-General, sailed from Vancouver, April 11, for China, in response to a cabled request received by the institute from the colonial secretary at Hong Kong for assistance in a local outbreak of epidemic meningitis. Dr. Olitsky is to advise the Hong Kong government concerning the control of the disease, especially in the preparation of an effective serum and the institution of other therapeutic and prophylactic measures.

Clinical Facilities for Cruiser and Transport Force.—Through the mayor's committee on national defense, the commander of the Cruiser and Transport Force, United States Atlantic Fleet, has sought and obtained access to the clinics and hospitals of greater New York for the professional experience of medical officers of the cruisers and naval transports. A number of the hospitals of the city have announced hours at which clinics are held. The Society for the Advancement of Clinical Study in the New York Bureau of Clinical Information, New York Academy of Medicine, 17 West Forth-Third Street, is prepared to give daily information of operations, hours and operators at the various hospitals throughout the greater city.

Protest Against Reorganization of Health Department.—Protests against the abolition of certain bureaus in the New York Health Department that have been shown to be essential to effective public health work continue to pour in from many quarters. Among those who have written letters to Mayor Hylan are Dr. William H. Welch, president of the Maryland State Board of Health and director of the school of hygiene and public health at Johns Hopkins University; Dr. William A. Evans, former commissioner of health of Chicago; Dr. Charles J. C. O. Hastings of Toronto, Canada, president of the American Public Health Association; Peter H. Bryce, chief medical officer, Department of Interior, Ottawa, Canada; Charles E. A. Winslow, professor of public health at the Yale University Medical School; Dr. Charles V. Chapin, superintendent of public health of Providence, R. I., and many others prominent in public health work. The protest against the proposal to abolish the bureau of public health education is especially emphasized by these authorities on public health matters. The Surgeon-General's Office has entered a protest and there has been a rumor afloat that the government would interfere if the efficient heads of bureaus were removed and inferior or untrained men and women employed. Surgeon-General Blue, in his letter says, "In the larger centers and industrial communities, health problems in their relation to industries have never constituted a more important consideration than in these days when increased production along many lines is absolutely essential. The conservation of health not only among the fighting forces, but in the entire civil population as well, is a war time problem of greatest moment. The day has passed when inferior men can do the work, and skilled men in sanitation and public health science are necessary." A statement issued, April 26, by James E. McBride of the municipal civil service commission contains recommendations made by Dr. S. Josephine Baker for the reorganization of her bureau along more economical lines, whereby she proposes a saving of $105,000. The abolition of the district offices in the borough of Queens is recommended on the ground that the work in that borough was carried on effectively before those offices were established. Other economies, the recommendations state, could be effected by a reorganization of the nursing service and a reduction in the clerical work done by nurses, and part time inspectors could be required to work three and one-half hours a day instead of three hours.

OKLAHOMA

Tuberculosis Survey.—April 1, the Oklahoma Association for the Prevention of Tuberculosis began a series of public health surveys in the larger towns of the state to secure reliable data concerning communicable diseases, particularly tuberculosis. The towns to be included in the survey are Oklahoma City, Tulsa, Muskogee, Enid, Shawnee, Bartlesville, Ardmore, Chickasha and McAlester. It was found last fall that the association was much handicapped in its work by the lack of information concerning health matters, hence these surveys were instituted. The information obtained by the surveys will permit of the inauguration of satisfactory measures for safeguarding the public health and a more comprehensive program with relation to tuberculosis. The surveys are in charge of M. P. Horowitz, of the department of biology and public health, Massachusetts Institute of Technology, and Dr. Gayfree Ellison, Norman, professor of bacteriology and hygiene of the University of Oklahoma, assisted by members of the executive and nursing staff of the state tuberculosis association, as well as by the staff of the state board of health and the board of agriculture. The surveys will be continued all summer and to the end of September.

PENNSYLVANIA

Personal.—Dr. Samuel P. Longstreet has been appointed director of the Scranton Health Department.——Dr. Roger P. Batchelor has been appointed superintendent of the Palmerton Hospital, succeeding the late Dr. John W. Luther.——Dr. Walter W. Seibert of Easton has been elected president of the Lehigh Valley Homeopathic Medical Society.——Dr. Florence L. Marsh of Mount Pleasant celebrated her fiftieth year in the practice of medicine, having graduated from Jefferson Medical College in 1868.

Philadelphia

Naval Hospital Provided.—In the program to build fifteen temporary naval hospitals approved by the house of representatives, two will be located in Philadelphia, one of them being on League Island.

Fund to Fight Mosquitoes.—The state department of health has been granted $75,000 by the state commission of the National Council of Defense to fight mosquitoes in the vicinity of Hog Island and League Island.

Public Health Day.—Wednesday, May 1, Public Health Day was celebrated by a great public health meeting at the academy of music. Dr. William W. Keen presided and addresses were made by former President W. H. Taft, Dr. Alice Weld Aallant, Dr. James M. Anders and Dr. Wilmer Krusen, chief of the department of public health and charities. This meeting was under the auspices of the College of Physicians, the county medical society, the Child Federation, the Pennsylvania Society for the Prevention of Tuberculosis, the City Club, the board of education, the board of recreation and the city health department.

Personal.—Dr. Ross B. Cobb has been appointed a city physician in the bureau of charities at a salary of $720 a year.——Dr. Ida L. Dunmoyer has been made assistant physician in the bureau of charities at a salary of $1,000 a year, and Dr. Alma H. Hinman has been appointed clinical physician in the bureau of charities at a salary of $900.——Dr. Samuel McClintock Hamill addressed the committee conference at its annual meeting at the City Club, Monday, April 22, on "What Philadelphia Can Do and the Duty of the City in Child-Saving."——Dr. H. Augustus Wilson has resigned the chair of orthopedic surgery in the Jefferson Medical College. Dr. Henry W. Stelwagon has resigned from the chair of dermatology in Jefferson Medical College. Both resignations are to take effect at the close of the present college year.——Dr. George A. Meeker has been appointed dean of the postgraduate school of the University of Pennsylvania.——Dr. Paul J. Pontius was elected a member of the board of directors of the Philadelphia County Medical Society, to fill the unexpired term of Dr. J. Norman Henry, resigned.

RHODE ISLAND

Relief Plans Outlined.—At a meeting of the Rhode Island Medical Society in Providence, March 20, Dr. N. Darrell Harvey, after giving an account of the work of the Rhode Island Red Cross Relief Unit, Halifax, N. S., last December, detailed the proposed plans for effective emergency relief work, which could be given Providence in the event of a similar disaster. The city is divided into eight precincts, in each of which two physicians are assigned to duty. Provision is made for keeping records of all patients treated, and for a house-to-house canvass by social service workers and nurses. The available amount of medical and surgical supplies is ascertained and also the amount to be obtained from the department stores for relief work. Nurses, physicians, stretcher bearers, and orderlies have been enrolled, and automobile trucks and buildings suitable for hospital purposes have been secured.

SOUTH CAROLINA

County Tuberculosis Camp.—The work preliminary to the establishment of Camp Alice, Sumter County Tuberculosis Camp, which was made possible by Mr. H. J. Harby's donation of $10,000 in cash and a site for the institution, has been practically completed. The work of construction will be begun as soon as the site can be cleared.

Personal.—Dr. Skottowe B. Fishburne, city health officer of Columbia, has sent in his resignation, which took effect, May 1. Dr. R. T. Jennings has received a temporary appointment as his successor.——Dr. Baxter Haynes, Spartanburg, has entered on his duties as health officer of Spartanburg County.——Dr. Charles E. Low, Spartanburg, formerly health officer of Spartanburg County, has resigned to accept the position of director of health in Wilmington, N. C.

CANADA

University News.—About sixty young doctors just graduated from the University of Toronto will join the Canadian Army Medical Corps within the next month. Many of the third and fourth year men have already offered themselves for service on destroyers and elsewhere.——Queen's medical faculty are making preparations with regard to the new military service regulations. Men liable for service under the act are being placed in the C. A. M. C. for service in Canada, and will be allowed to continue their studies next fall if conditions permit. A summer session will likely be held to provide for fourth-year men graduating in the fall.——It is reported that the students of Laval University, Montreal, are joining the colors in large numbers.

Cod Liver Oil.—According to *Commerce Reports*, large quantities of cod liver oil are produced in Newfoundland as a by-product of the fishing industry. The quality of the oil heretofore however, has been said to be inferior to that prepared in Norway. In 1910, the government procured an expert from Norway and a law was passed in 1916 requiring refiners of cod liver oil to take out licenses. The product has been much improved and it is said oil as good as that produced in Norway is now obtainable from Newfoundland. The production of refined oil has increased considerably in the past few years. In 1913-1914, the amount of refined oil exported was 26,218 gallons, in 1914-1915 it was 47,170 gallons, and in 1915-1916 it was 142,637 gallons. The amount of common oil exported during those years was in excess of a million gallons a year, and a greater output of refined oil only awaits a market.

Saskatchewan Medical Legislation.—It has been decided in the province of Saskatchewan to place the medical men under their own act, the medical profession act, and the irregular practitioners under the act respecting drugless healers. Under the latter, the commissioner of public health shall admit on the register of drugless practitioners and issue licenses to every person registered under the osteopathic act at the time this act comes into force, whose fees at such time are fully paid. Such persons shall not be restricted in the practice of their profession to a greater degree than they are restricted by the osteopathic act. The commissioner of public health shall also admit any person who has been certified to by the registrar of the University of Saskatchewan as having satisfactorily passed the examination for drugless practitioners and who produces satisfactory evidence of his identity as being the person certified, as well as evidence that he is 21 years of age, and is of good character, provided that such person shall be restricted to the practice of the method of treatment cited in his license. A drugless practitioner may use words or symbols to designate his calling, and may use the title, "doctor" or "physician," provided it is used in connection with words indicating that he is a drugless practitioner, or he may adopt the title "manipulative surgeon." Otherwise, he shall not use the letters "M.D.," or the prefix "Dr.," or the term "doctor" or "physician" or "surgeon," or the words "Doctor of Medicine," or "physician and surgeon" in connection with his name, nor shall he by advertisement, announcement or otherwise represent himself as a physician or surgeon.

Personal.—Lieut.-Col. James J. Fraser, D. S. O., Walkerton, Ont., has returned to Canada on leave from overseas service. Colonel Fraser went over as a captain, but has since gained his promotion, and also D. S. O., having been mentioned in despatches three times.——Major George F. Boyer, Toronto, who has been overseas with the University of Toronto Base Hospital, has returned. He served at Saloniki and later at Shorncliffe, Ramsgate and Buxton.——Dr. O. R. Avison, president of the Severance Union Medical College at Seoul, Korea, is on a visit to Toronto. Before going to Korea twenty-five years ago, Dr. Avison practiced in Toronto.——Major Alexander Mackay, Toronto, who has been overseas at the Ontario Military Hospital, Orpington, England, has been appointed inspector of prisons and hospitals for the insane and other charitable institutions in Ontario, succeeding the late Robert W. Bruce Smith.——It is understood that Capts. Frank S. Park and Walter R. W. Haight, Toronto, who were taken prisoners by the enemy at Zillebeke in 1916, have been released in a recent exchange of prisoners.——It is announced that Dr. Alfred Thompson, Dawson, elected a member of parliament for the Yukon, will resign his position as medical superintendent of the hospital for returned invalided soldiers.——Col. William B. Hendry, Toronto, who has been consulting with the University of Toronto authorities as to the university base hospital in England, has returned overseas.——Col. James A. Roberts, Toronto, who went overseas three years ago in command of the University of Toronto Base Hospital, has recently been appointed assistant medical director of services in London, England.——Capt. George Ewart Wilson, Toronto, who served overseas nearly three years with the University of Toronto Base Hospital, is now in Toronto, and has been appointed to the military section of the Toronto General Hospital, under Col. Alexander Primrose.——Dr. Clarence M. Hincks, Toronto, has been appointed secretary and assistant medical director of the Canadian National Committee for Mental Hygiene, a new organization just formed in Ottawa.——Dr. Agatha Doherty, Toronto, is junior surgeon on the staff under Dr. Aldrich Blake of the hospital for women, London, England. Dr. Doherty is also lecturing at the Queen Charlotte Hospital, and is connected with the Women's Compensation Board for the Marleybone district.

GENERAL

Bequests and Donations.—The following bequests and donations have recently been announced:

An addition to the Good Shepherd Hospital, Syracuse, N. Y., for the care of wounded American soldiers, and two scholarships in the Harvard Medical School, by the will of Mrs. Elizabeth C. Farnham of New York City.

Sanitary Conference.—A conference of health and sanitation experts of the South was held at Birmingham, Ala., March 25 and 26, under the presidency of Dr. Watson S. Rankin, Raleigh, N. C. The principal subjects discussed were soil pollution and its prevention, the diseases arising from soil pollution, including typhoid fever, dysentery, and hookworm disease, and compulsory sanitary ordinances.

For Poliomyelitis Work in South Africa.—At the request of the South African Institute for Medical Research, the Rockefeller Institute for Medical Research has arranged with the Vermont State Department of Health to release Dr. Edward Taylor for temporary service in Johannesburg, in order that he may advise the government there in respect to an epidemic of poliomyelitis prevailing in that region. Dr. Taylor sailed from New York, April 20.

Eighth Pan-American Medical Congress to Meet at Buenos Aires.—The official notice has been received by the authorities of Argentina from the permanent international committee that, according to the unanimous vote at the seventh congress, held at San Francisco, the next meeting will convene at Buenos Aires. The Academia de Medicina has been empowered to appoint the committee of organization for the celebration of the congress, the Eighth Pan-American Medical Congress, in 1919.

District Association Meeting.—The spring meeting of the Iowa and Illinois Central District Medical Association was held at Rock Island, Ill., April 11. After the presentation of clinical cases, Dr. Henry Albert, Iowa City, Iowa, gave an illustrated talk on "Animal Parasitic Infections Increased by War Conditions." Dr. Clifford U. Collins, Peoria, Ill., presented a paper on "Parotitis as a Postoperative Complication," illustrated by lantern slides, and Dr. David S. Fairchild, Clinton, Iowa, gave some reflections on medical economics.

National Tuberculosis Association Meeting.—In the *Bulletin* of the National Tuberculosis Association for April, it is announced that the name of the Nation [illegible] iation for the Study and Prevention of Tuberculo [illegible] an ed [illegible] the National Tuberculosis Association. The fourteenth annual meeting of the organization will be held in Boston, June 6, 7 and 8, 1918. The Copley-Plaza Hotel will be the place of meeting, and on the evening of the first day there will be a meeting of the American Sanatorium Association. The preliminary program is being sent out from the executive offices, 105 East Twenty-Second Street, New York. The new address of the association is 381 Fourth Avenue, New York. The association has recently been incorporated. A committee on federal legislation has been appointed, and also a committee of five clinicians to act for the association in cooperation with the military and naval authorities in government plans for caring for soldiers and sailors suffering from tuberculosis.

Prevention of Blindness.—The third annual report of the National Committee for the Prevention of Blindness, covering the calendar year 1917, shows that, in the thirty-one state schools for the blind in the United States, there was a total of 2,961 pupils blind from ophthalmia neonatorum. In addition, there were 375 pupils in classes for the blind in public schools, making a total of 3,336 pupils blind from this cause. Three states, Delaware, Minnesota and North Carolina, were added to the list of states having laws for the prevention of ophthalmia neonatorum. During the year, the committee undertook more active work in the prevention of eye injuries in the industries, of which there were about 200,000 among the two million nonfatal accidents in industrial occupations, or 10 per cent. of the total. Approximately 15,000 persons in the United States are blind as the result of industrial injury. The committee has carried on its campaign of education in prevention by lectures, exhibits, and publications of various sorts, as well as by personal work of the officers and others of the committee. During the fifteen months from October, 1916, to the end of December, 1917, the expenditures of the committee were $22,375, and there was a balance of $6,543.03 on hand to begin the work of the new year.

FOREIGN

Medical School in French African Colony.—Provisions have been made for a medical school at Dakak in French West Africa. The aim is to train native practitioners and midwives.

Price of Paper in France.—The *Paris Médical* cites a recent official publication which mentions that while paper in the second quarter of 1914 cost 27 francs, in 1915 the same amount cost 31.2; in 1916, 55.65; in 1917, 81, and in January, 1918, 145, with a jump to 160 the following month.

Deaths in the Profession Abroad.—**H. Mallet**, professor of pediatrics at the University of Geneva, aged 43.——**P. M. C. Blarez**, professor of chemistry at the University of Bordeaux and author of over 200 works on pure and applied chemistry, aged 66.——**E. T. Speyr**, a leading Swiss ophthalmologist, and writer on his specialty, aged 50.——the *Nederlandsch Tijdschrift* mentions the death of **O. von Sicherer**, professor of ophthalmology at the university of Munich, and of Prof. **A. Wossidlo**, a urologist of Berlin, aged 63.

CENTRAL AND SOUTH AMERICA

Lepers Escape from Colony.—On account of dissatisfaction with the food furnished them, 300 lepers segregated in the colony at Agua de Dios near Bogota, Colombia, escaped from their keepers, and scattered to various parts of the Santander district.

Porto Rico's Roll of Honor.—The *Boletin de la Asociacion Medica* gives the names of fourteen physicians who have responded to the call of the Surgeon-General and joined the Medical Corps of the American Army. Some have given up a good practice or remunerative position. Those from San Juan are Drs. Laugier, Font, Lippitt, Igaravidez, Glines, Casellas and Ferrer; from elsewhere in the island, Drs. Benitez, De Quevedo, Caparro, Mejias, Janer and Crescioni.

Semicentennial of Bahia Medical Journal.—The *Gazeta Medica da Bahia* celebrates its fiftieth anniversary by issuing a special number of 364 pages. Bahia is on the seacoast of northern Brazil and its university dates from 1808. Among the collaborators on the *Gazeta* are Profs. P. Pereira, C. Fraga, C. de Andrade, and Drs. O. Torres, A. de Britto and O. Freire—all authorities on various phases of tropical medicine. This special number contains reviews of the incidence of beriberi, malaria, trachoma, and tropical and general diseases at Bahia during the last half century.

Leprosy in Porto Rico.—Dr. J. A. Diaz presents in the journal issued by the Porto Rico Medical Association the report of a committee appointed to investigate conditions in regard to leprosy in Porto Rico. The committee visited Cabras Island, which is set apart for the leper colony. The island is so sandy and rocky that there is no chance to raise vegetables or flowers. The colony consists of fifteen leper women and twenty-six leper men, with two servants and a resident practitioner. The only drinking water available is rain water, with a central arrangement for collecting it. The passage by small boats to the island is a dangerous one. Several persons have been drowned trying to make the trip, including one government employee. The committee recommends removing the leper colony from Cabras Island to some remote but fertile portion of the mainland of Porto Rico, and applying to the care and treatment of the lepers the principles of a modern sanatorium for tuberculosis, instead of leaving them in this hopeless isolation.

CORRECTIONS

Disloyalty Charge.—In The Journal, April 27, under medical news, Indiana, appeared an item concerning the retirement of Dr. Frederick W. Krueger from the Wayne County conscription board. Dr. Krueger writes that this statement is incorrect as he tendered his resignation to the board on account of local conditions, and that the resignation was accepted with sincere regret by Governor James P. Goodrich, who has expressed his absolute confidence in Dr. Krueger's loyalty.

Canadian Students Continue Studies.—In The Journal, April 13, under medical news, Canada, it is stated that the fifth year medical students of McGill University will dispense with their vacation and study until autumn in order to be able to go overseas with the Canadian Army Medical Corps. The registrar of this school writes that this item is incorrect as special courses of this nature are conducted only at the urgent request of the military authorities, who up to this time have made no request for such a course this year.

Death of Medical Officer.—In The Journal, April 27, 1918, a picture and a notice of the death in the service in France of Lieut. Julian Neal Dow, M. R. C., of Arcola, Ill., appeared. His parents reside at Neoga, Ill., and the information of his death came from apparently official sources, his parents furnishing the photograph on our request. The report of his death was an error, according to the Chicago *Tribune*, of the same date, April 27, which says that a cablegram was received stating that Lieutenant Dow was wounded, but not *killed*, and is now a prisoner in Germany.

PARIS LETTER

Paris, March 28, 1918.

The Antiseptic Power of Vincent's Boric Acid-Hypochlorite Mixture

Dr. Bazin demonstrated recently at the Society of Biology the results of comparative studies between the antiseptic power of the boric acid-hypochlorite mixture and that of the tincture of iodin and of iodoform. The first researches in vitro have shown that to inhibit the development of bacteria in a given bouillon culture required the use of 3 gm. of Vincent's mixture, while to check the cultures in the same bouillon, 10 gm. of tincture of iodin and 25 gm. of iodoform were required. To study the comparative toxicity of the several products, Bazin introduced them into the peritoneal cavity of guinea-pigs. Swabbing this cavity with tincture of iodin, or the introduction into its interior of a weak dose of iodoform, caused the death of the animal, while the mixture of Vincent caused only a slight reaction. In cutaneous wounds and other superficial wounds suppurating after infection with dirt, the tincture of iodin and Vincent's mixture seemed to have equal power; in muscular wounds soiled with dirt the mixture of Vincent showed a notable superiority. In wounds of the bones, the mixture showed great superiority over the tincture of iodin. As to iodoform, it showed always a very notable inferiority.

Antityphoid and Paratyphoid Vaccination of Native Troops from New Caledonia

At the last meeting of the Académie de Médecine, Drs. Guy Laroche and Mazet stated that the contingents of the black race had not been subjected as yet to antityphoid vaccination because of the infrequency of typhoid among the adults of these people; hence they feared that the reaction would be too severe. Nevertheless, last year they had occasion to vaccinate a contingent of Canaques following an epidemic of typhoid, which, in the same battalion, did not attack the vaccinated whites but only the unvaccinated

Canaques. Two inoculations of 1 and 2 c.c. were made with an eight day interval. The vaccine used was the heated vaccine of the typhoid and paratyphoid bacilli. (New Caledonia in the Southern Pacific belongs to France.) Only slight reactions occurred, although the Canaques presented the majority of the conditions in the presence of which we hesitate to vaccinate: malaria, dysentery, filariasis, etc. Not only were there no accidents, but in the majority of cases the injections were tolerated better than they are by the Europeans. The lesser intensity of the reaction was probably due to the fact that the nervous system of the black races is much more calm than that of the white race. This observation proves that in the presence of analogous cases among colored people, there is no need to hesitate to practice antityphoid and paratyphoid vaccination.

Medical Students Serving in the Navy

The minister of marine has decreed that medical students serving in the marine in the capacity of seaman nurses and *titulaires* of one, two or three inscriptions, who have not been able to enter the preparatory school of medicine at Bordeaux because of their service with the colors, which has prevented them from completing their medical course, are to be sent to Bordeaux to pursue the prescribed complementary course at the preparatory school of medicine under officers of the corps de santé de la marine.

American Aid

The president of the republic recently received Mr. Henry P. Davison, president of the war committee of the American Red Cross, accompanied by Major Perkins, secretary-general, who had been presented by Mr. Sharp, the United States ambassador. The president extended to Mr. Davison his heartiest thanks and warmest felicitations for the valuable assistance rendered by the American Red Cross to the allied armies and particularly to France. He added that he had witnessed again at the Courneuve the great services rendered to the victims of the recent catastrophe.

Mr. Davison, at the hotel Ritz, had previously received the representatives of the Paris press. After explaining the nature of the American Red Cross, he detailed the enormous development of that institution since its reorganization a year ago. The membership has increased from 200,000 to 23,000,000, with 75,000 local chapters throughout the United States. Mr. Davison outlined the work undertaken by the American Red Cross in Europe, and insisted that it was not a work of charity, but of love and affection. In order to realize the materialization of the plans outlined, a new public subscription would be launched in the United States next May, and it is estimated that as large a fund at least, if not larger, will be secured as was obtained by the same means last year, over 500,000,000 francs.

Mr. Davison has left for the American front. He will visit some of the Red Cross centers in France and then he will proceed to Italy.

Interallied Food Conference

A scientific interallied food conference of professors from the French medical schools, and English, American, Italian and French experts, convened, March 25, at the Faculté de Médecine de Paris under the presidency of M. Victor Boret, minister of agriculture and food commissioner. In his opening address the minister outlined the object of the conference, namely, to study the conditions permitting of making the best use possible of the limited resources at the disposal of the Allies, sustenance not only for man but also for animals. The chemical composition of foods and their equivalents will serve as a basis for this work. Following the minister's remarks, the delegates outlined the program for their work, and set to work at once.

Institution of a Fund for Social Study

Two Americans, Miss Eleanor Chalfant and Mrs. Walter S. Mitchell, have donated the sum of 5,000 francs as a fund to be given to some French woman who has distinguished herself in social service work, enabling her to take a trip to the United States in order to gather information at first hand. Dr. Charles White of the American Red Cross has been entrusted with the carrying out of this plan, which will be supervised by a committee of patronage including Professor Letulle, member of the Academy of Medicine, and Senator Léon Bourgeois, president of the Alliance for Social Hygiene.

Death of Dr. Camille Sauvage

Dr. Camille Sauvage, aged 44, professeur agrégé de la Faculté de médecine de Paris and accoucheur des hôpitaux, is dead. Since the first day of mobilization he has been on active duty in the zone des armées, first in charge of an ambulance and then of a large hospital. He was active for two and a half years; then worn out by fatigue he was forced to take to his bed. After a lengthy convalescence, he reported for service again, but just then he became ill again and died. Sauvage was the author of a number of important publications. Of special note are those on rupture of the uterus and on syphilis and its bearing on reproduction.

BUENOS AIRES LETTER

Buenos Aires, March 24, 1918.

Infant Mortality in Buenos Aires

According to statistics published recently by Dr. E. R. Coni, the infant death rate during the ten years ending with 1907 was 31.1 per cent. of the total mortality. In the decade following, ending with 1917, the proportion was 36.4 per cent. By infant mortality he means the deaths of children less than 2 years old. The Argentine Sociedad de Pediatria is to discuss this increasing infantile death rate at its next meetings.

Bibliographic Index of Medical Works in Argentina

The Circulo Medico of Rosario issued last year an alphabetical index of all the medical works published in Argentina up to the end of 1916.

Tuberculosis Death Rate at Cordoba

The mortality from tuberculosis in this large city of northern Argentina has shown a progressive increase in recent years, having risen from 30 per ten thousand inhabitants in 1897 to 43.8 in 1916. The Cordoba province is sought by the tuberculous elsewhere on account of its climate, but at the same time there is an increase among the older residents.

Pituitary Body and Polyuria

In a recent publication, Drs. Houssay and Romaña assert that the so-called pituitary polyuria is dependent on lesions of a zone in the cortex adjoining the pituitary, and extending from the pons to the chiasm. They witnessed the development of polyuria in young dogs after complete removal of the pituitary. This zone in the brain seems to be responsible for the polyuria, but it is impossible to say whether the posterior lobe is or is not included in this zone.

Venereal Granuloma

Considerable research has been done on venereal granuloma in South America, particularly in Brazil. It is comparatively rare in Argentina. Roffo with some of his co-workers (Nin Posadas, Ghiso, Zarate, Farini and Zerbini) have described several cases, curing them all completely by the Viana method of treatment, namely, intravenous injections of a 1 per cent. solution of tartar emetic, sterilized by filtration.

Marriages

Lieut. Frederick Efner Wrightman, M. R. C., U. S. Army, Sabetha, Kan., to Miss Rosina Tinsley of Wilkes-Barre, Pa., at Washington, D. C., recently.

George Eugene Dodge, Tucson, Ariz., formerly of New York, to Mrs. Mabel R. Kerrigan of Tucson, Ariz., April 9.

Lieut. Gerald Spencer Shibley, M. R. C., U. S. Army, New York, to Miss Florence Isabel Miller, recently.

Charles Bernard Pritchett, Danville, Va., to Miss Shepherd Leak, Wadesboro, N. C., April 17.

James Alfred Fisher, Clayton, N. J., to Miss Janet Ackerman of Ashbury Park, N. J., April 9.

Haynes Jordan Freeland, Rocky Ford, Colo., to Miss Mary Osgood Parker of Indianapolis, April 9.

John Conger Bryan, New York, to Mrs. Margaret A. A. Rumsey, at Trenton, N. J., March 28.

Ruffin Alexander Paine, Denver, Colo.; to Miss Imogene Norris, New Orleans, La., April 17.

Colin Luke Begg, New York City, to Miss Susanne Confere of New Orleans, April 10.

Voyle Abrams Paul to Miss Ada G. Stark, both of Stamford, Conn., March 28.

Deaths

Ephraim Fletcher Ingals, Chicago, died at his home on April 30 from angina pectoris. Dr. Ingals was born in Lee Center, Ill., Sept. 29, 1848, and graduated from Rush Medical College in 1871. He was a nephew of Ephraim Ingals, for many years professor of materia medica and therapeutics in Rush Medical College, and it was under the tutelage of his distinguished uncle that Dr. E. F. Ingals took up the study of medicine. In 1871, after his graduation, Dr. Ingals became assistant professor in materia medica from 1871 to 1873; lecturer on diseases of the chest and physical diagnosis, 1874; professor of laryngology from 1883 to 1890; professor of laryngology and practice of medicine from 1890 to 1893; laryngology and diseases of the chest from 1893 to 1898; professor of diseases of the chest, throat and nose, and comptroller since 1898. He also was professor of diseases of the throat and chest in the Northwestern Woman's Medical School from 1879 to 1898; professor of laryngology and rhinology in the Chicago Policlinic since 1890, and lecturer on medicine in the University of Chicago since 1901. Dr. Ingals was one of those who were instrumental in arranging the affiliation of Rush Medical College with the University of Chicago, especially in convincing President Harper of the university of the importance of linking medical education with the university in order to make progress. The importance of his connection as comptroller of Rush Medical College with the life of the medical school cannot be overestimated. The West has had few men who have worked so actively and efficiently for the advancement of scientific medicine.

EPHRAIM FLETCHER INGALS, 1848-1918

Dr. Ingals was a Fellow of the American Medical Association, being trustee from 1893 to 1896, and from 1900 to 1903 a member of the American Laryngological Association, the American Laryngological, Rhinological and Otological Society, the American College of Surgeons, the Chicago Institute of Medicine, the Chicago Pathological Society, the American Climatological Association and the American Medical College Association. He was chairman of the section of laryngology of the Pan-American Medical Congress in 1883. He was author of "Diseases of the Chest, Throat and Nose," the fourth edition of which appeared in 1900, and of many articles and monographs on the same subject. His most recent literary work, entitled "Angina Pectoris," was published in THE JOURNAL for April 6. In this he describes, in great detail, his own experience with this disease. During his severe and extended illness he displayed remarkable courage and bravery. His discussion of the condition reveals a sustained, clear, scientific consideration and judgment under most trying conditions.

Moses H. Waters, Terre Haute, Ind.; New York Homeopathic Medical College and Hospital, New York, 1865; aged 37; a member and formerly president of the Indiana Institute of Homeopathy; senior at the American Institute of Homeopathy; a veteran of the Civil War; formerly president of the Terre Haute Board of Health; general surgeon of the Morton Post Grand Army of the Republic; died at his home, April 14, from heart disease.

Lloyd Jones Belt, Millen, Ga.; New York University, New York, 1885; aged 61, formerly a Fellow of the American Medical Association; a member of the Medical Association of Georgia; formerly vice president of the Screven County Medical Society; a member of the State Commission on Tuberculosis; formerly president of the Jenkins County Medical Society; died at the Savannah, Ga., Hospital, April 9, from heart disease.

Lieut. Hugh Tate Moore, M. R. C., U. S. Army, Wilmington, N. C.; Tulane University, Medical Department, New Orleans, *1910*; aged *31*; a Fellow of the American Medical Association; a specialist in diseases of the eye, ear, nose and throat; a member of the medical staff of the Base Hospital at Camp Kearny, San Diego, Calif.; died, April 8, from mercuric chlorid poisoning, the drug being taken by mistake for calomel.

Capt. Peter L. S. Keough, M. R. C., U. S. Army, Pawtucket, R. I.; College of Physicians and Surgeons, Baltimore, 1912; aged 28; formerly a member of the Medical and Chirurgical Faculty of Maryland; formerly assistant superintendent of the Maryland State Hospital; and a member of the staff of the Memorial Hospital, Pawtucket; died while on active service at Camp Sherman, Ohio, April 15, from pneumonia.

Augustus Chapman Walker, Cambridge, Mass.; Harvard University Medical School, *Boston, 1866*; aged 84; formerly a Fellow of the American Medical Association; a member of the Massachusetts Medical Society; a veteran of the Civil War; formerly a member of the State Board of Registration and Pharmacy; died at his home, April 5, from arteriosclerosis.

Lieut. Abraham Lewis Bobrick, M. R. C., U. S. Army, New York; Long Island Medical College, 1917; aged *26; house surgeon* at the Harlem Hospital, New York, ordered to report at the Army Medical School, April 15, died at the Harlem Hospital, *April 17*, from streptococcus septicemia following an infection of the right forearm.

Robert Alexander Blackford, Martin's *Ferry*, Ohio; University of *Pennsylvania*, Philadelphia, *1899;* aged 51; a Fellow *of the American* Medical *Association;* director of *the* Martin's Ferry Hospital; formerly president of the Martin's Ferry Board of Education; died in the Martin's Ferry Hospital, April 12, from pneumonia.

Jacob Friedman, St. Louis; Washington University, Medical School, St. Louis, 1878; aged 61; a Fellow of the American Medical Association; professor of therapeutics and clinical medicine in the St. Louis University, School of Medicine; died in the Augustana Hospital, Chicago, April 13, from carcinoma of the colon.

Lieut. *Francis Virgil Frazier,* M. R. C., U. S. Army, Altamont, Mo.; University of Nashville, Tenn., Medical Department, 1911; aged *29*; a member of the Missouri State Medical Association; died from wounds received from a German bomb, while passing from one base hospital to another on the Belgian front, April *3*.

Perley G. Garlick, San Francisco; Hahnemann Medical College of the Pacific, San Francisco, 1903; aged 42; formerly associate professor of dermatology in the Hahnemann Medical College of the Pacific; a member of the American Institute of Homeopathy; died at his *home*, January 27, from ruptured aortic aneurysm.

George Baptie, Ottawa, Ont.; Trinity Medical College, Toronto, 1875; aged 72; professor of chemistry in Provincial Agricultural College, Guelph; formerly coroner of Ottawa; former president of the Ottawa Clinical Society, and Medico-Chirurgical Society; died at his *home*, January 5, from Bright's disease.

Albert V. Linton, Saginaw, Mich.; College of Physicians d Surgeons, Keokuk, Iowa, 1889; aged 53; formerly a llow of the American Medical Association; a member of Michigan State Medical Society; at one time coroner of ginaw County; died at his home, April 7.

Edward Mott Moore, Rochester, N. Y.; University of ffalo, Medical Department, 1874; aged 67; formerly a llow of the American Medical Association; a member of e American Surgical Society, and the American Academy Medicine; died at his home, April 5.

Charles F. Scattergood, Albany, N. Y.; Albany, N. Y., edical College, 1868; aged 74; local chairman of the ational Society of Chiropodists; and was a charter member d treasurer of the Albany division of the State Pedic ciety; died at his home, April 1.

Silvio Henry Von Ruck, Asheville, N. C.; University of llevue Hospital Medical College, New York City, 1899; ed 42; a Fellow of the American Medical Association; a ted authority on tuberculosis research; died in a hotel in w York City, April 8, from pneumonia.

James W. O'Connor, Elizabethwn. Ky.; Kentucky School of edicine, Louisville, 1889; aged 56; rmerly a Fellow of the American edical Association; a member of e Kentucky State Medical Assoation; died suddenly, January 30, om organic heart disease.

Isidor Samuel Leopold Bermann, ashington, D. C.; University of urzburg, Germany, 1878; aged 72; Fellow of the American Medical ssociation; a specialist in diseases the eye, ear, nose and throat; ed at his home, about April 6, om angina pectoris.

Edward Mortimer Boykin, harleston, S. C.; Medical College the State of South Carolina, arleston, 1905; aged 34; a mem r of the South Carolina Medical sociation; died at the Roper Hostal, Charleston, April 4, from eningitis.

Jesse A. Clason, Fond du Lac, Vis.; Missouri Medical College, St. Louis, 1884; aged 57; formerly Fellow of the American Medical Association; a member of the Wisconsin State Medical Society; died at his home, April 7, from heart disease.

James Horace Ingalls, Worcester, Mass.; Kentucky University, Medical Department, Louisville, 1904; ged 37; for several years connected with the Emergency Hospital, Worcester; died at his home, April 6, from pneumonia.

Merritt E. Proctor, Lake Placid, Y. Y.; Baltimore Medical College, 907; aged 35; a Fellow of the merican Medical Association; county health officer of Essex ounty; died at his home, April 4, from cerebral hemorrhage.

Maurice J. Silverman, New York; New York University, ledical Department, New York, 1892; aged 55; a Fellow of e American Medical Association; died suddenly while visitg a patient, April 11, from heart disease.

Selvy Andrey Bass, Wichita, Kan.; Hahnemann Medical ollege and Hospital, Chicago, 1881; aged 65; formerly a ember of the staff of Wichita Hospital; died at his home, pril 8, from heart disease.

James William Shaul, Los Angeles; University of Buffalo ledical Department, 1896; aged 47; a Fellow of the Amerian Medical Association; died at his home, February 21, om heart disease.

Edwin Huntington Bailey, Flint, Mich.; Detroit Homepathic Medical College, 1903; aged 37; a member of the lichigan State Medical Society; died at his home, April 4, om pneumonia.

William S. Throckmorton, Canonsburg, Pa.; Jefferson ledical College, 1865; aged 79; formerly a member of the Medical Society of the State of Pennsylvania; died at his home, April 5.

George Mill, Philadelphia; Medico Chirurgical College of Philadelphia, 1902; aged 41; a member of the Medical Society of the state of Pennsylvania; died at his home, March 7, from pneumonia.

Bernard Oscar Harris, Detroit; Detroit College of Medicine and Surgery, 1914; aged 23; a Fellow of the American Medical Association; died at his home, April 9, from pneumonia.

Charles F. Livengood, Boswell, Pa.; Baltimore Medical College, 1886; aged 53; a Fellow of the American Medical Association, died suddenly at his home, March 26, from paralysis.

P. Louis Nagin, New York; Long Island College Hospital, Brooklyn, 1914; aged 32; formerly clinic physician of Gouverneur Hospital; died at the Rockefeller Hospital, April 5.

Thomas J. Deem, Parkersburg, W. Va.; Starling Medical College, Columbus, 1891; aged 50; died suddenly at his home in Vienna, April 3, from heart disease.

Died in the Service
LOST AT SEA
LIEUT.-COL. WILLIAM W. RENO, M. C., U. S. ARMY, 1873-1918
(See The Journal, April 20, p. 1182)

Charles C. Jolliffe, Hasbrouck Heights, N. J.; Kentucky School of Medicine, 1892; aged 69; died in the Hackensack Hospital, Hackensack, N. J., April 7.

Anthony P. Witting, Evansville, Ind.; Jefferson Medical College, 1879; aged 64; died at St. Mary's Hospital, Evansville, April 6, from pneumonia.

Irwin Hibbs, Brazil, Ind.; Kentucky School of Medicine, Louisville, 1854; aged 89; died at the home of his son, April 10, from senile debility.

Van Dyck McKelvey, Denver; Denver and Gross College of Medicine, Denver, 1910; aged 30; died at his home, April 4, from pneumonia.

John W. Reed, Beallsville, Ohio; Medical College of Ohio, Cincinnati, 1864; aged 77; died at his home, January 28, from bronchial pneumonia.

Norman Leslie Beale, Middletown, Del.; Atlantic Medical College, Baltimore, Md., 1909; aged 34; died at his home, April 7, from pneumonia.

Henry W. Boynton, Toledo, Iowa; Albany (N. Y.) Medical College, 1866; aged 80; died at his home, January 21, from cardiorenal disease.

Joseph B. George, Gainesville, Ga.; Medical College of the State of South Carolina, Charleston, 1890; aged 56; died at his home, April 5.

John H. DeWitt, Saugerties, N. Y.; Albany, N. Y., *Medical* College, 1863; aged 75; health officer of the town and village of Saugerties; died at his home, March 18.

James Buchanan King, Wyoming, Ohio; Miami Medical College, Cincinnati, 1885; aged 54; a member of the Academy of Medicine; died at his home, April 10.

Milton M. Catlin, Canton, Ohio; Western Homeopathic College, Cleveland, 1868; aged 72; died at his home, April 4, from pneumonia.

Gustavus Weems Petherbridge, Charlotte Hall, Md.; University of Maryland, Baltimore, 1866; aged 72; died at his home, March 9.

Lewis P. Walton, Atlanta, Ga.; Meharry Medical College, Memphis, Tenn., 1900; a colored practitioner; died at his home, April 4.

Frederick Veazile Hardwick, Boston (license, Massachusetts, 1904); aged 40; died at his home, April 9, from pneumonia.

A. R. Bowen, Tyro, Miss. (license, Mississippi, 1882); aged 69; died at his home, April 15.

Correspondence

TO THE CONSTITUENT ORGANIZATIONS OF THE AMERICAN MEDICAL ASSOCIATION

To the Editor:—May I address through The Journal, particularly the officers of constituent and component organizations of the American Medical Association? The necessity of securing an American army of physically efficient troops is of immediate fundamental importance to the United States. The initial steps toward this lie with and are dependent on the medical profession. The obligation is no longer limited to those appointed by governors to examine registrants, but has been, morally at least, imposed on the entire profession. It is axiomatic that our troops must be of finer fiber, stronger physique, better drilled and officered than an equal number of the enemy, that we may prevail. It therefore becomes the duty of every member of the American Medical Association to aid in securing soldiers of such physical stamina. In attaining this result the cooperation of physicians is confidently anticipated.

I conceive it to be the duty of the officers of constituent state medical associations and component county societies, the branches of the American Medical Association, to assist actively in carrying out the medical detail connected with the selective service law. The importance of medical examinations, careful in detail and accurate of record, cannot be exaggerated. Delays of induction, confusion in mobilization camps, and expenses to registrants and to the government have been entailed that could have been minimized and it is hoped may be avoided hereafter. If county medical societies will make a study, with discussions, of that part of the selective service regulations and their elaborations bearing on physical examinations, and will proffer assistance to examiners of local boards, who have doubled their daily duties by doing this work, the advantages to the service will be of inestimable value.

There are almost 5,000 local boards in the United States. One neglect or error, or delay of an examination or in recording its results in one day, multiplied by the number of registrants examined, arrives at a staggering total of possible mistakes. Errors in grouping men who pass before local and medical advisory boards result in the deferred classification of men who belong in Group A. This detains those who should be in service and sends others to duty in their place, or sends to camp men belonging in Group B because of a remediable defect not remedied, and no provision made except for their rejection, or, again, results in inducting into camp men falling into Group C, qualified only for special or limited service, when no call for such men has been issued.

There is a medical education to be had through the examination of many registrants, and the close professional contact with other medical men is of value, quite independent of other considerations. A weakness in our preparation for war has developed within the medical profession, not from incompetence nor from disloyalty nor from indifference, but rather from lack of experience in military matters. This has hindered somewhat the securing of a perfect execution of the medical examination of registrants—a fundamental necessity.

It was not possible to provide a medical advisory board for every local board, but one has been placed within the reach of nearly all. Their assistance should be invoked in all cases of doubt. The expense connected will be less than that arising from the induction of an unfit registrant into camp and his return home after being rejected.

Advisory boards, when not in full quota, should not hesitate to refer selected registrants whose condition requires special technical study to a qualified specialist.

The records in this office suggest a failure to appreciate the importance of accuracy. Nature does not come to the examiner's assistance, but he must decide the registrant's future unaided. Indirectly, he is thus determining his country's safety. District boards of appeal may no longer conduct a medical examination, but appeal cases on physical grounds should be determined by the findings of local and medical advisory boards. This throws additional responsibility on these boards for painstaking examinations and for full and clearly stated records.

County medical societies could not more profitably occupy one or more meetings than by having examiners of registrants prepare papers on the selective service regulations pertaining to the examination of registrants, for discussion by members. Officers of state societies could provide for a session to be given over to the study of this work, and the program in many sections of the American Medical Association, at its June meetings, might very profitably devote time to its discussion. In this way the physical examination of registrants may be perfected and our Army strengthened immediately. From the exact recording of such examinations, sociologic data of great value will be obtained.

Hubert Work, Major, M. R. C., Washington, D. C.
Medical Aide to the Provost Marshal-General.

NUTS AS A FOOD SUPPLY

To the Editor:—The editorial on "Peanuts as Food" (The Journal, March 23, 1918, p. 850) is in line with progress. More, however, may be said to advantage. It is a rule in economics that people do not make an effort toward filling a need until the need is felt. The American Indians used a large number of plants that have not as yet been cultivated systematically for the general food market. Eventually civilized man may employ most of the things that the Indians ate. Man began to cultivate the annual plants that bring prompt return for his labors, and this he is likely to continue to do by preference until he comes to understand that nut bearing trees give a larger yield per acre at lesser expenditure of time, care and expense than annual plant crops require, as a general rule.

Nuts may be divided into two general classes, first those that are rich in fats and nitrogen, members of the *Juglandaceae*, for exmaple; and next the starchy nuts, members of the *Castaneae*, for example. In some parts of the world, nuts already furnish a basic food supply, and perhaps 200 kinds of nuts are employed to greater or lesser extent for substantial food supply or as luxuries.

One reason that nut bearing trees have not been more generally cultivated lies in the idea that many years are required for their coming into bearing. This is not true of grafted nut trees of several kinds, some of which begin to bear in the first year after transplanting from the nursery or after top working of standing stock trees.

If any of the members of the American Medical Association care to take up the subject, they may wish to know that we have in this country two journals devoted exclusively to nut growing, the *American Nut Journal*, published at Rochester, N. Y., and the *Nut Grower*, published at Waycross, Ga. A number of responsible nurserymen who make a special feature of grafted nut trees advertise in these journals. Grafted nut trees of superior varieties are the only sort worth setting out if one has any sort of commercial proposition in mind.

Robert T. Morris, M.D., New York.

VENEREAL DISEASE IN THE ARMY: A SUGGESTION

To the Editor:—The lowest venereal rate of our regular army since the war with Spain was attained in 1916, when 91.23 men per thousand acquired such infection. Prior to the present war, the venereal rate in the home army of England was about 68; of Austria, 54; France, 28; Prussia, 19, and Bavaria, 15. At the present rate, the daily average of disability for duty through venereal disease in our entire army exceeds 30,000 men.

The success of the prophylactic treatment admittedly depends on its early use—the sooner the better. Under present regulations, the soldier is not provided with nor required to use prophylactic measures at the time of exposure.

because it is believed that his use would be an inefficient substitute for the official treatment that he receives when he returns to camp—an indefinite time after exposure.

But why regard his effort as a substitute for the official treatment? Why may not both be used? Since Reasoner's observations (The Journal, March 31, 1917, p. 973) have corroborated the clinical belief that soap alone destroys the spirochete of syphilis, it seems desirable to supply the soldier, if not with a complete kit, at least with a package of "prophylactic" soap, as a first aid packet; and to explain to him clearly both the method and the necessity for thorough use immediately after exposure. If the soap should be scented with some freakish perfume and colored with an anilin dye, the soldier's neglect to use it would probably be detected when he reports at barracks for the official treatment, in which event he should be penalized for disobedience of orders. If he fails to report and develops venereal infection, he is penalized under present regulations.

William T. Belfield, M.D., Chicago.

AS TO TOBACCO AND AVIATION

To the Editor:—The editorial on "The Physical Qualities of Aviators" (The Journal, April 27, 1918, p. 1229) condemns the use of alcoholics by fliers. I have noticed the same condemnation in other articles on the subject. On the face of it, it seems so plain that alcoholic narcosis has no place in so hazardous a task that it is almost unnecessary to mention the prohibition. Doubtless too, if a soldier were known to be under morphin narcosis, he would not be allowed to fly. Singularly enough though, the effect of tobacco narcosis on the aviator is never so much as mentioned. Cigaret narcosis has been conclusively proved to make the victim unsafe both to himself and to his fellow workmen, and by the law of business is not permitted to be indulged during working hours in factories. Can it be possible that such narcosis affects favorably the one who is to fly? Or does the cigaret user not apply for the position? Or is nicotin narcosis above and beyond discussion?

J. L. Tracy, M.D., Toledo, Ohio.

CONTINUOUS ELASTIC TRACTION IN THE TREATMENT OF CERTAIN FRACTURES OF THE PHALANGES

To the Editor:—There are occasional fractures of the phalanges in which it is difficult to hold the fragments in alinement by the methods usually employed. This applies especially to fractures of the phalanges of the toes, in which the fracture may be near the metatarsophalangeal junction and the toes are more or less deformed from the wearing of tight and narrow pointed shoes.

Some time ago (The Journal, Jan. 12, 1918, p. 78) I called attention to a new method of correcting the deformity in greenstick fractures of the forearm through the use of continuous elastic traction; and recently I have employed this principle in caring for two cases of complete fracture of the phalanges of the toes, in which roentgenoscopy showed that the fragments were not held in proper alinement by ordinary methods of treatment and there would be considerable angular deformity. In one case the fracture was within the web line, and angulation was marked and otherwise uncontrollable.

The following technic was employed: A long, well padded wooden splint, extending from the heel to about 1 inch beyond the toes, was applied to the plantar surface of the foot and held rigidly in place by adhesive plaster strapping and a bandage. One broad adhesive strip overlapped the anterior bodrer and ran along the entire under surface of the splint, over the heel, which was lightly padded, and continued 10 or 12 inches up the posterior surface of the leg; another adhesive strap about 2 inches wide embraced the posterior border of the splint and the heel and encircled the instep, while a third was somewhat loosely applied transversely at the level of the ball of the foot. A rubber band about one-eighth inch wide was cut at the center of one loop, and the resulting segments were fastened to the sides of the toe by a very narrow strip of adhesive plaster applied as a circular bandage. The free loop of the rubber band was then brought over the anterior end of the plantar splint under moderate tension and fastened securely by adhesive plaster, which embraced the loop and was attached for a considerable distance to the under surface of the splint. A gauze bandage was then applied from the toes to above the ankle.

In both cases in which this method was employed, the continuous slight elastic traction relieved the pain in a remarkably short time, the fragments were soon brought into almost perfect position, and the final results were equally pleasing.

Wesley Grove Vincent, M.D., New York.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

QUESTIONS OF INTEREST TO MEDICAL OFFICERS

To the Editor.—In The Journal last week I noticed a statement to the effect that medical reserve officers may now purchase equipment from the Quartermaster's Department. Is this law now pending in Congress or is it now effective? If so, shall I apply to the Quartermaster's Department of the nearest camp, that is, Camp Grant, for uniform and equipment? Can you give me an idea of the amount an officer's equipment would cost?

J. H. McMorries, M.D., Muncie, Ind.

To the Editor.—At the last meeting of our county medical society I heard several members say that they would join the Medical Reserve Corps if it were not for the injustice of being obliged to spend between $350 and $400 for uniforms. Our society meets again soon, and I wish you would give me some information which I could offer the members. Can a medical officer buy uniforms from the government instead of paying these robbing clothing men from $60 to $100 for an overcoat?

A. G. B., Minn.

To the Editor.—I have just sent in my application for a commission in the Medical Reserve Corps. I am anxious to know just what the emoluments are. I am married and have one child and an orphan nephew depending on me. A full explanation of the remuneration of the officers of the various ranks will be greatly appreciated.

E. A. R.

To the Editor:—Can you furnish me with the following information: 1. Has the Chamberlain bill been passed by Congress and signed by the President? This bill provides for extra allowance to commissioned officers for commutation, board, room, etc. 2. Has the bill passed providing that the government furnish to commissioned officers the necessary uniforms, equipment, etc., at cost price?

Morris B. Karatz, M.D., Chicago.

To the Editor:—Please indicate, roughly: (1) the approximate recompense of officers of the Medical Reserve Corps; (2) the cost of an ordinary service outfit.

R. B. Oleson, M.D., Lombard, Ill.

To the Editor:—I have just finished reading your editorial on the call for medical officers. In it you refer to a number of provisions which Congress has recently made to render it easier for men to enter the service. Among them you speak of the care of dependents, insurance and compensation, increased pay on foreign service, commutation of quarters, heat and light, moratorium on debts and leases of officers in the service, and purchase of equipment from the Quartermaster's Department. May I trouble you to supply me with information in regard to these points, or to advise me where I can obtain it, either in the columns of The Journal or elsewhere?

Thomas J. Harris, M.D., New York.

Answer.—*Purchase of Equipment.*—A bill was introduced into Congress to permit officers to buy their equipment from the Quartermaster's Department; however, before the bill came up for passage a general order No. 22, March 2, 1918, was issued stating that "orders heretofore restricting the sales of clothing and equipage to officers are hereby rescinded, except as to sales of woolen coats and breeches. Sales will be permitted only when articles are available and not needed for immediate issue to enlisted men." The Surgeon-General's Office has suggested to Medical Reserve Corps officers that they provide themselves with the following articles so as to be in readiness when called: 1 hat, service; 2 breeches, service olive-drab; 1 coat, service, O. D.; 1 leggins, leather, officer's; 2 pairs shoes, russet; 2 shirts, woolen, O. D.; 1 sweater, army; 1 hat cord, officer's; collar insignia and insignia of rank; 1 notebook, manifolding, pocket; 1 compass; 1 watch.

Officers may use their own underclothing, socks, handkerchiefs and toilet articles. Additional articles to the foregoing list can be purchased later. Provide yourself with 1 bedding roll, 2 army blankets, 1 sleeping pad (or two comforters); 1 mosquito bar, cot; 1 canvas basin, 1 canvas bucket, 1 collapsible candle lantern; 1 folding camp chair. These are sold by private dealers. If possible, provide yourself with a trunk locker, army pattern, sold by the Quartermaster's Department or private dealers. Your necessary mess equipment includes: 1 canteen, cavalry; 1 canteen strap, cavalry; 1 cup; 1 knife; 1 fork; 1 spoon; 1 meat can. You can purchase these from the ordnance officer at the nearest military post; or write to the Commanding Officer, Rock Island Arsenal, Rock Island, Ill., for the necessary vouchers and costs. Private dealers also sell them.

Cost of Equipment.—The estimated cost of a *complete* initial equipment of good quality is well within $200, and many officers have obtained it at a lower cost.

Dealers in Uniforms.—The following dealers in uniforms have advertised in The Journal, and so far as we know have given satisfaction to those purchasing equipment from them: Sigmund Eisner Company, Red Bank, N. J.; Kahn Tailoring Company, Indianapolis; Jacob Reed's Sons, 1424 Chestnut Street, Philadelphia.

Salary of Medical Officers.—The salary of officers is as follows: first lieutenant, $2,000 a year and allowance for quarters, fuel and light; captain, $2,400 a year and allowance of quarters, fuel and light; major, $3,000 a year and allowance for quarters, fuel and light. The allowance for quarters is, respectively, $36, $48 and $60, and is allowed only to officers who have dependents. The allowance for fuel and light varies according to tables published by the Comptroller's department. Officers are not furnished with food, the average cost of mess varying from 75 cents to $1.25 per day.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

Arkansas: Regular Board, Little Rock, May 14-15, Sec. Dr. T. J. Stout, Brinkley; Eclectic Board, Ft. Smith, May 13-14. Sec., Dr. C. E. Laws, Ft. Smith.

Florida (H): Jacksonville, May 22. Sec., Dr. Geo. A. Davies, East Port.

Georgia: Atlanta and Augusta, May 30-June 1. Sec., Dr. C. T. Nolan, Marietta.

Hawaii: Honolulu, May 6. Sec., Dr. G. A. Batten, Box 375, Honolulu.

Illinois: Chicago, June 3-7. Mr. F. C. Dodds, Supt. of Registration, Capitol Bldg., Springfield.

Kentucky: Louisville, May 28-30. Sec., Dr. J. N. McCormack, Bowling Green.

Louisiana: New Orleans, June 6-8. Sec., Dr. E. W. Mahler, 730 Audubon Bldg., New Orleans.

Massachusetts: Boston, May 14-16. Sec., Dr. Walter P. Bowers, Room 501, No. 1 Beacon St., Boston.

Michigan: Ann Arbor, June 11-13. Sec., Dr. B. D. Harison, 504 Washington Arcade, Detroit.

Minnesota: Minneapolis, June 4-6. Sec., Dr. T. S. McDavitt, 741 Lowry Bldg., St. Paul.

Nevada: Carson City, May 6. Sec., Dr. S. L. Lee, Carson City.

New York: Albany, Buffalo and Syracuse. May 21-24. Sec., Dr. W. J. Denno, Education Bldg., Albany.

Ohio: Columbus, June 4-7. Sec., Dr. H. M. Platter, State House, Columbus.

South Carolina: Columbia, June 11. Sec., Dr. A. Earle Boozer, 1806 Hampton St., Columbia.

Tennessee: Knoxville, Memphis and Nashville, June 14-15. Sec., Dr. A. B. DeLoach, Exchange Bldg., Memphis.

Hawaii January Examination

Dr. Grover A. Batten, secretary of the Board of Medical Examiners of the Territory of Hawaii, reports the oral, practical and written examination held at Honolulu, Jan. 10-13, 1918. The examination covered 8 subjects and included 64 questions. An average of 75 per cent. was required to pass. Six candidates were examined, of whom 3 passed and 3, including 1 osteopath, failed. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
Hahnemann Med. Coll. and Hosp. of Chicago	(1917)	76
Tokyo Charity Hosp. Special Med. School	(1914)	76
University of Geneva	(1913)	91
FAILED		
University of Pennsylvania	(1896)	73
Tokyo Charity Hospital Special Med. School	(1916)	69

Indiana Reciprocity Report

Dr. W. T. Gott, secretary of the Indiana State Board of Medical Registration and Examination, reports that 4 candidates were licensed through reciprocity during 1918. The following colleges were represented:

College	Year Grad.	Reciprocity with
LICENSED THROUGH RECIPROCITY		
Bennett Medical College	(1911)	Illinois
Chicago College of Med. and Surg.	(1914)	Illinois
St. Louis University	(1916)	Missouri
Ohio Medical University	(1898)	Ohio

Iowa February Examination

Dr. Guilford Sumner, secretary of the Iowa State Board of Medical Examiners, reports the written examination held at Des Moines, Feb. 5-7, 1918. The examination covered 8 subjects and included 100 questions. An average of 75 per cent. was required to pass. Two candidates were examined, both of whom passed. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
Hahnemann Med. Coll. and Hosp. of Chicago	(1917)	85.2
St. Louis University	(1917)	85.2

Pennsylvania January Examination

Mr. Nathan C. Shaeffer, secretary of the Pennsylvania Bureau of Medical Education and Licensure, reports the oral and written examination held at Philadelphia, Jan. 8-10, 1918. The examination covered 5 subjects and included 50 questions. An average of 75 per cent. was required to pass. Of the 50 candidates examined, 42 passed and 8 failed. The following colleges were represented:

College	Year Grad.	Total No. Licensed
PASSED		
George Washington University	(1916)	1
Illinois Medical College	(1895)	1
Bellevue Hospital Medical College	(1895)	1
Cornell University	(1916)	1
Fordham University	(1916)	1
Western Reserve University	(1915)	1
Jefferson Medical College	(1915,3) (1916,13)	16
Medico-Chirurgical College of Philadelphia	(1915,1) (1916,7)	8
Temple University	(1916)	1
University of Pennsylvania	(1915,2) (1916,3)	5
Woman's Medical College of Pennsylvania	(1916)	5
Royal University of Naples	(1905)	1

Western Reserve University	(1901)	1
Medico-Chirurgical College of Philadelphia	(1916)	2
College of Phys. and Surg., Baltimore	(1914)	1

Book Notices

Essentials of Prescription Writing. By Cary Eggleston, M.D., Instructor in Pharmacology, Cornell University Medical College, New York City. Second edition. Cloth. Price, $1.25 net. Pp. 134. Philadelphia: W. B. Saunders Company, 1917.

The author has recently revised this little handbook with a view to bringing it up to date. It contains much that is valuable, and also much that is hardly necessary for medical students who are learning how to write prescriptions today. There are tendencies toward writing prescriptions in English, toward simplification of prescriptions, and toward limitation of the number of drugs to be studied and used which this little book does not take into account. Of the 127 pages twenty-two are taken up with Latin grammar.

Nine Humorous Tales. By Anton Chekhov. Translated by Isaac Goldberg and Henry T. Schnittkind. Boards. Price, 25 cents. Pp. 60. Boston: The Stratford Company, 1918.

This is the first of a series of classics to be known as the Universal Library, published by the Stratford Company. The work of Chekhov should be particularly interesting as he was a physician, and the knowledge and point of view gained from his medical practice are noticeable in practically all his stories. He has been called the Russian "de Maupassant" and also the Russian "O. Henry." Many of his stories reveal a feeling for mankind, a spicy humor, and an insight into human nature such as were possessed by those great masters.

Medicolegal

Corporate Rights of the American Medical Association

(People ex rel Maclay Hoyne, v. W. W. Grant et al.)

Mr. Justice Farmer delivered the opinion of the Supreme Court of Illinois, in affirming the judgment of the Appellate Court:

This is an appeal from a judgment of the Appellate Court for the First District affirming a judgment of the circuit court of Cook County sustaining a demurrer to and dismissing an information in the nature of quo warranto to oust the defendants to the information from the office of trustees of the American Medical Association, a corporation not for pecuniary profit, organized under the laws of Illinois in 1897. The Appellate Court granted a certificate of importance, on which the case is brought to this court by appeal.

The question raised and on which we are asked to pass is the right of a corporation not for pecuniary profit, organized under the laws of the state of Illinois, to adopt a constitution or by-laws by which the members of the association can be deprived of the right to vote for the election of trustees, and which permit or authorize the election of a board of trustees outside the boundaries of the state of Illinois.

Articles 3 and 4 of the by-laws are as follows:

"Article 3. *Membership.*—The membership of this Association shall consist of such members of the constituent associations and of such medical officers of the Army, of the Navy and of the United States Public Health and Marine-Hospital Service as shall make application in accordance with the by-laws hereinafter provided.

"Article 4. *Constituent Association.*—State and territorial nedical associations which have or which hereafter may ecome organized in accordance with the general plan of rganization of the American Medical Association and . . . leclare allegiance to the formation and the perpetuation of he House of Delegates of the American Medical Association shall be recognized as constituent association," etc.

Section I of Article 5 provides that the business body shall be known as the "House of Delegates" and consist of delegates elected by constituent associations, by the scientific sections of the American Medical Association, from the medical departments of the Army and the Navy and from the United States Public Health and Marine-Hospital Service, and that the house of delegates shall represent the delegated powers and shall be the national representative body of the constituent associations. The membership of the house of delegates was not to exceed 150.

The information was filed on the relation of Dr. G. Frank Lydston, who alleged in his petition, on which the information was filed, that he is a member in good standing of the Chicago Medical Society, which is a constituent association of the American Medical Association, and is also a member of the latter association. The information alleges that the by-laws of the American Medical Association provide for the election of delegates to the national House of Delegates, which House of Delegates shall elect three trustees each year, "at such place in such city and state as such house of delegates might assemble." The information alleges the American Medical Association had no authority, under its charter or the laws of the state, to adopt a constitution or by-laws by which the members of the association may be deprived of the right to vote for the election of trustees or which authorize the election of trustees outside of the state. It is then alleged that certain of the trustees were elected by the House of Delegates at Minneapolis, certain of them at Atlantic City, N. J., and certain of them at San Francisco, and that they were not lawfully elected and are usurpers of said office of trustees.

If the law governing the conduct of corporations organized for pecuniary profit in this state applies also to corporations organized not for pecuniary profit, it would have to be held that a meeting of the officers or directors held outside of the state and the election of trustees by delegates to such a meeting would be unlawful and the action void unless previously authorized or subsequently ratified. The first twenty-eight sections of the chapter of our statutes entitled "Corporations" relate to corporations organized for pecuniary profit. No provision of that part of the chapter relating to corporations organized for pecuniary profit contains any intimation of any right of a corporation to hold meetings beyond the limits of the state except Section 20, which permits a meeting to be held beyond the limits of the state where the meeting was authorized or the action taken at such meeting ratified by a vote of two thirds of the directors, trustees, or officers corresponding to trustees, at a regular meeting. When a meeting is held outside the state by the corporate officers without being previously authorized or subsequently ratified, as required by Section 20, the action of the officers will be void; but where the meeting outside was authorized or afterward ratified, the action of the corporation is as valid as if taken or had within the state (*Place v. People*, 192 Ill. 160). Sections 29 to 34, inclusive, of the chapter on corporations apply to corporations not organized for pecuniary profit. Section 32 provides that corporations not for pecuniary profit may elect trustees, directors or managers "in such manner, at such times and places, and for such period as may be provided by the certificate of incorporation, or in case such certificate does not contain such provisions, then as may be provided by the by-laws, which trustees, directors or managers shall have the control and management of the affairs and funds of the corporation, society or association." Here the by-laws provided the manner in which trustees should be elected, namely, by the House of Delegates selected by the constituent associations, and provided that the times and places of such election should be fixed and determined by the House of Delegates, subject, however, to change by the unanimous action of the Board of Trustees at any time prior to two months of the time selected for the session. "The annual session may be held at any place in the United States." Pursuant to its by-laws the American Medical Association, at meetings held in the states of New Jersey, Minnesota and California, elected the trustees made defendants to the information.

The statutes relating to the control and conduct of corporations organized for pecuniary profit and those relating to the control and conduct of corporations organized not for pecuniary profit are not the same (*Santa Clara Female Academy v. Sullivan*, 116 Ill. 375), and the reasons for their being different are very apparent. Corporations not for pecuniary profit have no capital stock and pay no dividends. Many of them have constituent associations (as is the case with the American Medical Association) throughout the various states of the Union and hold national meetings at stated times, composed of representatives selected by the constituent associations. The life and success of such corporations depend on their being able to hold, and in holding, meetings and transacting business at various places selected throughout the United States. The reasons and the necessity for applying a different rule with respect to the places of holding meetings by corporations organized not for pecuniary profit and corporations organized for profit were fully stated in *Derry Council v. State Council Junior Order United American Mechanics*, 197 Pa. St. 413; 80 Am. St. Rep. 838.

It seems reasonably to follow that if a corporation not organized for pecuniary profit may hold meetings at stated times outside of the state of Illinois, composed of delegates selected by the constituent associations, for the transaction of the business of the corporation, it is not unlawful to authorize and provide for the election by said House of Delegates of trustees of the corporation. The American Medical Association was organized solely for the purpose of the advancement of medical science. Its purpose was to improve methods for the treatment and prevention of diseases of the human race. Its usefulness for these purposes would be seriously interfered with, if not absolutely destroyed, if it could not provide for the election of trustees from the most efficient men in the Association throughout the United States, by delegates selected by the constituent associations from the various states in the Union. Such authority to the House of Delegates is conferred by the by-laws and is not in conflict with or prohibited by the constitution or laws of Illinois relating to corporations not for pecuniary profit (Hurd's Stat. 1917, chap. 32, sec. 32).

One question not insisted on in this court but which was urged in the Appellate Court and is extensively treated in the opinion of that court we think should be referred to here. When the relator, Dr. Lydston, presented a petition to the state's attorney of Cook County for leave to file an information in the nature of quo warranto and requested the state's attorney to file the information, the request was refused. Thereupon the relator filed a petition in the circuit court for a writ of mandamus to compel the state's attorney to sign a petition for leave to file the information. A demurrer was sustained to the petition by the circuit court and the petition dismissed. Relator appealed to the Appellate Court for the First District, which court in its final judgment reversed the decision of the circuit court and remanded the cause to that court. The Appellate Court in its opinion treats the entire merits of the controversy the same as if the information had been filed, and expresses the view that the corporation had no authority to elect trustees outside the state and that the house of delegates could not lawfully elect trustees. When the case was reinstated in the circuit court the demurrer was overruled in obedience to the mandate of the Appellate Court and a judgment entered awarding the peremptory writ of mandamus against the state's attorney. The Appellate Court, on appeal, affirmed that judgment for the reason it considered the previous decision and judgment of the Appellate Court conclusive on the Appellate Court on this second appeal. The appellant presented to this court a petition for a writ of certiorari, which was denied, and thereafter, in obedience to the writ of mandamus, the state's attorney signed the petition and filed the information, and the question presented in this case is the sufficiency of the information. The question raised in the Appellate Court but not insisted on here is that the denial of the writ of certiorari by this court amounted to an affirmance of the judgment of the Appellate Court, is res judicata and conclusive on this court.

The case before the Appellate Court on a petition for mandamus was a different case, and the parties to it were different parties, from the case and parties here before us. In the mandamus case it was sought to compel the state's attorney to sign the petition for leave to file, and to file, the information. If the petition made a prima facie showing of a proper case, it was the duty of the state's attorney to sign it, and the merits of the question would be determined on the information when filed, in which case those whose rights were attacked would have an opportunity to be heard. The real question, therefore, presented to the Appellate Court for determination was whether the petition for leave to file the information made such prima facie showing that the state's attorney should have signed it and presented it. The denial of the writ of certiorari, therefore, meant nothing more than that we approved the conclusion of the Appellate Court that the state's attorney should have signed and presented the petition. It did not mean that we approved the reasons set out in the opinion of that court and its determination of the merits of the case, and of the rights of the parties to be affected by the information when filed (*Soden* v. *Clancy*, 269 Ill. 98). Until the information was filed, the parties defendant to it had no right to be heard or to present their defense. They were not parties to the mandamus proceeding.

Transformation of Homosexuality by Implanting Testicles. —The *Nederlandsch Tijdschrift* mentions briefly an article by E. Steinach and R. Lichtenstern in the *Münchener medizinische Wochenschrift* describing experimental research on the influencing of sexual characters by gland implantation, and a clinical case. This was in a homosexual man of 30 who had to be castrated on account of a tuberculous lesion. They implanted in the external oblique muscle, on both sides, half of an undescended testicle taken from a sexually normal man. It is said that the man felt heterosexual directly after the operation and the feminine characteristics he had previously presented became transformed in the male direction, and he married a year later.

AMERICAN ASSOCIATION OF IMMUNOLOGISTS

Meeting held at Philadelphia, March 29 and 30, 1918

The Rôle of Immunity in the Conduct of the Present War

Dr. John A. Kolmer, Philadelphia: Many practical problems lie before the immunologist. One is the discovery of a practical test, analogous to the Schick test, to ascertain the presence of a natural immunity to pneumonia and meningococcus meningitis, if such immunity exists. This may also obtain in the case of tetanus. Measles, anterior poliomyelitis, syphilis and gonorrhea are diseases that must be combated by some means of active immunization, not forgetting that problem of problems, the question of immunization against tuberculosis.

Active Immunity in Experimental Poliomyelitis

Dr. H. L. Abramson, New York: Rabbits were found to be unsatisfactory experimental material, and young *Macacus rhesus* monkeys were chosen for the work. An attenuation of the poliomyelitis virus was aimed at, bearing in mind the analogy to the rabies virus. The virus was exposed (1) to heat and (2) to chemical action. In the latter modification, 0.5 per cent. formaldehyd was used. The monkeys sickened and died of what was termed the marantic type of monkey paralysis. Modification by heat was then used, two methods of vaccine injection being tried. The first one consists of four successive daily injections of 5 c.c. of 10 per cent. emulsion in saline of brains and cords of recently infected monkeys. On the fifth day the animals received 5 c.c. of virus emulsion, unmodified by heat. The second type of vaccine was a 5 c.c. injection, on ten successive days, of emulsion in saline of brains and cords of infected monkeys, heated to 55 C. for a half hour. This was really a killed virus. It was then sought to determine the amount of immunity by the animals, and also the neutralizing properties of their blood serum. Eleven monkeys were subjected to the five day injection series, without ill effect. This method, being short, makes it particularly applicable during an epidemic. It seems to confer a strong degree of immunity.

Persons that have recovered from poliomyelitis contain in their blood neutralizing substances, and the same is true of monkeys. These substances can be artificially produced, and in sufficient quantity to overcome infection of human poliomyelitis, which is far less virulent than the type of disease produced in monkeys, experimentally.

DISCUSSION

Dr. A. F. Coca, New York: It is important to emphasize the concluding remarks of Dr. Abramson. The conditions under which he was working to produce immunity were highly artificial, and this defense was more than was necessary to constitute an absolute resistance to the natural infection as occurring in human beings. The natural resistance might need very much less than the artificial one. In the artificial experiments, resistance was circumvented.

Dr. W. H. Park, New York: I can say one word in line with Dr. Coca's remarks. In test animals, one may react, and one may not react. The rabbit gives very feeble protective serum: the monkey gives better serum, but the horse gives as good or even better serum than the monkey. Perhaps Dr. Abramson would say a word on that question. In my own experiments I first used virus from the brain, digested by trypsin, and then straight virus. Different animals showed a different period of development of antibodies and also a different degree.

Dr. John A. Kolmer, Philadelphia: Has the serum been used in the treatment of human infections?

Dr. H. L. Abramson: In regard to rabbit poliomyelitis, I spent about six months inoculating animals to get signs of paralysis. I did not test for immune bodies. I then subjected monkeys to injections of virus from rabbits. The virus of the 1916 epidemic was tested. The incubation period was variable. The control came down in six days. The animal injected with rabbit cord came down in fourteen days.

The Types of Meningococci Concerned in Epidemic Infections

Drs. A. Parker Hitchens, Glenolden, Pa., and G. H. Robinson, Uniontown, Pa.: The troops in this country are now undergoing the same conditions as the British troops at the beginning of the war. The work of Gordon on the meningococci is of value. He classified the different strains, as had been done with the pneumococci, into four different types. In the present experiments, 100 cultures, received from the first of the year, have been classified into types according to the Gordon method. The strains had come from several concentration camps in this country. The cultures are gram-negative cocci and correspond more or less to Gordon's types, namely, I, parameningococcus; II, normal meningococcus; III and IV, types comparatively rarely found in this country. Each camp has a predominating type, but whether this is a true epidemic is not determined. It is hoped that specific serums may be evolved to counteract the types, as Gordon had excellent results with his specific strains. He found that if specific serum were given before the third day of the disease the mortality was only 9 per cent.; if on the seventh day, the mortality was 50 per cent.

The Influence of Active Normal Serum on Meningococci

Drs. John A. Kolmer, I. Toyama and T. Matsunami, Philadelphia: Fresh serum, both normal and immune, has greater antibacterial properties than old serum, the latter having sustained a loss of antibodies as well as complement and opsonins. Antimeningitis serum is rich in opsonins and has high phagocytic properties. Recovery from meningitis is in great measure due to this phagocytosis. A clinical test, the addition of 1 c.c. of fresh sterile human or guinea-pig serum to each 9 c.c. of antimeningitis serum, before intraspinal injection, would be of value for the purposes of increasing phagocytosis of the micro-organisms, especially in cases of severe and serum-resistant meningococcus meningitis.

The Influence of Active Normal Serum (Complement) on Meningococci

Drs. T. Matsunami and J. A. Kolmer, Philadelphia: We found that the bactericidal activity in vitro of different antimeningitis serums is quite low. Fresh or active antimeningitis serums are somewhat more bactericidal than the same serums after inactivation by heating at 60 C. for thirty minutes. Active normal human and guinea-pig serums are slightly bactericidal for meningococci. Horse antimeningitis serum and normal human and guinea-pig serum are also found to have a bactericidal activity, independent of complemental bacteriolysis. It is further found that the use of whole blood was of more effect than the use of serum alone. The final conclusions from these experiments is that the addition of active normal human or guinea-pig serum (complement) to antimeningitis serum does not greatly add to bactericidal activity, as bacteriolysis is unimportant in antimeningitis serum; but it is also found that opsonic activity (an important curative factor) is greatly increased by such addition. Moreover, it is considered worth while, in view of these findings, to use clinically an antimeningitis serum to which has been added active human or guinea-pig serum, prior to intraspinal injections, especially in severe and serum-resistant cases. In this respect human serum is superior to guinea-pig serum, when proper aseptic precautions are maintained.

DISCUSSION

Dr. William H. Park, New York: I should like to ask a question as to the use of "specific therapy" in the treatment of cerebrospinal meningitis. Could not one get a serum for one type which would be stronger than the polyvalent serum? If one or two types could be injected into the horse at once and an antiserum produced, the advantage would surely be greater than if one used two different horses for those types. Has a true polyvalent serum been produced?

Dr. A. P. Hitchens, Glenolden, Pa.: Dr. Park's point is well taken. There may, however, be greater possibility of reducing the death rate through the use of specific serums. It was possible that there might be immunologic variations of meningococci within the serologic types. It was well known that, with the best balanced serums obtainable, one finds cases of meningitis to resist the action of the polyvalent serum. Meningococci can not be accurately and sharply grouped within certain types, but follow the order of a chromatic scale. There are an almost innumerable number of slight variations.

Dr. Charles Krumwiede, New York: I am interested in the precipitin test diagnosis of type, but I am far from accepting its specificity. There are reactions alike for Types I and III, and Strain II will pick up Strain IV. Before progress can be made, an easier way of differentiation must be found; but I feel a little hopeless about discovering it.

A Rapid, Simple Method for Extraction of Precipitin Antigen from Bacteria

Dr. Charles Krumwiede, New York: This is not original, but it demonstrates the extraordinary resistance of bacterial precipitin antigen to both heat and chemicals. A very heavy suspension of bacteria is necessary for the technic. Antiformin is added and the mixture is kept boiling till the bacteria are dissolved. Phenolphthalein is next added, then hydrochloric acid, and finally alcohol. The solution is then dissolved to twenty times its volume with saline, to get rid of bacterial rests. The clear solution results in an extract to be diluted from fifty to 200 times. The essential point is to start with a very heavy bacterial suspension. Acid-fast bacteria can not be used for this method, as they are not dissolved by the solution.

DISCUSSION

Dr. George Smith, Glenolden, Pa.: Is this as valuable for the production of other immune bodies, when employed as antigen?

Dr. Charles Krumwiede, New York: I have tried to produce immune serum to the antigen. It does not produce any antibodies.

Observations on the Intraspinal Auto-Arsphenamized Serum Therapy of Cerebrospinal Syphilis

Dr. Benjamin A. Thomas, Philadelphia: Cases of tabes are often found that do not respond to treatment. The spinal fluid sometimes gives a positive Wassermann reaction, when the blood is negative. In four years' experience I have used auto-arsphenamized serum. Intraspinal injection is given after intravenous injection, under careful sterile technic. An amount of spinal fluid is removed equal to the amount injected. The foot of the bed is raised after treatment. The treatment is continued until the spinal fluid is permanently negative. If improvement is found to follow intensive intravenous treatment, the intraspinal injection is not used. Degeneration of the cord cannot be affected by intraspinal methods of treatment. Vascular cases are found to respond better to intravenous treatment alone.

DISCUSSION

Dr. H. L. Abramson, New York: Was whole serum used, or was it diluted with salt solution?

Dr. J. A. Kolmer, Philadelphia: At the Polyclinic in Philadelphia we have a large number of cases of syphilis, under Dr. Schamberg's care. A number of intraspinal injections are given. We believe that something can be gained by arsphenamizing the serum in vitro after Ogilvie's method.

Dr. B. A. Thomas, Philadelphia: We diluted neither serum nor spinal fluid. I think that that is an open question. I do not put the patient under the ordeal of intraspinal injection, if it can be avoided.

(To be continued)

TENNESSEE STATE MEDICAL ASSOCIATION

Eighty-Fifth Annual Meeting, Held at Memphis, April 9-11, 1918

The Surgical Treatment of Chronic Gastric and Duodenal Ulcers

Dr. R. L. Sanders, Memphis: In the surgical treatment of duodenal ulcer, posterior all catgut gastro-enterostomy is the method of choice. In selected cases, pyloroplasty, after the method of Finney, is very satisfactory. When the ulcer is small and no obstruction present, it may be excised and the opening closed after the method of Heineke-Mikulicz. If there is a recurrence of symptoms, it is probably due to faulty technic.

The mortality is much higher in excision with the knife than that by the actual cautery. Balfour has shown that cautery excision of the ulcer is quite safe and that the resulting scar produces a limited amount of deformity. The heat destroys the ulcer and also the cancer liability. The opening thus made should be closed with chromic catgut and reenforced by a layer of omentum to prevent leakage. Gastro-enterostomy should always accompany this procedure.

DISCUSSION

Dr. J. Hugh Carter, Memphis: While it is difficult to differentiate between gastric and duodenal ulcers and gallbladder diseases, as they are closely associated, yet it can be done by going over the history of the patient carefully and using the roentgen ray as an aid to diagnosis.

Dr. G. C. Savage, Nashville: I believe every operating room, where the stomach or duodenum is to be operated on for ulcer that may be cancerous, should be equipped with the machinery for producing the high frequency current of electricity, and that the spark desiccation treatment should be used, and not the galvanocautery or thermocautery.

Dr. E. J. Johnson, Memphis: In any attempt to remove a duodenal ulcer we must consider the necrotic condition of the tissue due to extension of the ulcer beyond the reach of the finger, and we may have an additional sloughing.

Some Unsettled Points in the Etiology of Appendicitis

Drs. E. H. Baird and J. P. Baird, Dyersburg: Concurrent or recent attacks of tonsillitis and other infections of the upper air passages given in the histories of cases of appendicitis, especially in children, cause one to associate these cases together. In a certain number of these cases, pus has been taken from the gums, from the gallbladder or appendix, and cultures, and the predominating infection found in one closely corresponded to the other.

DISCUSSION

Dr. Jere L. Crook, Jackson: We are still losing 10 per cent. of all cases from appendicitis regardless of the time when operation is performed. This mortality in practically every instance is due to delay in removing the appendix. I have found a number of cases of appendicitis due to diseased teeth, both in children and in adults.

Dr. John L. Jelks, Memphis: I have known of a number of cases of pellagra in this section in which operation has been performed under the mistaken diagnosis of appendicitis. I would sound a note of warning not to operate in cases of appendicitis without a blood count.

Dr. E. J. Johnson, Memphis: With reference to relying exclusively on a blood count, I agree with Dr. Jelks that if it is always convenient, a blood count should be made. On the other hand, I have seen a good many cases in which blood counts made by competent pathologists were negative, yet the clinical symptoms were positively convincing, and after the abdomen was opened, a badly diseased appendix was found and removed. If one relies too much on a blood count, some patients may be lost from appendicitis that might be saved by operation.

Dr. William Krauss, Memphis: A surgeon is never justified in going into the abdomen for an acute condition without a blood count, and this blood count should include both total and differential. A surgeon ought to have sense enough to estimate the value of the various points in his evidence before he operates. If his total and differential blood counts are negative, and he has other reasons to suppose that an operation is necessary, it is a question for his surgical judgment of what he is going to do next.

Dr. Robert Caldwell, Nashville: I grant that occasionally we see an acute appendix case in which there is not a leukocytosis. In my experience I recall only one such case. In all the others there has been a leukocytosis. I think we ought to have a blood count in all these cases if we are going to do scientific surgery.

Surgery of the Thyroid

Dr. J. B. Haskins, Chattanooga: A simple adolescent goiter should be given an opportunity to subside under proper management, and if it does not disappear after puberty is well established, it should be removed. In cases in which the enlargement begins to increase, operative treatment is especially advisable, as the gland will surely make pressure and may possibly change its form and become toxic.

DISCUSSION

Dr. W. D. Haggard, Nashville: The adolescent types of goiter ought not to be operated on, as these patients get well without treatment and in spite of treatment; whereas the smooth adenomatous type of goiter should be removed because its growth is rapid. It is a deformity. It tends to undergo degeneration, and its enucleation is very simple. The large colloid tumor can be benefited in the early stages by iodin, and sometimes cured; but it becomes a nuisance on account of the deformity resulting, and is not an unmixed blessing because it occasionally undergoes not only malignant but sometimes toxic degeneration; hence this type of goiter should be removed.

Complete Intestinal Obstruction from Carcinoma of the Sigmoid and Rectum

Drs. W. D. Haggard and W. O. Floyd, Nashville: Our experience in five cases justifies the following conclusions: 1. Intestinal obstruction from carcinoma of the sigmoid and rectum is preceded by a very definite set of prodromal symptoms. 2. These symptoms consist of attacks of colic, nausea and vomiting, without elevation of temperature, with a left-sided tenderness or tumefaction, with or without much pain, and with constipation, obstipation, loss of weight, and blood in the stools, over a period of a few to many months. 3. With these symptoms, especially in a patient within the cancer bearing age, a roentgen examination of the colon should be made, and if necessary an exploration to determine the diagnosis before complete obstruction has occurred. 4. With carcinoma undisturbed, it being one of the most deadly conditions known to the physician, why should we, with the foregoing symptoms, allow our patients to go undiagnosed until obstruction actually occurs, which, without operation, is one of the most rapidly fatal lesions encountered within the abdominal cavity, and which with operation carries with it one of the highest mortality rates known to surgery?

DISCUSSION

Dr. John L. Jelks, Memphis: Cancer of the sigmoid is not disseminated as quickly as cancer elsewhere. Cancer of the sigmoid may remain latent for a long time, and cancer of almost any part of the colon is later in its metastasis than are cancers in some other localities. A diagnosis of cancer of the intestine, especially of the rectum and sigmoid, should never be delayed until bloody stools appear. Certainly, the diagnosis of, at least, a suspicious condition should be made by proctoscopy and sigmoidoscopy long before the latent and late symptoms appear.

Acute Osteomyelitis

Dr. E. M. Sanders, Nashville: Acute osteomyelitis is in all probability primarily a metastatic condition, and the focus exists, or has existed, in the patient, being regarded innocent perhaps at the time. Typhoid fever sometimes gives rise to symptoms very similar to those of osteomyelitis, but the Widal and leukocyte count will usually differentiate the conditions. In the fulminating type, in which convulsions and delirium are the first symptoms, the local condition may be overlooked until the postmortem clears up the case. The roentgen ray, when available, should always be tried; but a negative picture means nothing.

The Proper Interpretation of Bladder Symptoms

Dr. George R. Livermore, Memphis: Bladder symptoms may be due to disease of any part of the genito-urinary tract. A cystitis that does not respond to bladder irrigations in a short time is, in the majority of cases, due to infection higher up; but it is a fact that a cystitis may persist, even after the infection higher up has been eradicated. A pyelitis, due to infection following traumatism induced by a calculus, may clear up under pelvic lavage, diuretics, and rest in bed, with consequent relief of bladder symptoms, only to have both return if the stone is not removed. Therefore, it is important to find the cause, for it would be unfair to irrigate the pelves of the kidneys for a pyelitis that was constantly being reinfected from a pus pocket in the tonsils.

Contracture of the neck of the bladder, prostatic bar and hypertrophy of the prostate produce similar symptoms, and as the treatment is so different one should be sure that one's diagnosis is correct before subjecting patients to treatment. Every person presenting bladder symptoms should be subjected to a complete physical, chemical, microscopic, cystoscopic and roentgen-ray examination before treatment is begun, for only by such painstaking study can one accurately locate and scientifically treat diseases of the genito-urinary system.

Surgical Treatment of Varicose Veins

Dr. William S. Anderson, Memphis: The following operation has proved satisfactory: About an inch below Poupart's ligament a transverse incision is made in the groin 2 or 3 inches long, and through this the saphenous vein is exposed at the opening and ligated; the vein is now dissected by the Mayo stripper or any other satisfactory means down to the region just below the knee. At this point open dissection should be used, for here the larger branches of the great vein begin to enter, and it is always advisable to dissect out all the veins of the calf down to where they are very small. This is easily done by a long cut from the knee to the ankle down to the deep fascia, turning back the flap of skin and fat and dissecting out the veins. The cure of the ulcer depends largely on the complete removal of the vein; but if the ulcer is associated with a thick base of scar tissue, it is best to remove it down to or better through the deep fascia with the mass of poorly nourished scar tissue beneath and around them. This procedure may lay bare quite an exposed area, and it is best to cover this at once with Thiersch skin grafts. The third requisite is secured by the proper nourishment of the skin and the proper healing of the wound by perfect hemostasis, proper asepsis, and delicate handling of the tissues.

The whole leg is kept well bandaged, immobilized and elevated for one week. After this the calf should be kept well bandaged for a week longer. After slight exercise the patient is allowed to get up. The leg to the knee should be kept well supported by a well applied bandage for several weeks longer, and then the bandage discarded.

Current Medical Literature

AMERICAN

Titles marked with an asterisk (*) are abstracted below.

American Journal of Orthopedic Surgery, Boston

April, 1918, 16, No. 4

1 *New Procedure for Compensatory Shortening of Unaffected Femur in Cases of Considerable Asymmetry of Lower Limbs (Fractures of Femur, Coxalgia, etc.). J. Calvé and M. Galland, France. —p. 211.
2 Some Conditions of Artificial Stumps. E. M. Little, England. —p. 236.
3 Results of New Operation for Obstetric Paralysis. J. W. Sever, Boston.—p. 248.
4 *Treatment of Lesion of Musculospiral Nerve in Military Surgery. N. Dunn.—p. 258.

1. Compensatory Shortening of Femur.—Three procedures are proposed by Calvé and Galland: First, "autopegging;" second, a "setting procedure;" third, "the procedure of direct holding" (dovetailing) which the authors have practiced twice on the living subject, is difficult of execution if it is to be carried out with true mathematical precision. It is better not to employ this method. Autopegging: The upper fragment is cut obliquely, with the obliquity from above downward, from within outward, and from the back forward, following a predetermined plan. Due to the mechanical procedure, the lower fragment presents an exactly identical obliquity. At the lower part of this section, that is to say, the part lowest down and to the outside, a quadrangular tenon is cut out with a rotary electric saw. The tenon is inserted and sutured into the medullary canal of the upper fragment. Experience has shown that angular displacement of the lower fragment (anterior, posterior, or lateral) is impossible. Setting by tenon and mortise. The lower fragment is cut as in the preceding method, but the extremity of the tenon is bevelled on its upper face. The tenon, as in the previous method, presents lateral parallel cut surfaces. The upper fragment has the same oblique section as before, but a mortise is cut which allows the exact fitting in of the tenon. When the osseous extremities are fitted in, the oblique section prevents the forward and outward displacement of the lower fragment. The tenon, held by strong catgut or reindeer tenon, cannot fall into the medullary cavity, which prevents the backward and inward displacement of the lower fragment. The tenon set in the mortise prevents lateral displacement. Finally, on account of the bevelling of the tenon on the upper surface, it cannot slip round and get out of the mortise. Direct holding (dovetailing). Two lower tenons are set in two upper mortises; two upper tenons are set in two lower mortises. Each of these tenons is the crown of an arch, and one ought to prevent backward displacement, while the others oppose displacement forward and to the side.

4. Treatment of Lesion of Musculospiral Nerve.—Dunn has had under treatment at the Military Orthopedic Hospital, Shepherds Bush, twenty-six cases of partial or complete lesion of the musculospiral nerve or its branches. Preoperative treatment of the lesion included: (*a*) splintage; (*b*) electrical treatment and massage. The method of suture which Dunn has adopted has been transfixion of the nerve by a single suture to maintain apposition until the sheath has been united by either continuous or interrupted sutures, when the tension suture can usually be removed. The nerve can then be wrapped in cargile membrane, egg membrane, or fascia, etc. Dunn has seen recovery take place where no ensheathing membrane has been used, and it has been his practice for the last ten months to dispense with wrapping. The points he attaches most importance to are careful handling of the nerve—uniting the nerve without torsion, so that bundles, originally in continuity, are again in apposition; taking care that the fine suture bites the sheath only, and unites its edges accurately, and where much scar tissue is present, embedding the nerve in healthy muscle substance. If the lesion is the result of a clean bullet wound, Dunn says, operation may be safely performed as soon as the superficial wounds are healed.

In cases in which the wound has been septic, it is his practice to allow at least two months to elapse after the last sinus has healed before proceeding to suture of the nerve, and in cases in which there has been involvement of bone with the scar adherent, it is advisable to excise the scar, suturing the nerve a fortnight later if primary healing has taken place. Where the case is complicated with limitation of the flexion of the elbow, it is important to overcome this before suture, as the position of acute flexion in the pronated position, will, with stretching, allow apposition of the ends in cases in which there is destruction of 2 to 3 inches of nerve substance. This position should be maintained continuously for one month after operation. If the lesion is complicated by an ununited fracture of the humerus, one should, before proceeding to bone grafting, explore the nerve and see that suture without tension is possible, as the question of further shortening of the humerus might arise. Dunn has performed nerve grafting on two occasions only, and in neither has this proved satisfactory.

7. **Behavior of Isolated Intestinal Segments.**—Five segments excised from different parts of the rabbit's intestine were studied by Alvarez under identical conditions in warm aerated Locke's solution. He found that the segments of duodenum and jejunum have greater tone and contract more after cutting than do the ileal segments. The colon also has a high tone. The duodenal segment is generally the first to begin beating well. The tendency to rhythmic activity is graded from duodenum to ileum. The first few centimeters of duodenum, corresponding to the duodenal cap in man, does not beat well. The colon is very slow in starting up and it differs greatly from the small intestine in its behavior. The duodenum suffers more from trauma and from adverse conditions than do the other segments. Segments from sickly animals beat poorly and become fatigued early. These changes are often more marked in some segments than in others so that the gradation of rhythm is changed. The gradation of rate of contraction from duodenum to ileum is remarkably constant in normal animals. In one case the gradation was upset by the presence of an inflamed area in the ileum. The bowel in that region contracted 21.5 to 25 times per minute, or twice as fast as normal. After twenty-four hours, the segments beat at a faster rate and maintain the gradient. They continue to react normally to epinephrin and atropin.

11. **Mechanism of Action of Anesthetics.**—The authors' investigation showed that narcotics of widely different constitution, such as chloroform, ether, chloral hydrate, nitrous oxid and magnesium sulphate, decrease the catalase of the blood, parallel with the increase in the depth of narcosis. A very powerful anesthetic, such as chloroform, decreases the catalase more quickly and extensively than does a less powerful anesthetic, such as ether. Slowly acting anesthetics, such as chloral hydrate and magnesium sulphate, decrease, accordingly, the catalase of the blood more slowly than a quickly acting anesthetic such as nitrous oxid. As a result of the experiments reported in this paper, and of work done previously on the anesthetics in this laboratory, the theory is advanced that narcosis is due to the direct destruction of catalase by the narcotic, with resulting decrease in oxidation, while recovery from anesthesia is brought about by an increase in catalase due to the increased output from the liver, with resulting increase in oxidation.

12. **Growth Capacity and Weight at Birth.**—Hammett says that the growth capacity of human infants during the first two weeks after birth is in a large degree dependent on the weight at birth. It is roughly inversely proportional to the initial weight. The ability to recover and pass the initial weight after the postnatal decline obviously varies in the same way, so that at the completion of the period studied some 82 per cent. of those infants weighing between 5 and 6 pounds at birth have recovered or passed their initial weight, as compared with 20 per cent. of those weighing from 10 to 11 pounds. The intermediate groups vary inversely as to their weight at birth.

16. **Effect of Pituitary Extract on Urine Output.**—An investigation was made by Rees to find out, first, whether the subcutaneous injection of pituitary extract will cause any quantitative variation in the daily output of urine; second, whether such injection will in any way affect the quantity of urine excreted, and, if so, to find out if possible the factors involved. He found that subcutaneous injections of pituitary extract do not alter quantitatively the daily output of urine in cats and rabbits, nor do they cause any marked variation in the specific gravity of the urine. The subcutaneous injection of pituitary extracts causes a delay of seven to eight hours before the beginning of the diuresis which follows the ingestion of large amounts of water. This delay, however, does not cause any variation in the total amount of urine excreted in twenty-four hours. The delay in diuresis which is produced by subcutaneous injection of pituitary extract is due in part at least to a delayed absorption from the alimentary canal. The subcutaneous injection of pituitary extract has no influence on the diuresis induced by a continuous intravenous injection of isotonic salt solution.

17. **Stages of Circulatory Failure in Abdominal Shock.**—The fundamental aim of this research was to analyze the consecutive changes evident in optical records of the right auricular, right ventricular and central arterial pressures. The course of the circulatory failure in abdominal shock is divided by Wiggers into three stages: 1. The initial stage, lasting about thirty minutes after intestinal exposure, during which effective venous pressure and cardiac discharge are apparently not appreciably reduced but the arterial pressure,

as recorded precisely shows distinct alterations not adequately indicated by mean pressure manometers. 2. The progressive stage, lasting two to four hours, during which effective venous pressure falls progressively, cardiac efficiency is impaired and the arterial pressure falls toward a low level. The heart usually accelerates. 3. Complete circulatory failure, marked by a prolonged period during which effective venous pressure has reached its lowest level and the arterial pressure slowly falls further until death supervenes. During this stage cardiac slowing usually takes place. A careful study of the optical tracings of arterial, intraventricular and auricular pressures, accompanied by constant readings of the mean arterial and effective venous pressures during these stages, corroborates the conclusion—in the ascendency at the present time—that the decreased venous pressure and consequent reduction in minute output is the predominate factor in the pronounced fall of arterial pressure during the progressive stage of shock. The dynamics of the circulation indicate clearly, however, that a reduction in peripheral arterial resistance initiates the fall of arterial pressure and the diminished filling of the arterial trunks before the effective venous pressure and cardiac discharge are reduced. The rôle that a diminished arterial resistance plays in the circulatory failure is therefore directly established for the first time.

18. **Mode of Action of Food in Increasing Oxidation.**—The authors conclude from their observations that alcohol increases the catalase of the blood by stimulating the pancreas, the spleen, the gastric and intestinal glands and particularly the liver to an increased output of this enzyme. It is permissible, perhaps, to assume that food like alcohol stimulates the production of catalase in the organs mentioned and in this way causes an increase in oxidations.

21. **Effect of Epinephrin on Urine Flow in Dogs.**—Gunning found that epinephrin in all effective dosages administered intravenously inhibits the urine flow in both anesthetized and unanesthetized dogs. The threshold of the reaction is slightly lower in unanesthetized than in anesthetized animals. Small injections and infusions merely inhibit the flow of urine while larger doses produce a complete cessation of flow. The inhibition usually persists until shortly after the blood pressure reaction is complete. Diuresis succeeding the inhibition was not observed. The rapid return of the flow to normal after prolonged infusions suggests that the drug exercises its inhibition on the kidney function in a way other than by the ischemia produced. During the administration of ether the urine flow is completely checked and recovery under the anesthetic takes place slowly.

24. **Auto-Agglutinin Occurring in Human Serum.**—Autoagglutination, or agglutination of red blood cells by serum from the same individual, was observed by Clough and Richter in the blood of a patient admitted to the hospital on account of a bronchopneumonia associated with chronic mitral endocarditis. Agglutination occurred only at low temperatures (below 22 C.), and broke up if heated to body temperature. Agglutination could be reproduced by again chilling the same preparation. This serum caused similar agglutination of red blood cells from other individuals of the same blood group (Group 3), and also of Group 4. (It contained ordinary iso-agglutinins active at body temperature for cells of members of Groups 1 and 2). The cells of the patient washed free from serum showed no tendency to agglutination, and behaved exactly as did cells from other individuals, Group 3. Hence the phenomenon depended solely on a peculiarity of the serum, and not of the cells. The active substance in the serum had many of the properties of an ordinary agglutinin. It was active in fairly high dilution (up to 1 : 500). It resisted heating to 60 C. for half an hour, but was destroyed at 65 C. It remained active after preservation in the icebox for several months. It was not dialyzable. It was not removed by extraction with chloroform. It was precipitated with the euglobulin by 36 volumes per cent. of saturated ammonium sulphate solution. It was absorbed from the serum during the process of agglutination (at low temperatures). It was entirely distinct from the ordinary iso-agglutinins in the serum, since either one could be removed from the serum, leaving the other intact.

The auto-agglutinin differed from ordinary agglutinins in the following ways: 1. It was active only at low temperature, the agglutination breaking up on warming. 2. It was absorbed from the serum only at low temperature, and was liberated from the cells on warming. 3. It was active on red blood cells from all of the different species of animals with which it was tested (man, rabbit, guinea-pig, hen, sheep, cat and pig). That the same substance was concerned in the agglutination of human cells and of cells from these different animals, and that it was distinct from the ordinary hetero-agglutinins, which were also present in the serum, was shown by absorption tests. No autohemolysin was present in the serum. A similar study of rouleaux formation was made in order to differentiate it more clearly from auto-agglutination. The substance causing rouleaux formation resembled the auto-agglutinin in that it, also, was active on cells from other individuals. Both substances were precipitated from the serum with the euglobulin, and neither was dialyzable. Unlike the auto-agglutinin, the rouleaux-forming substance was active only in concentrated serum. Its activity rapidly disappeared on standing, and fresh cells were necessary for the formation of rouleaux. Rouleaux formation occurred equally well at high or low temperature. Heating the serum to 65 C. increased its rouleaux-forming power. This substance was not absorbed from the serum by the cells in the process of rouleaux formation. The presence of the auto-agglutinin was probably not related in any way to the disease from which the patient was suffering. It persisted with slight variation in strength for a period of two months' observation, and was found to be present in the serum of a daughter of the patient. Hence it was probably not pathologic phenomenon, but an individual, hereditary peculiarity.

25. **Simple Method for Determination of Venous Pressure.**—An instrument for the measurement of pressure within peripheral veins has been constructed by Brown from an ordinary mercurial manometer. The apparatus consists of a single limb manometer in which water, carbon tetrachlorid or bromoform is substituted for mercury. To the manometer is connected a small, saddle shaped cup, 2 cm. in diameter, covered with the thinnest rubber tissue obtainable. This membrane must be loosely applied and should permit free oscillation without tension. A rubber bulb with thumb screw compressor regulates the pressure within the manometer. The use of carbon tetrachlorid or bromoform instead of water is advocated because of higher specific gravity and lower viscosity. The former is preferred for routine observations. The readings are reduced to water pressure. The principle employed is that described by von Basch in 1876 for the determination of arterial pressure.

37. **Device for Holding Fractures of Long Bones.**—Believing that the principle of the internal splint is sound, but that its application has been faulty, Simpson has constructed a device consisting of two parts—a screw and a cannula, and is called a bushing screw, as the device is both a screw and a bushing. The length of the screw corresponds accurately with the depth of the bore in the bone (the diameter of the bone) and is threaded only for a short distance at the head end. In oblique fractures no plate is needed; all that is necessary is to expose the fracture by incision, reduce it and with the bone held firmly drill two holes, properly located, pass the screws through and tighten them. In transverse fractures a plate is needed. The advantages of this device are said to be that when applied, it has the effect of a screw with a head on both ends. It gives a firm grip on the plate, if one is used, and on the compact tissue on the opposite side of the bone.

55 Two Cases of Gonorrheal Keratosis. W. H. Brown and A. M. Davidson, London, England.—p. 225.

53. **Case of Scleroderma Diffusa.**—The case reported by Goodman is an unusual example of acute diffuse scleroderma, in a child, 9 years of age. The disease followed a tonsillitis. It appeared first on the back of the neck, and spread so that no part of her body was left free. The heart rate was accelerated, but there was no evidence of cardiac disease. The mentality of the child was not affected. Malfunction of none of the glands of internal secretion could be determined. The child, after five months, had recovered. There remained some hardness of the scalp and of the skin of the thighs. No atrophy was present. Thyroid extract had been given for several months, but discontinued because of its effect on the heart rate and the presence of a tremor. Oil rubs had been given actively. Histologic study was not possible, as a biopsy was refused.

58. **Leukemic Infiltration in Spinal Cord.**—The case reported by Bassoe is an example of paraplegia caused by purely mechanical compression of the cord by a leukemic tumor growing into the spinal canal. There is no evidence of leukemic infiltration or old toxic degeneration of the cord. The onset of severe pain followed by paralysis evidently occurred at the time when the canal had become too small for the growing leukemic mass Bassoe says. If at that time laminectomy had been performed and the dura merely slit posteriorly, serious injury to the cord might have been avoided. However, at the time it was impossible to ascertain that no cord infiltration or hemorrhage existed and that the symptoms were of purely mechanical origin. The existence of leukemia in any form makes the patient a poor subject for a major operation, but under similar conditions, with sudden onset of signs of cord compression in a leukemic patient previously free from cord symptoms, Bassoe hereafter will at least seriously consider the advisability of an operation.

76. **Sequel to Measles.**—In each instance seen by Vroom the early course of the attack of measles was uneventful, pursuing the classical course with headache, rise of temperature, cough, conjunctivitis, and measles eruption over the face and body. On the sixth or seventh day from the advent of the eruption, the patient suddenly developed a sore throat in the nature of an acute pharyngitis: red, engorged and painful, a marked aphonia, a sharp rise in temperature to 103 to 104 F., and pronounced epistaxis. Large moist bronchial râles in both lungs became evident early, accompanied with very acute pleuritic pain, usually in one side. In those cases that event-

ually pursued a severe or fatal course, fine crepitant râles became evident on about the second day, followed with an effusion into one or both pleural cavities; at first serous in character, but with a tendency rapidly to become purulent. Percussion gave no evidence of pulmonary consolidation, nor did postmortem findings reveal such. Expectoration from the first profuse yellow, glairy, with not the tenacity of that of lobar pneumonia; it was very markedly streaked with bright blood, and was not blood stained. In those severely ill, the expectoration became scanty and rather frothy in character, on the third or fourth day, and the fine crepitant râles remained pronounced. Cyanosis was a symptom appearing on the second day after the sudden rise in temperature. The patients complained of a tightness across the chest and would allow themselves to be moved in bed only under protest. The lips became indented and covered with brown crusts. The pulse respiration ratio was 1 to 3. The blood pressure registered 90 to 95 systolic, and 60 to 75 diastolic. Pleural effusions occurred early, often on the second day. The cyanosis, often an early symptom, had every evidence of being a resulting carbon dioxid poisoning from the failure of the highly congested and inflamed pulmonary alveoli to functionate in exchanging carbon dioxid for oxygen. The patients who did not survive, generally died within the first week; those that lived, have passed through a slow and tedious convalescence, the fine crackling râles slowly disappearing and the cyanotic condition passing away. The aphonia has been quite persistent. The pathologic and bacterial findings have not been worked out sufficiently for presentation. The mortality occurring from these so-called bronchopneumonia cases was 27 per cent.

1. Primary Suture of Wounds.—Bowlby presents a summary of the results obtained in the treatment of wounds by various methods and emphasizes one method in particular, that of primary suture of wounds. He says that while success depends on many conditions which are beyond the control of the surgeon, it depends very largely on the surgeon himself. Primary suture of wounds is more likely to end in disaster than in benefit unless the operation is most carefully performed, and this implies, in the first place, the most minute aseptic precautions, such as are commonly practiced by British surgeons in their most serious operations in civil work. No more skin should be excised than is absolutely necessary; even if badly damaged it can often be saved. In the next place, the operation must be done most deliberately and thoroughly, so that no part of the wounded area escapes treatment. This all means a good deal more time than is required for the opening up and cleansing of the average infected wound which is not suitable for suture, but it is time well spent, especially if the case is one of fracture. On the other hand, operation for the excision and cleansing of small superficial wounds can be done quite quickly, and no class benefits more than these by this method of treatment. It is in the class of slightly wounded, with injuries of the soft parts, or flesh wounds, that early and careful operation yields the highest proportion of success. Hitherto, when wounded are numerous, these patients have habitually been carefully dressed but not submitted to operation. Often many weeks or months have elapsed before their wounds have finally closed, and for all this time they have been inmates of hospitals and frequently confined to bed. Some of them have had serious complications as well. Successful suture makes a complete cure of such patients in a time measured by days or weeks instead of by months.

The benefit to the more seriously wounded is still more obvious. Not only are compound fractures converted into simple ones, but the period of confinement to bed and to the hospital is greatly shortened. The absence of sepsis is well seen in the features of the patients, whose good color tells its own tale. There is none of the general loss of flesh, none of the shrunken and stiff, wooden-like limbs seen after prolonged suppuration, none of the stiffness of all the joints of the affected limb which is so long in recovering. Out of a total of 626 cases, 68 per cent. were successfully sutured and healed by first intention. At the observation hospital 123 wounds have been sutured, with success in 83 per cent. In these three separate areas there is a total of 1,202 cases under various surgeons, with success in about 70 per cent. Moreover, in many of the remaining 30 per cent. there was a very early closure of the wound in spite of superficial suppuration. The success obtained in cases of fracture is also very striking, showing 75 per cent. of successes. The amputation cases at the observation hospital have been few, but they also have been very satisfactory. Of eleven cases all the patients have recovered. Seven were amputations through the thigh, two through the leg, and two were Syme's. Ten out of the eleven healed soundly either after immediate suture or after closure of the flaps on the third or fourth day. One failed to unite, and suppurated. Another very satisfactory result is that the whole of the patients have, so far, recovered whose wounds were sutured at the observation hospital. There has as yet been no death in the 175 patients operated on for suture, whether the latter was successful or not. Yet many of these men were very badly injured. More than 40 of the 175 had fractured bones; 2 of them had torn femoral arteries (but have kept their limbs after ligature of the vessel); 2 had torn posterior tibial arteries; 8 had wounds opening the knee joint, in one of which the patella had to be excised; several had fractures opening the elbow joint; more than 20 had multiple injuries; 2 of them required transfusion of blood. Bowlby does not believe that all these men would have recovered if their wounds had not been closed.

The application of this treatment must remain largely a question of man power from first to last. First, it is only by having enough stretcher-bearers that the British can get in the wounded who cannot walk, and, one must add, enough strong stretcher-bearers. If men are not brought in soon their wounds cannot be sutured, so it is really a race against time and against the microbic infection, which has got the start of both stretcher-bearers and surgeons. Difficulties exist which, though they might not be thought of by the inexperienced, explain why men may arrive too late without any one being to blame. Both many and strong stretcher-bearers are required, and it is difficult to provide too many. It is not clear that delay in reaching a casualty clearing station may be unavoidable. In the second place, primary suture of wounds evidently requires surgeons in proportion to the number of the wounded. The British have already been able to operate on almost all the most serious cases at the casualty clearing stations in recent battles, and one wounded man out of about every three wounded was passed through the room and operated on under an anesthetic. The remaining two thirds were sent to the base, and many of them were in the class of the lightly wounded. In future, the wounds which have been excised but not sutured at the front, as well as probably some not yet excised, will be dealt with by hospitals placed further back than the casualty clearing stations, and thus, if there are enough surgeons, and if wounded are not too numerous, the surgeons hope to be able to insure that a majority of all suturable wounds shall heal by first intention. If their expectations are realized patients will not be so long in the hospital, and there will be less strain on staffs at the bases both in France and in England. Much depends on the incidence of the wounded and on the supply of surgeons. Bowlby puts in a special plea for plenty of medical officers in France.

2. **Gunshot Wounds of Abdomen.**—One hundred and fifty consecutive operations for penetrating abdominal wounds are analyzed by Charles. He points out that difference of opinion sometimes arises as to whether a gunshot wound of the abdomen involves the peritoneal cavity or not; indeed it is sometimes impossible to tell without a laparotomy, for the signs and symptoms usually associated with these cases are not constant. Experience will usually settle the point in each particular case. The following points taken collectively are important: 1. Position of the injury: It is first necessary to determine if possible the direction of the track. The entrance and exit wounds give an idea of the path of the missile and the structures likely to be involved. The absence of an exit wound does not necessarily mean that the foreign body is lodged in the abdomen. The possibility of its being buried in the parietes must be excluded. 2. The facial expression is usually one of anxiety. 3. Pain is not of great value, and may or may not be present. 4. Tenderness is a very constant and reliable sign. 5. Rigidity, or the absence of it, is often most misleading. 6. The pulse varies in rate; it increases directly with the gravity of the intraperitoneal lesion, and gives an important basis for prognosis. 7. Vomiting is usually present, but not necessarily. Thirst is a most distressing symptom. Roentgen-ray localization affords the most useful guide to the diagnosis of penetrating wounds of the abdomen.

The cases on their arrival at a casualty clearing station may be classified for the purpose of treatment, according to their general condition and irrespective of the class of wound, as follows: 1. In a dying condition, when nothing can be done except to relieve pain and thirst. 2. Showing varied degrees of collapse, but capable of resuscitation. 3. In good condition and operable. Preoperative treatment principally consists in treatment for shock. In Charles' opinion operation should not be undertaken before the patient has recovered from shock. In patients suffering from shock and hemorrhage Charles has often waited six hours or more, taking the risk of further hemorrhage, with results that have justified the delay. Provided the patient is warm, operation is done at once. Saline is given on the table during the operation.

4. **Infected War Wounds Treated with Magnesium Sulphate.**—During the past year Morison has been using a preparation of magnesium sulphate, made of the consistency of cream, as soon as the patients arrive in the hospital. To make the conditions as closely as possible resemble those that exist in a casualty clearing station, about 100 cases were dealt with as follows: The dressings with which the patients arrived in the hospital, most of which were applied from two to five days previously, were removed. A culture was taken of the organisms—aerobic and anaerobic—present in smears from the wound, and without any preliminary cleansing of the wound itself or of surrounding parts; magnesium sulphate cream was then applied to the wound under a suitable dressing. The dressing was left untouched for from three to ten days. Bacteriologic and clinical examination was then made of the discharges and the wound. The results have been encouraging. The cream is prepared in the following manner: 1.5 pounds of magnesii sulphas exsiccatus are mixed with 11 ounces of glycerin phenol (1:10). The dried magnesium sulphate is in the form of a fine white powder, which contains 12 per cent. less water than the ordinary. The glycerin phenol is put in a hot mortar and the sulphate added, slowly stirring and mixing with a warm pestle all the time. The result is a thick white cream, so hygroscopic that if exposed to the air it rapidly absorbs moisture and becomes fluid. It must be preserved in a covered jar. The phenol was first added for its analgesic properties, as it was thought that this application without it would be painful. Morison found this precaution to be unnecessary, as the only discomfort of which the patients complain when phenol is not present is that the cream feels cold for a short time after its application.

The wound is packed and thickly covered with the cream, and the dressing of gauze and cottonwool is left unchanged for from three to eight days. A profuse discharge of serum takes place, so that more wool may have to be applied over and around the original dressing. On removing the dressings, any discharge there may be is seropurulent, escapes easily, and the wound surface is covered with bright red granulations, filmed over by a thin layer of greyish lymph containing a few pus cells. A similar dressing is again applied spread thickly on gauze. In the case of deeper wounds, such as fractures, the cream is syringed into the deepest part of the wound by passing a piece of drainage tube attached to the syringe into it, and filling the wound with cream. More cream spread on gauze is applied to the surface of the wound. After a few dressings in this manner, in the case of superficial wounds, a bright red granulating surface presents, covered by a greyish film of lymph. The dressing is now changed to magnesium sulphate solution for a few days, when the edges of the wound are either brought together with sutures, or skin grafts are applied under local anesthesia.

In deeper wounds in which a fracture is also present, after three or four applications of the cream, at intervals of three to four days, the patient is anesthetized, the wound is freely opened up, loose pieces of bone are removed, it is washed out with ether or petrol, then dried with gauze mops and smeared thoroughly with bipp or X. Y. Z. paste—xeroform (bismuth tribromphenate), hydrargyrum ammoniatum, of each equal parts; liquid petrolatum to make a paste. The deeper layers of the wound are brought together with catgut sutures, and the skin edges with retention sutures of double bipped silk passed about 1 inch from the margin and tied over a dossil of gauze on each side spread with one or other paste. In some cases before the sutures are tied the cavity is filled with magnesium sulphate cream. The sutures prevent a too rapid escape of the magnesium sulphate cream by osmosis. The guides to closure of the wound are bacteriologic findings of the discharge and the amount and clinical nature of it.

18. **After-Effects of Gunshot Wounds on Joints.**—At the Croydon War Hospital an examination under anesthesia is undertaken in every suitable case in which there is any undue interference with the function of a part or in which some movable obstruction exists and where the roentgenogram shows no lesion likely to be aggravated by the examination or by the subsequent manipulations. The extent of the disability is determined, the limitation of movement defined; any fibrous adhesions are broken down and any obstruction capable of being rectified is overcome. No undue force is ever used, and in no case has inflammation or notable swelling followed, while considerable improvement has, in practically every case, resulted. Out of the first hundred cases thus operated on seventy-five returned to full duty. Massage is commenced within a few days of the manipulations, light in character if pain be present, more firmly otherwise. The pain from the breaking down is usually quite transitory and passes off in the course of an hour or so. Massage and radiant heat are continued for a week or ten days, when exercises by weights and pulleys are commenced. During the first week of these exercises massage is still continued, as the muscles are often inclined to be painful from their unaccustomed use. In certain cases a previous attempt had already been made, and some disturbance caused, in consequence of which the joint had been immediately placed at rest on a splint. The disturbance may possibly have been immediately due to a too early interference, or a too vigorous attempt at movement. Early interference is deprecated, where there has been destruction of tissue by gunshot or shell, followed by suppuration. No joint should be forcibly manipulated when a discharging sinus exists in its near proximity.

Romer says that in moving joints under anesthesia the failure to obtain a full range of movement is of small importance, if the limitation is due to contracted muscles or induration round the joint, and undue force should not be exerted for this achievement. After-treatment will usually regain the full movement, if sufficient freedom has been obtained under the anesthetic to enable the controlling muscles to act on the joint. The less force it is found necessary to employ the better is the prognosis of a good result. Joints blocked by dense inflammatory products do not respond well to forcible manipulation, but in suitable cases of joint stiffness restoration of function is materially hastened by its employment. The treatment given in the massage department includes radiant heat, hot-water and contrast baths, the ordinary massage manipulations and movements, besides the faradic, galvanic, and sinusoidal currents, and ionization. The treatment is given daily, in length varying according to the case, the minimum duration being half an hour. Special exercises supplement the massage, and are adapted to strengthen still further the weakened muscles and muscle groups, as well as to increase the range of joint movements. The weakened or injured muscle or groups of muscles are encouraged to act, and assisted in the action by the descent of weight, which has been raised by the sound antagonistic muscles. The repetition of this movement at first is strictly limited and the weight a light one, but as progress is made the weight is increased and the exercise lengthened. As further improvement is effected the range of exercises is extended, and becomes inclusive of those in which the weight, light at first and heavier afterward, is lifted by the affected muscles.

In Romer's opinion voluntary exercises performed on a pulley machine are in every way superior to the automatic movements obtained by mechanical machines based on the Zander type. For if a joint is so stiff that it cannot be moved or be encouraged to move voluntarily it is quicker to loosen it once and for all under anesthesia. In addition to these various forms of exercise swimming is found to be an agreeable and useful remedy in most cases of crippled limbs. As soon as the weakness of the special muscles or muscle groups has been overcome, and in cases in which there is no specialized muscular debility the proper use of ordinary gymnastic apparatus proved of material assistance in restoring the general tone of all the muscles and of thus taking part in the restoration of the lost function. The playing of games such as the throwing of the medicine ball, also aids in regaining the rapidity of action. It is surprising to notice how quickly men seem to forget the existence of disability in the excitement of games.

23 Differential Diagnosis in Abdominal Lesions. W. J. S. McKay.—p. 187.

20. **Study of Duodenal Ulcer.**—The occurrence of the peptic ulcer (gastric and duodenal) is explained by Jona as being due to the inhibition of the flow of saliva, pancreatic juice, succus entericus, and bile when these should be normally set up. This inhibition is caused by the absorption of toxic substances, which can be experimentally proved to have this inhibitory action. The exact site of ulceration depends on some local condition. Jona claims that duodenal and gastric ulceration can be prevented by preventing the absorption of toxins, abnormal products of tissue breakdown (as in burns) or the products of bacterial action, parasitic or saprophytic. When the ulceration is already established, he would not perform any side-tracking operation, such as gastro-enterostomy, without at the same time making some attempt to find out the cause of the condition and remove or remedy it.

29 *Malaria in Troops in Macedonia. P. Armand-Delille, G. Paisseau and H. Lemaire.—p. 675.

24. **Painful Echinococcus Disease of the Liver.**—Chauffard remarks that the hydatid cyst in the liver is not a disease of the liver, properly speaking, but an accidental parasitic graft which develops slowly and insidiously, not attracting

attention until the size and weight begin to annoy. Pain does not form part of the clinical picture, but there may be an inflammatory reaction with development of adhesions which bring pain, and may even simulate gallstone mischief. The pain is a warning of superposed infection, as otherwise the parts yield to pressure, without pain. A number of cases are described which led to erroneous conclusions. In one physician of 38 a catarrhal jaundice and what seemed to be gallstone colics compelled an operation, but no gallstones could be found. The common bile duct was enlarged but was not opened. At a later operation, the common bile duct was found full of hydatid cysts and a large cyst found in the liver was evacuated. The findings indicated primary localization of the parasites at both these two points. In differentiation from gallstones, the shape of the enlarged liver, its anterior outline, differ materially from what we see with gallstones. If the liver is not enlarged, differentiation may be difficult, especially if the cyst is pressing on the lumbar plexus or other nerves, deceptively simulating gallstone colic. Or the toxins generated in the cyst may induce reflex pain.

25. **Dysenteric Abscess of the Liver.**—Job and Spick analyze their experiences with ninety-two cases of dysenteric abscess of the liver in northern Africa. Europeans are affected more than the natives, and the disease is exceptional in the blacks. In an ameba country, enlargement of the liver should always suggest dysenteric abscess, although the patient may not have any history of dysentery. In eighteen of their ninety-two cases there had been no known dysentery symptoms. Polymorphonuclear leukocytosis is an important sign of dysenteric abscess. Radioscopy and puncture aid in the diagnosis. When discovered early, emetin may cure after the pus has been evacuated. Injection of the emetin directly into the liver is advocated, besides. When all else fails, operative treatment should be considered after thorough emetin treatment.

26. **Meningeal Hemorrhage from Shell Air Shock.**—Guillain and Barré found evidence of meningeal hemorrhage in twenty cases of shell air concussion without direct contact. The clinical symptoms were confirmed by the hemorrhagic lumbar puncture fluid.

27. **Disordered Digestion in Soldiers.**—Péhu and Daguet report that roentgenography failed to reveal any organic basis for the chronic dyspepsia in 137 of 381 cases. In 139 others purely functional disturbances were observed; in 27 accompanied by much ptosis. In 32 actual ulcer or cancer was found; the other men were convalescing from wounds.

28. **Contracture or Paralysis of the Feet.**—These writers have published a similar study of the hand; here they discuss psychoneuroses manifested in talipes varus. They regard these crippling deformities as made up of several elements, including an actual traumatic contracture or paralysis, a superposed element of hysteria, and superposed nutritional disorders from the long immobilization and abnormal position. But the mind is the main element involved in the perpetuation of the deformity. When influence can be brought to bear on the mind sufficient to break up the vicious circle, the whole trouble may disappear at one stroke. These acrocontractures and acroparalyses seem to be as curable as any other purely psychoneuropathic disorders, with or without secondary disturbances. Hence the importance and practicability of prophylaxis.

29. **Malaria in the Macedonia Expeditionary Force.**—Delille and his co-workers declare that the epidemic of malaria that has affected the armies operating in Macedonia forms, if not the most important, at least one of the most important military epidemics known in history. Not since the armies of Xerxes were decimated by malaria in that same region, has there been a situation comparable to that of these modern forces in the Macedonian valleys and marshes. The extreme gravity of the infection, the early and large proportion of pernicious cases, the apparent failure of preventive doses of quinin, the prevalence of malignant tertian malaria—the quartan type was rare—and the frequency of hemoglobinuria, were special features.

36. **The Rights of the Wounded and of the Surgeon.**—Delmas remarks that as soon as the soldier enters the hospital, he steps out from under military discipline, and yet the hospital authorities have no jurisdiction over him. He can accept or refuse needed operations, injections of drugs, etc., at his own will. But almost invariably the wounded or sick soldier trusts absolutely to his surgeon or physician, so long as no foreign element modifies this grateful confidence. There can be only two reasons for refusal to consent to needed measures, fear or ignoble motives—fear of pain, of the anesthetic or of a fatal outcome, and fear of recovery and being sent back to the firing line. Delmas does not hesitate to call the man in the latter case a deserter. The physician or the surgeon should appeal to the man's regimental commander. The man should be sent back to his regiment with a report of his refusal, unless there are grave reasons against his being moved. The presence in the hospital of one such refuser saps the confidence of the other patients. The matter is thus placed in the hands of the military commander who can apply disciplinary measures. The regulations specify that no operation, properly so-called, especially if general anesthesia is required for it, can be done without the assent of the patient. He must be warned that his refusal will be duly considered in determining the amount of his pension. In any event, it behooves the surgeon and physician to write out a detailed report of the incident. under all circumstances. This will fix the respective responsibilities of the surgeon, the wounded and the pension treasury.

38. **Intermittent Claudication.**—In the two cases described, the inability to continue walking came from pain, not paralysis. There seems to be grounds for assuming that, besides the ischemia resulting from the causal arteritis, there is some superposed circulatory disturbance, and this can be only some spasm of some vessel. The facts that the limb grows cold and the oscillometer shows reduced blood supply sustain this assumption of spasm of the vessels. After resting a while, the limb grows warm again and the oscillometer shows renewed circulation. The exercise in walking brings more blood to the region. The blood meets with the obstacle of the endarteritis, and the resulting pressure on the walls

of the vessel above sets up a reflex pain and spasm, as when the catheter is arrested by stenosis in the urethra or esophagus. In one of the cases described the colic pain ran from the groin to the sole. Vascular spasm is also an element in the clinical picture of certain war contractures of hand or foot. Treatment for underlying syphilis or malaria, electrotherapy, massage and superheated air may be indicated in different cases.

40. **Roentgenotherapy.**—This issue of the *Paris Médical* is devoted to roentgen treatment. Weil discusses the general principles involved as modified by the latest experiences. He regards the maximal dose as 10 or 12 H units for the short wave rays, the hardest obtainable, passed through aluminum filters at least 1 cm. thick. With a very small area of exposure, this maximum might be surpassed. Slipping the skin to one side, and crossed-fire exposures might be supplemented by rhythmic swinging of the tube, permitting the rays to fall like an inverted cone on the focus while they are distributed in a circle on the skin. The manufacturers in France have not succeeded yet in realizing a device for this purpose. None of the methods to enhance the local susceptibility to the rays and aid in generating secondary rays have proved effectual.

41. **Length of Exposure.**—Réchou has devised a disk with logarithmic graduation which shows the proper length of the exposure under given conditions of rays, filter, length of spark, amperage and distance from the focus.

47. **Roentgen Signs of Tuberculosis.**—Weil enumerates among other signs the unchanging aspect of the shadow of the apex during breathing or coughing while the rest of the lung grows lighter. If the shadow of one apex clears up some time before that of the other apex, this must be regarded as suspicious, as also the lagging behind of one half of the diaphragm. But the most instructive sign, perhaps, is the fact that with old tuberculosis, tending to fibrous retraction, the apex looks small and pointed, while with active tuberculosis, especially in the young, the congested apex is seen to be larger than normal; the whole lung seems spread out, and the ribs are raised. The ribs make slight or no excursions in either case.

48. **Principles for Preventive Vaccination Against and Bacteriotherapy of Typhoid and Cholera.**—Danysz argues that what we know of the infectious diseases acquired through the gastro-intestinal canal justifies the assumption that those persons alone develop the infection who are unable to digest completely the bacteria they have swallowed, that is, are unable to convert the albumins of the microbes into amino-acids. The course of the infection is determined by the number of bacteria ingested, the intensity and rapidity of the processes of digesting them, and the quantity of normal antibodies already in the blood. By taking into consideration the prevalence of the different types of bacteria, their susceptibility to gastro-intestinal digestion, and the permeability of the mucosa for the products of their digestion, these bacteria fall into four great groups. In diphtheria, the toxin, plus the normal antibodies, acts to cause the disease. When the antibodies are generated in excess, the disease stops. In the gastro-intestinal diseases, on the other hand, the stage of digestion of the bacteria, plus the normal antibodies, forms the period of incubation. The disease proper does not begin until the antibodies are generated in excess. This induces anaphylaxis, and the manifestations of this anaphylaxis form the disease proper. In typhoid, for example, the disease consists of a chronic state of anaphylaxis, or rather, a series of successive anaphylactic crises. Immunity and anaphylaxis are phenomena of every living being, from the microbe to man. A microbe entering a superior organism has to adapt itself to this new environment. It produces an intracellular antibody, then it produces an excess of antibody, and the antibody generated by the host serves as an antigen for the microbe, just as its own antibody is an antigen for the host. The outcome depends on the balance between the degrees of immunity and anaphylaxis of the microbe and of the host organism. When the microbe has fixed a corresponding amount of the host's antibody, on its own intracellular antibody, it is safe so long as it is laved outside by an excess of the host's antibodies. Let the content of host antibody drop below the proportion within the microbe cell, then the cell bursts by an anaphylactic shock. The aim in treatment, therefore, should be to reduce the excess of host antibodies in the host plasma. This can be accomplished by introducing more bacterial antibodies (killed bacteria). The excess host antibodies combine with them and there is no longer any excess of antibodies in the plasma. His practical conclusion is that for all the diseases of gastro-intestinal origin, preventive vaccination is promising, realized by prolonged ingestion of progressively increasing doses of the dead bacteria. The most effectual curative technic would be with specific bacteriotherapy by fractioned intravenous injections or frequently repeated ingestion.

51. **Chronic Lumbar Rheumatism.**—Léri remarks that the prevalence of chronic lumbar rheumatism may be estimated from the fact that at the date of writing there were seventeen cases among the 200 men in his service. The roentgen rays have shown that there is osteophytic proliferation with decalcification of the lumbar vertebrae. There was nothing to suggest syphilis or tuberculosis in any of the men, with one or two exceptions. The disease seems to come and go, each attack lasting from two to eight or ten months; the pain, tenderness and curvature then subside more or less completely. Many of the men had had previous attacks, but the frequency and intensity of the attacks justify classing this special, strictly localized form of vertebral rheumatism as a war disease. Even when the men are seated, in the trenches, they often have to rest their backs against a damp wall. Long marches in mud, with their equipment on their back, also adds to this "pathology of the back." This lumbar rheumatism is not usually accompanied by rheumatism of the joints, but the man stoops over although on reclining he can straighten his spine. Another feature of the cases is the concave outline of the vertebrae, so that they resemble the toy called the diabolo. Sodium salicylate and immobilization have given the best results in treatment to date.

52. **Pulmonary Edema after Skull Wounds.**—Moutier calls attention to the acute pulmonary edema which so often develops and proves fatal in men with war wounds of skull and brain. He explains how this is brought about by pathologic excessive functioning of the suprarenals. This causes the blood pressure to run up, the proportionately higher minimal pressure testifying to the specific vasoconstriction. The current practice of giving epinephrin to the wounded would do direct harm in such cases. Treatment should be that for acute pulmonary edema, that is, venesection. The danger is from the lungs, not so much from the skull wound.

53. **Cavities in the Lungs.**—Mantoux and Maingot give roentgenograms showing different types of shadows cast by cavities, the "porous bread" type, the "hornets' nest" type and the single large cavity type. Nothing suggesting either of these three types was found in 250 "closed" cases of tuberculosis or the suspects.

56. **Masked Dysentery.**—Decrop emphasizes that persisting diarrhea, even if not severe, but accompanied by pronounced weakness, should always suggest amebic dysentery, especially if there has been any intercourse with persons coming from tropical regions.

61 Stenosis of Urethra from War Wound. F. Cathelin.—p. 66.
62 *Genito-Urinary Psychoneuroses. Uteau and Sauvage.—p. 68.

58. **Suture of Severed Nerves.**—The experiences with war wounds of nerves have only confirmed Delorme's teaching that the best results are to be obtained by cutting up to sound tissue and drawing the freshened ends together. This requires loosening up the nerve to mobilize it for a long distance, and placing the limb in a position to bring the stumps as close together as possible. Unless the cicatricial tissue in the nerve is resected up into sound tissue, it acts as an impenetrable barrier, so that mere releasing of the nerve from its cicatricial bed does not modify the resulting paralysis or trophic lesions.

59. **Trophic Lesions After Injury of Nerves.**—Experiments on dogs are described and a number of clinical cases, all testifying to the effect that there are no trophic nerve fibers, properly speaking, but that irritation of a nerve induces the trophic lesion, not suppression of the functioning of the nerve. The wearing off of tissue plus infection may induce lesions suggesting trophic disturbances but they are not true trophic lesions.

60. **Genital Complications of Typhoid and Paratyphoid.**—Seven cases of this kind have been published in France in the last three years, and five more are here reported. The orchitis was on one side only in this group of five. In two of the cases the typhoid and in three paratyphoid B bacilli were found. In two of the last three the lesion suppurated, and in one the suppuration kept up a long time, the testicle actually melting away. There were no other signs of disturbance in the urinary apparatus, so the infection was probably blood-borne.

62. **Urogenital Psychoneuroses.**—Two cases are described in young women that might be called cystalgia and urethralgia. In the cystalgia case the disturbances were ascribed to movable kidney, with possible lithiasis, and nephropexy was done although the exposed kidney seemed entirely normal. Nearly three years later the whole train of symptoms reappeared after some emotional stress; after failure of various medical measures, a course of psychotherapy banished them anew. Symptoms of pulmonary tuberculosis then suggested that the cystalgia may have been to some extent a manifestation of incipient tuberculosis. The success of psychotherapy in this case led to the application of similar measures in the urethralgia case. By a kind of psychanalysis it was ascertained that the trouble was the result of a mistaken comprehension of the anatomy of the region, the young married woman supposing that the vagina and the urethra were a single passage, although she had borne a healthy child. After three weeks of psychotherapy she threw off the urethralgia completely, and has had no return during the five months to date. It had been tormenting her for ten years and she had consulted a dozen physicians and taken all kinds of treatment. Uteau and Sauvage advocate a little hypnosis at first, to get the patient's confidences. This does not interfere with rational psychotherapy to follow at once.

67 *Whooping Cough. O. Cozzolino.—p. 129.
68 *Progressive Ossifying Myositis. G. Caronia.—p. 145.

67. **Contagiousness and Prophylaxis of Pertussis.**—Cozzolino relates that he had 345 children with whooping cough at his dispensary at Cagliari in the first six months of 1913. Nearly 30 per cent. were under 12 months, and only 58.3 per cent. were over 2 years old. His experience confirms the extreme contagiousness of the disease during the primary catarrhal stage; some say it is not contagious after the first week, but he thinks it is better to assume thirty days as the limit. He has never seen contagion of other children from the pertussis children taken into the hospital from the fifth to the eighth week, nor from two in the middle of the third week. None of the children in adjoining beds even developed a spasmodic cough. A change of air and scene is useful in eliminating the nervous and psychic factors which cooperate in maintaining the spasmodic cough. The greater predisposition of girls to pertussis, and the larger number of girls attacked by the disease differ from what we know of acute infectious diseases in general.

68. **Progressive Ossifying Myositis.**—Caronia's case he thinks is the ninety-third on record. His patient was a little girl of 4, otherwise healthy, who had developed bony lumps in various muscles of trunk and arms, the protruding lumps giving the back the aspect of a raised map showing mountain ranges. Several roentgenograms confirmed the diagnosis of progressive ossifying myositis. No benefit was apparent from epinephrin, thyroid, thymus or pituitary extract, as has been the general experience. The literature on the subject is reviewed.

74 Freezing Injuries of the Feet. P. Perazzi.—p. 33.
75 Experimental Lesions of the Pituitary. A. Chiasserini.—p. 44. Continuation.

69. **Isolation of Cholera Vibrio Carriers.**—Mazzolano remarks that the *locali contumaciali,* as the quarters for sheltering carriers are called, are proving one of the most effectual of the measures for preventing the spread of cholera. The public appreciate the necessity for this isolation, and it meets with no opposition. The emission of the vibriones is irregular, but as a rule it is continued in convalescence not later than the tenth or twelfth day. Of the 58 carriers or suspects thus interned at Sassari, some showed no signs of the vibrio for three or four days and others not till later than this. They disappeared from the stools of 20 carriers in five days, 12 carriers in ten days, 7 carriers in twenty days, and in 9 others between the twentieth and thirty-fourth days. The intermissions with negative findings were from three to sixteen days in length. One convalescent had five positive periods. Cholecystitis for which the vibriones are responsible may be the cause, or there may be actual reinfection. This suggests the necessity for special measures addressed to the cholecystitis, and to warding off secondary or repeated infection. Hexamethylenamin seemed to hasten the disappearance of the germs.

70. **Test for Albumin in Body Fluids.**—Leone's reagent superposes the precipitating properties of three precipitants. He pours into 100 c.c. of distilled water, heated, 10 gm. of potassium bichromate. After filtering and cooling, 100 drops of glacial acetic acid are added and, a few minutes later, 100 drops of a 25 per cent. solution of pure sulphuric acid. Of the reagent thus prepared, 5 c.c. are transferred to a test tube. Then the urine or other protein solution under examination is added with a pipet. At the zone of contact a whitish ring forms. When there is much albumin present, delicate whitish threads can be seen extending down into the fluid below like wisps of smoke. The reaction occurs at once or in four or five minutes. There may be further two zones of precipitation, separated by a limpid zone. The reaction is

not modified by the presence of iodin, mercury or salicylates in the urine. From the intensity of the whitish ring, its height and the rapidity with which it forms, the proportion of albumin present can be estimated. If there is no albumin, a brown ring forms from the combination of the urea with the reagent. When the whitish ring forms at once, with only a few c.c. of urine, there is always more than 0.5 per thousand albumin present. If the ring takes several minutes to form, there are only a few mg. of albumin.

71. Prothesis for Paralyzed Leg.—The prothesis described with illustrations is designed to correct paralysis of the external popliteal nerve.

Riforma Medica, Naples

Feb. 23, 1918, **34.** No. 8

76 *Extreme Meteorism in Soldiers. A. Cecconi.—p. 143.
77 *Operative Treatment of Hypospadia. G. Gianturco.—p. 147.
78 Early Diagnosis of Sciatica. A. Rocavilla.—p. 149.

March 2, 1918, **34.** No. 9

79 War Surgery and Ordinary Surgery. D. Giordano.—p. 162.
80 *Linear Stethoscope. G. Tomasinelli.—p. 165.
81 Tuberculous and Syphilitic Sigmoiditis. G. Cicconardi.—p. 169.

76. Big Abdomen in Soldiers.—Cecconi remarks that there are three types of meteorism in soldiers, free from digestive disturbance, to explain the extremely distended abdomens. In one type the trouble is caused by a hysteric, tonic spasm of the diagram. In the second type the meteorism is factitious, the men merely swallowing air to induce it. In the third type the meteorism is more in the flanks, and it occurs intermittently, reaching its height in twelve or sixteen hours and lasting for a few hours or days. Roentgenoscopy showed that the meteorism was mainly in the colon. The respiration in these cases was shallow, and this, with the pronounced bradycardia, gave the clue to the cases as vagotonic phenomena.

77. Operation for Hypospadia.—Gianturco says that the war has revealed that hypospadia is more common than formerly believed. About 0.5 per cent. of the men seem to be affected with it. He has modified the usual technic for penile hypospadia, and prefers spinal anesthesia for it. He cuts a torpedo-shaped flap in the skin, extending from the urethral opening to the tip of the penis. Then a triangular flap, with the point proximal, is cut below and removed. The sides of the torpedo-shaped flap are brought up over a greased catheter and sutured to make the new urethra; the proximal end is sutured to the freshened stump of the natural urethra. The skin of the penis is then loosened and brought up to cover the new urethra and likewise the raw triangle left beyond the old urethral opening. The result is a single new urethra, with a linear suture in the lower aspect of the penis. The appearance and functioning have been highly satisfactory in the cases in which he has applied this method.

80. Linear Stethoscope.—Instead of a *round* opening, Tomasinelli has the stethoscope end in a long bar, the whole thus forming a T. He declares that the findings are more instructive along a line than in a circle.

Rivista Critica di Clinica Medica, Florence

Feb. 16, 1918, **19.** *No. 7*

82 *Vaccine Therapy of Typhoid. F. Micheli and G. Quarelli.—p. 73. Commenced in No. 5, p. 49.

82. Heterologous Vaccine Therapy of Typhoid.—Micheli and Quarelli expatiate on the success of vaccine therapy of typhoid and paratyphoid as an appreciable conquest in the line of therapeutics. The attenuation of the clinical picture and reduction of the mortality (from 30 to 11 per cent. in Ishikawa's series and from 12 to 5 per cent. in Holler's) testify to the efficacy of this bacteriotherapy. As typhoid bacilli are so virulent, and as certain other bacilli seem to be fully as effectual for this vaccine therapy, they advise using bacteria of a different species rather than typhoid bacilli. Paratyphoid bacilli cannot be used as they seem even more toxic than true typhoid bacilli. The vaccine used must be exactly dosable, with an action that can be accurately graduated, and that is constant. These requirements are filled by vaccines desiccated in a vacuum and kept in fused vials. The writers, and also Moreschi, have been using with great satisfaction vaccines of this type for intravenous preventive vaccination. Small doses, eventually repeated after two or three days, proved most effectual in their experience. They take as a rule, for the initial dose, the amount of heterologous vaccine which in healthy persons induces a manifest thermic reaction. With typhoid bacilli vaccine they take twice this, on account of the greater tolerance in typhoid for the specific endotoxins. Experience has shown that patients refractory to small doses are equally refractory to the largest ones. Contraindications are cardiovascular insufficiency, grave kidney complications, diffuse pneumonia and menace of hemorrhage and perforation of the bowel.

The vaccine used in their tests of this intravenous heterobacteriotherapy was deuteroalbumose, meningococcus vaccine and cholera vaccine. The best results in the twenty-five cases of typhoid or paratyphoid were obtained with cholera vaccine, as the doses of this can be accurately graduated, while this vaccine is only slightly toxic. It is prepared by the Loeffler method (sterilization with dry heat at 100 or 110 C. of a loop desiccated in a vacuum). None of the patients were given more than two injections. The dose was from one-fifteenth to one-fifth of a standard loop, in 1 c.c. of physiologic solution. A chill always followed in from twenty to forty-five minutes. In three of the twenty-five cases a single injection was followed by definite defervescence. In 40 per cent. of the cases defervescence followed in the first to the fourth or seventh day. In another 40 per cent. the temperature only gradually subsided to normal, although the general condition showed equal improvement. Only one patient died, and this was on the thirty-fourth day, long after the vaccine had been given. There was a relapse in 20 per cent. of the cases, about the usual average. These experiences are compared with the work of others in this line.

Anales de la Facultad de Medicina, Lima

January-February, 1918, **1.** No. 1

83 Classification of Liver Diseases. E. Odriozola.—p. 1.
84 Grahamella Brumpti n. sp. Ribeyro and del Aguila.—p. 14.

88 *Insanity in Peru. H. F. Delgado and C. A. Bambaren.—p. 78.
89 Bacteriology of Ozena. J. A. Monteverde.—p. 112.

88. Insanity in Peru.—Delgado and Bambaren analyze the experiences at the Lima Hospicio de Insanos. The proportion of paranoia cases has increased in the last twenty-one years from 12.12 to 22.26 per cent. They note that the drunkards who get into the police courts seldom wind up in the asylum. The majority of the candidates for the asylum are those who drink but not to the point of visible intoxication. Some intercurrent disease, moral or traumatic shock or exhausting fatigue opens the portal to mental disease for which there is some constitutional predisposition. The effect of habitual drunkenness shows on the offspring. In prophylaxis they suggest sterilizing by means of the roentgen rays. This would avoid the drawbacks of other methods of sterilizing those unfit for procreation. They remark that this procedure seems so reasonable that they wonder it has not been applied. They have not been able to find any reference in accessible literature to its use for this purpose.

Prophylaxis of the mental causes of insanity is a question of education. The majority of psychoses are rooted in some internal conflict possibly early in life, hence wise training of the young in useful habits and adaptation of the child's mind to real life are the most solid guarantees of mental balance in the future. The writers quote freely from recent articles in The Journal, and reiterate that heredity is not an immutable law; its effects can be annulled or attenuated as they occur in plastic living beings who can be molded and trained. Peru has already an efficient system of medical school inspection and this promises to be of great aid in prophylaxis of insanity.

an opening close to the pylorus, and also the necessity for closing the pylorus, and doing it effectually. If the pylorus is left open, food passes out through it and the food may be returned to the stomach, thus unnecessarily overburdening it. But the principal reason for closing the pylorus is that when food is passed along into the duodenum, by reflex action not only the pylorus is closed but the evacuating movements of the stomach walls slow down. With the pylorus sutured to close it once for all, this retarding reflex does not occur, as it is not elicited by the jejunum. The chance of the vicious circle is also less with the pylorus shut off. Another argument in favor of closing the pylorus is that the duodenal ulcer thereby is spared the repeated irritation from the acid gastric juice.

110 *Pseudoleukemia. J. Nordentoft.—p. 225. Concluded in No. 10, p. 298.
111 *Protein Therapy in Eye Diseases. C. L. Andersen.—p. 244.

110. **Roentgen Treatment in Pseudoleukemia.**—Nordentoft reports fourteen cases of Hodgkin's disease or other forms of pseudoleukemia. The tumors were rapidly progressive, as a rule, but under roentgen treatment they melted away. After failure of all other measures, this vanishing of the symptoms and return of apparent health within a few days are most amazing. The disease is not conquered, however; constant recurrence is the rule, but there may be long intermissions and the recurrences generally subside equally promptly under renewed roentgen treatment. The greater the susceptibility to the roentgen rays, the graver the outlook; the more frequent, the more rapid and the more malignant the recurrences. There are a few complete cures to the credit of the roentgen rays, but they are extremely rare, and Nordentoft thinks that in many of them there was a mistake in the diagnosis. In his experience, two of his fourteen patients seem to be cured, but the diagnosis of a mediastinal tumor may have been erroneous in one case; the hemorrhagic pleuritis and adhesions may have been of tuberculous origin. In the other case the diagnosis of Mikulicz' disease seems more probable than pseudoleukemia. No other proliferation of lymphoid tissue was to be discovered except in the parotid glands, and the tumors in them had developed very slowly and were apparently benign. In none of the other cases was a cure realized or even to be anticipated. But the long intermissions between recurrences are equivalent to a cure in many cases. Only one of the total fourteen patients seemed to be refractory to the roentgenotherapy. Necropsy in this case showed necrotic processes for which the roentgen rays may have been responsible. In one young man a tumor in the neck, as large as a man's fist, subsided within a day. The exposure had been made at noon and by evening the subjective and objective improvement was pronounced. One girl of 11 with a large tumor masking the shadow of one lung entirely, gave normal roentgen findings with roentgenoscopy two weeks later. But the toxic action from the subsidence of this tumor was so great that the child died, and the conclusion seems inevitable that the roentgen exposure of the tumor was responsible for the fatality. An interesting feature of the roentgen treatment in some of these cases was that unexposed tumors, at a distance from the one being given the roentgen treatment, subsided along with it. This suggests that possibly the blood may acquire a weak radioactivity, sufficient to act on extremely susceptible tissue. But Nordentoft's experimental research on dogs failed to show any such action even when the negative plate was exposed to the blood for days at a time.

111. **Protein Therapy of Eye Disease.**—Andersen reviews the history of parenteral protein and nonspecific vaccine therapy and summarizes recent experiences in this line reported in Germany. P. V. Szily and A. Sternberg are very enthusiastic over the brilliant results obtained with a typhoid vaccine in gonorrheal ophthalmia, and R. Müller with parenteral injection of milk. Frozier and Darier have also reported good results from diphtheria antitoxin given in eye diseases. In contrast to the fine results reported by others, Elschnig called attention in the last half of 1917 to two cases of gonorrheal ophthalmia in which after three injections of milk the central portion of the cornea was cast off, with prolapse of the iris or, after two injections of milk, the surface of the cornea showed infiltration and casting off of the superficial layer. He warned that we cannot trust absolutely to the "magic action of this method of treating gonorrheal ophthalmia."

112 *Reduplicative Paramnesia. G. Elander.—p. 161.

112. **Reduplicative Paramnesia.**—This term or the expression, *déja vu* phenomenon, is used to designate the sensation sometimes experienced that the incident has been lived through before. It is not very uncommon for persons to have a vague feeling that the persons or incident in question has already been witnessed before. Elander describes a peculiarly pronounced case of this kind in a young man with incipient dementia praecox, admitted to the psychiatric clinic for the first time, who was convinced that he had been in the clinic before, some years ago. Elander explains this illusion of memory as a multiplying of the actual impression. The young man lost this reduplicative paramnesia in a few months, but the dementia praecox continued its progressive course.

117 Movable Cecum with Ileus and Perforation. S. Felding.—p. 301.

114. **Dermatitis from Safety Matches.**—Rasch has had seven men apply to him during the last four months for treatment of a skin disease resembling a mild burn on the thigh, in size and shape corresponding in each case to the trouser pockets. The hands, fingers and eyes also displayed analogous lesions. All were in the habit of using matches of a certain make and carried the boxes in their trousers pockets. The striking surface on the match box responded to the Mitscherlich test for poisonous white phosphorus. The matter is still under investigation, but all the symptoms permanently subsided when these matches were discarded and other makes used. Since Rasch called attention to this dermatitis from safety match boxes, a number of similar cases of this "match eczema," as it is called have been reported in Denmark.

115. **Progression of Myopia.**—Blegvad has been investigating the present condition of 155 adults with myopia given correcting glasses before they were 16. He tabulates the findings in 87 cases traced with special care, some examined several times. Of the 50 with full correction, the myopia had continued to progress in 76 per cent. as also in 70 per cent. of the 37 not given full correction. The average progression percentage was 0.44 D. for the full correction cases and 0.33 D. for the undercorrected. From these and other data presented, he concludes that correction has no influence on the progressive course of myopia. The amount of progress of the myopia decreases with age. Near work increases the tendency to myopia and stimulates its progress. This explains why those who leave school at about 16 and do not use their eyes much thereafter find their myopia keeps stationary, while in those who keep on studying or do much near work the myopia continues a progressive course. His charts and curves confirm that the earlier the myopia develops, the greater the degree liable to be reached. Also that heredity and near work explain the prevalence of myopia in all classes of society.

A SURGEON'S IMPRESSION OF TRIGEMINAL NEURALGIA

BASED ON EXPERIENCES WITH THREE HUNDRED AND TWO CASES

CHARLES H. FRAZIER, M.D.
PHILADELPHIA

There is nothing obscure about trigeminal neuralgia save its origin. The patient has made the diagnosis before the surgeon is consulted, and treatment, to be effective, must include either alcoholic injections or the radical operation. In these few words have been summed up the essential features of this unique lesion of the sensory system.

True trigeminal neuralgia must not be confused with a peripheral neuritis initiated by some infective focus in tooth or sinus, or with the neuritis of toxic or obscure origin. One occasionally hears or reads of the cure of trigeminal neuralgia by the drainage of a sinus, by an intranasal operation or by the removal of an infected tooth. I have never seen or operated on a patient in a case of the major type of trigeminal neuralgia in which there was any reason to suspect any one of these lesions as the exciting cause.

Were I to write on the pathogenesis of the disease, I should describe it as a disease of central, that is, of ganglionic origin, and should hypothecate a lesion in the nature of sclerosis. These are matters, however, of a speculative nature, and I shall not deal with them now. If accepted, they would serve this one useful purpose: Vain attempts to find peripheral lesions as a cause would be abandoned, and patients would be spared many sinus operations and the extraction of a majority of sound teeth in the upper and lower jaws. Most of my patients have been victims of these vicious practices before they came to me for treatment.

The facts presented in these pages are the outcome of my experience with 302 cases of neuralgia of the trigeminal nerve. This includes thirty-nine peripheral operations, ninety-nine alcoholic injections, 130 intracranial operations, and thirty-four cases that were not treated.

The trigeminal neuralgia herein discussed has many typical and characteristic features. To distinguish it from other expressions of pain in the trigeminal distribution, we might call it "surgical" neuralgia. Rarely beginning before the fourth, or more frequently the fifth decade of life, and being only exceptionally bilateral, the pain is first experienced in the second or third division and usually in the terminal distribution of the infra-orbital or the mental nerve. Often two divisions, the maxillary and the mandibular, are eventually involved, and, in a minority of cases, all three divisions. Surgical neuralgia is a disease characterized at first by attacks of a few weeks' duration, with remissions of several months. The attack itself is made up of paroxysms and remissions. The pain is shooting, darting, tearing, being likened sometimes to a red-hot iron boring through the bone. Between the attacks the patient is so absolutely free from pain that his spirits are buoyed up with the false hope that the disease has run its course. But as time goes on, the attacks become more frequent, the remissions shorter, the pain more racking. With few exceptions, surgical neuralgia is not a self-limiting disease. It usually does not die out with age, but gradually beats down the patient's morale until he becomes a supplicant at the surgeon's feet.

PRINCIPLES GOVERNING TREATMENT

It is the treatment of trigeminal neuralgia with which this paper is chiefly concerned. There are no grounds for discussing any method of treatment other than alcoholic injection or the avulsion of the sensory root. The surgeon is spared the necessity of discussing other methods of treatment, since, by the time the patient consults him, all the useless remedies — and they are innumerable — have been tried and have failed, and what reserve of morale or funds the patient may have stored up has, in many instances, been exhausted.

Under what circumstances should the alcoholic injection be recommended, and under what circumstances, the operation? The answer to this question must be qualified by the circumstances themselves. We might divide the patients into two groups, in the first those who have long been sufferers, and in the second, those in an earlier stage of the disease. To the latter group I state the facts baldly. The alcoholic injection is of only transitory effect. Properly given, it will arrest the pain immediately and absolutely, and for an average period of nine months. It is in no sense of the word a permanent cure.

The radical operation assures absolute and permanent relief. When I let the patient choose, after presenting the facts to him, he usually chooses the injection. The injection given, he leaves, pitifully grateful, and encourages himself to believe that this is the end of his suffering. But before the year ends, the pain returns. He fights it out for a while and then returns submissively for another injection. Three or four years pass, with as many injections, and either because the injections are becoming less effective, or — and this is the more potent influence — because his courage is failing, the patient, despairing of permanent relief, will have no more injections and wants the operation. This I should say is a very fair analysis of the psychology of the subject of this disease.

Turning now to the second group of patients in whom the disease is of long standing, that is, from five to ten years, we find the situation very different. For this type of patient there is only one acceptable treatment, namely, the radical operation. Sometimes he has had his alcoholic injection experience; it has served him in good stead for a while, but it is losing its influence and he dreads another attack. This patient's invariable comment after the operation is, "Why didn't I have the operation in the first instance and be spared the suffering in mind and body and the years of recurrent attacks and alcoholic injections?" The physician-patient is usually more emphatic in his expression than the layman, and yet, in the early days of his attacks, his mind was not prepared to accept the proposal of a radical operation.

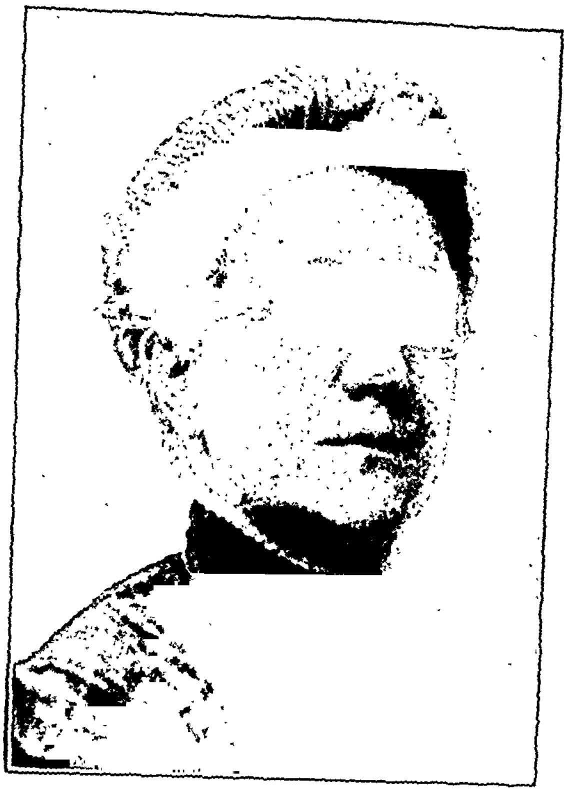

Fig. 1.—Cosmetic results in patient after operation. The incision is entirely within the hair line, hidden from view.

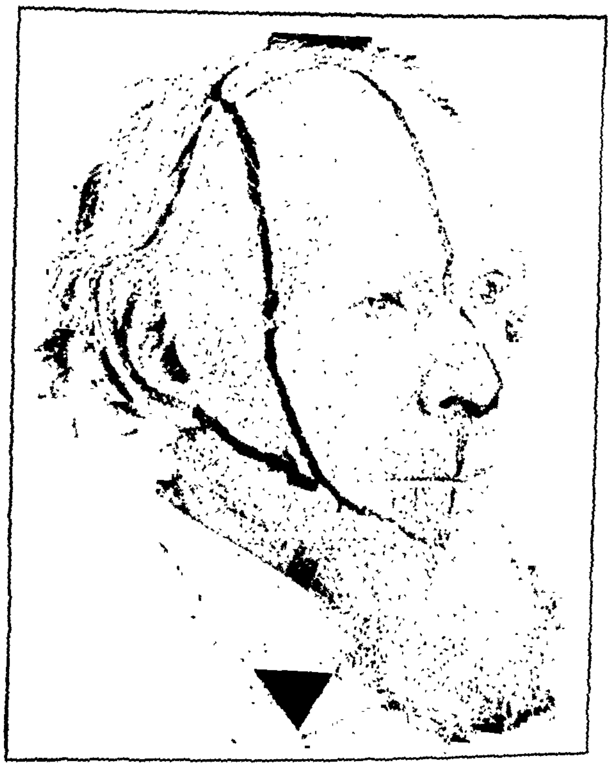

Fig. 2.—First patient on whom the author's operation, "avulsion of the gasserian ganglion," was practiced. The larger area shows the line of regional anesthesia immediately after the operation, and the more restricted area fifteen years later. This contraction of the anesthetic region is not uncommon, although there is never any variation of the line of anesthesia dividing the territory supplied by the trigeminal nerve on one side and that on the other. The nerves of the cervical plexus evidently compensate to a greater or less degree for the loss of sensation in that portion of the trigeminal distribution along the margin of the lower jaw, in front of the ear and in the temporal region, chiefly in the distribution of the mandibular division.

I have said that there are only two methods of relieving a patient with trigeminal neuralgia, the alcoholic injection and the radical operation. Like all rules, this has an exception. There are a few cases in which the pain is limited to the distribution of the supra-orbital nerve. Alcoholic injection of this branch is not very effective; peripheral resection of the nerve may with propriety be employed at first. The intracranial operation in the course of time is usually inevitable. With this exception, the peripheral operation has been altogether replaced by the alcoholic injection. There are, to be sure, certain conditions which might make it unwise to recommend the radical or intracranial operation. A patient whose condition is manifestly unfit for any radical operation is not a fit subject for an operation on the ganglion, and very old people, near the eighties or still older, whose expectation of life is short, may be made comparatively comfortable with alcoholic injections for their few remaining years and spared the risk or discomfort of operation.

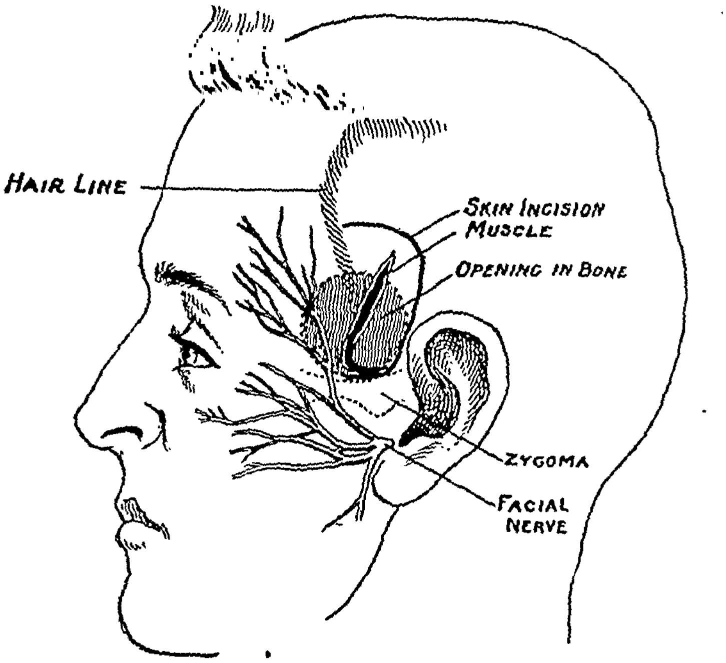

Fig. 3.—Relations of incision to the upper branch of the facial nerve. It is most important that the upper branch of the facial nerve be conserved; otherwise disastrous results might follow from the inability of the patient to close the eyelids. The old-fashioned horseshoe incision assured no protection to this branch.

Having stated very briefly the principles governing the treatment of trigeminal neuralgia, I shall make a few commentaries on the subject of alcoholic injections. The untrained physician is no more qualified to employ this nonsurgical method of treatment than he is to perform the operation. In some instances the methods employed by the uninitiated are grotesque, though fortunately harmless, the alcohol being injected directly into the tissues, or other parts in which the patient happens to complain of pain. In other cases, an injection by the inexperienced may leave the patient with a stiff jaw, facial paralysis, oculomotor palsy, or trophic keratitis. In addition to these complications, the percentage of failures with injection by the inexperienced is high. These passing commentaries are made merely to emphasize the fact that to employ the injection treatment effectively and safely requires training and experience, by which alone the necessary confidence and skill are acquired.

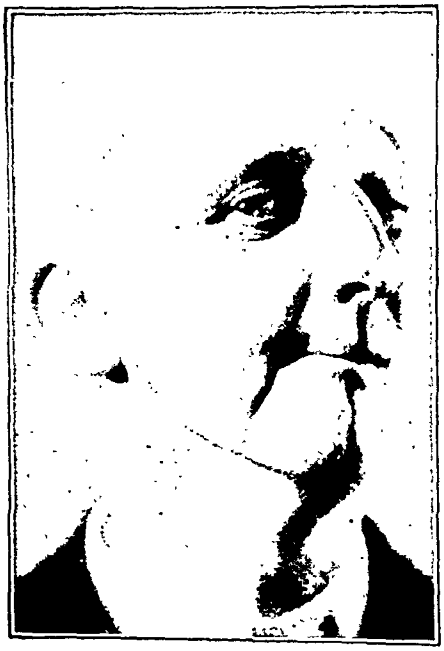

Fig. 4.—Patient with paralysis of the upper branch of the facial nerve from a faulty incision.

The methods of injection I shall not describe. Each operator will doubtless develop a technic which he varies in one way or another from time to time. I do, however, want to stress the fact that with a confidence born of experience the injection may be made painless. Frequently, and especially when the patient is unnerved from previous unhappy experiences, the operator may use nitrous oxid or very light chloroform anesthesia, and thus rob the injection of its terrors. My second commentary on the injection treatment conveys a caution as to the injection of the ganglion. The incidence of corneal complications, apart from injuries to the abducens and oculomotor nerve, is not small. Härtel himself, the originator of this method, had corneal complications in one in every four of his first twenty-four cases. This is too high a toll, and to me it makes prohibitive the treatment by injection of the ganglion, except in the few instances in which the operation may be contraindicated.

We now turn to a consideration of the radical operation. The patient should be in the hospital four or five days before the operation, both for observation and examination. Sometimes mistakes may be made in diagnosis. If the patient is suffering from a neurosis, the surgeon will regret having undertaken to relieve a pure neurosis by any surgical procedure. Many years ago, I had two unfortunate experiences, still fresh in my memory, in which the operation performed on a patient suffering from trigeminal neuralgia failed to relieve the pain. One of the cases was so evidently a neurosis that I shall mention the bare facts. Two days after the avulsion of the sensory root, the patient said she had as much pain as ever. I reopened the wound and, with the patient conscious, pulled and tugged with a hemostat on the ganglion without provoking so much as a twinge of pain. Unquestionably, at the first operation the sensory root had been divided, but in the patient's mind the pain persisted.

OPERATIVE PROCEDURE

Since 1901, in almost all my cases I have practiced avulsion of the sensory root, the operation proposed by Spiller as a substitute for gangliectomy, and described by the neurologist von Gehuchten, as the physiologic extirpation of the ganglion. Physiologically sound and technically practical, the avulsion or even the division of the sensory root is in every sense a radical cure. Ether is administered by the drop method. The anesthetization is an important feature. The patient is never deeply narcotized; once the root is divided, the use of ether is discontinued, and before the patient leaves the operating room, consciousness is practically restored.

From the first I have used the sitting posture, and believe it is of advantage for these reasons: Less ether is required, there is less venous bleeding, and the position is convenient for the operator. Without leaning or stooping over the table, he may stand erect, and as the plane of the floor of the skull is on the level with his eye, he may look directly at the structures on which he is working.

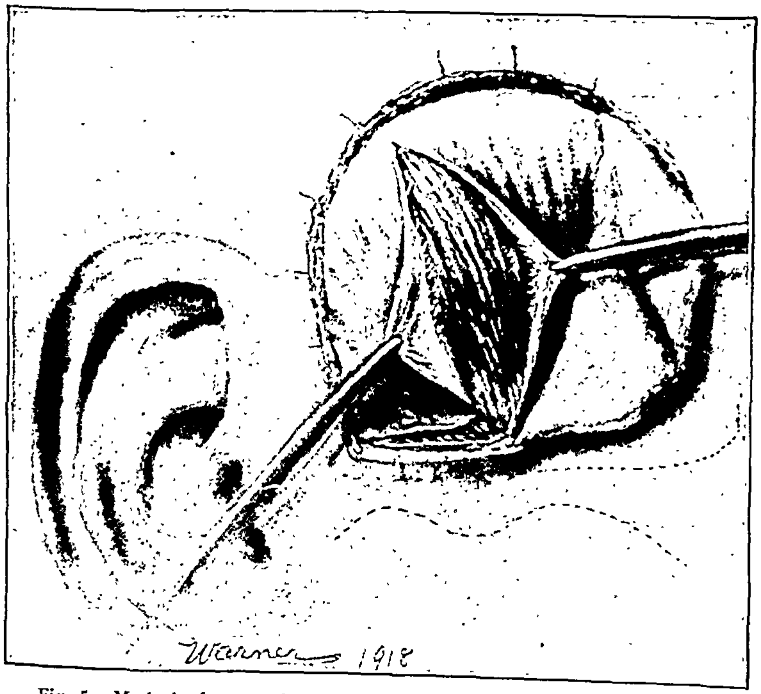

Fig. 5.—Method of approach to the ganglion; cutaneous flap reflected forward. The line of incision in the temporal fascia and muscle is projected so that this musculo-aponeurotic flap may be reflected backward.

The approach to the ganglion is a matter of the utmost importance, and many of the difficulties are obviated if the incision admits of an approach from the middle of the zygoma. From that point to the foramen ovale is the shortest route. The incision is planned with this object in mind, and, of course, must not disturb the branches of the temporal or upper division of the facial nerve. Briefly, the approach is by a flap method, with a cutaneous flap reflected forward and a fasciomuscular flap reflected backward. The margin of each flap is sutured to a towel surrounding the wound, so that no retractor and no retraction is required. These are both very practical and important details. The skull is opened with a Hudson drill, and the opening enlarged to that of a fifty-cent piece, the lower margin extending to the base of the skull. This is the end of the first stage, which we may call the approach. The field is now prepared for the second of the three stages of the operation, the intracranial maneuvers, while the third includes the closure of the wound. The dura is separated slowly from the base of the skull as well as from the temporal bone wide of the bony opening until the foramen spinosum is in sight. This is easily identified. Before the operator divides the middle meningeal artery, which passes through it, he plugs the foramen with cotton, wax or some convenient material. The next objective is the foramen ovale close by. The dural reflexion over the mandibular division, as it enters the foramen, is cut, and by blunt and sharp dissection the posterior third of the superior aspect of the ganglion is stripped of its dura propria until, at the apex of the petrous bone, one easily recognizes the sensory root. The latter should be completely isolated, the inner as well as the outer aspect, and with a special hook the root is picked up and by gentle traction severed from its central attachment. This concludes the second stage and, as the purpose of the operation is now fulfilled, there remains only the closure of the wound, requiring usually four tiers of sutures.

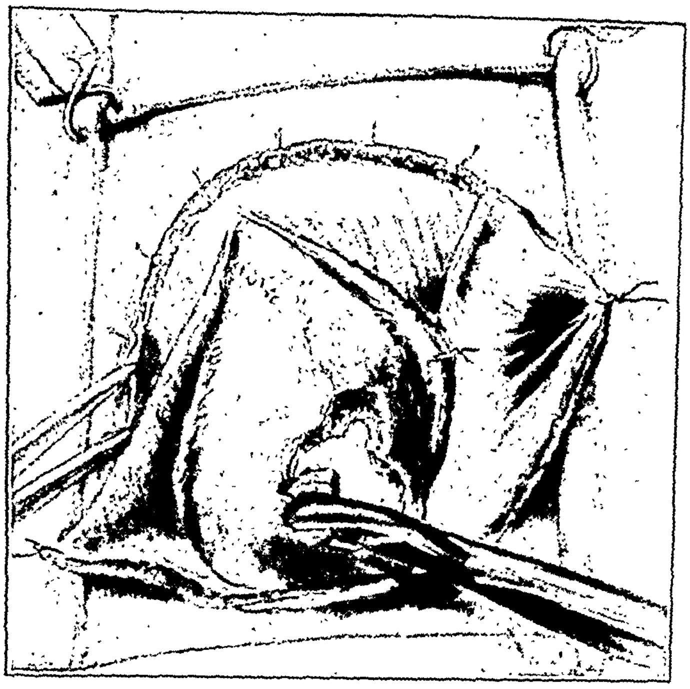

Fig. 6.—Cutaneous flap reflected forward and musculo-aponeurotic flap backward and stitched to towels; opening in skull being enlarged with rongeur forceps.

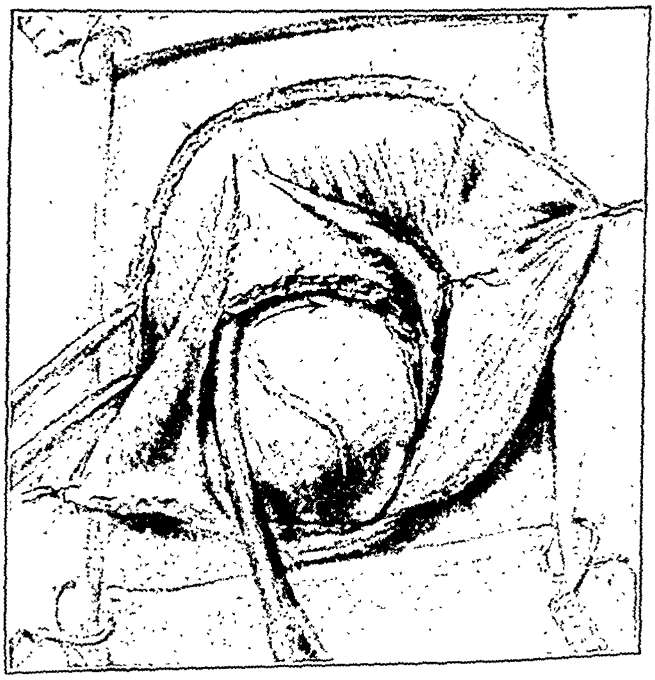

Fig. 7.—Separation of the dura as widely as possible from the margins of the bony opening.

The convalescence after the operation is surprisingly free from discomforts. In the course of a few days, as a rule, the patient leaves his bed, and by the end of the week the wound is healed, the stitches removed, and the period of surgical care and responsibility is over. To avoid corneal complications, the patient is instructed to wear goggles whenever he leaves the house, throughout a period of at least one year.

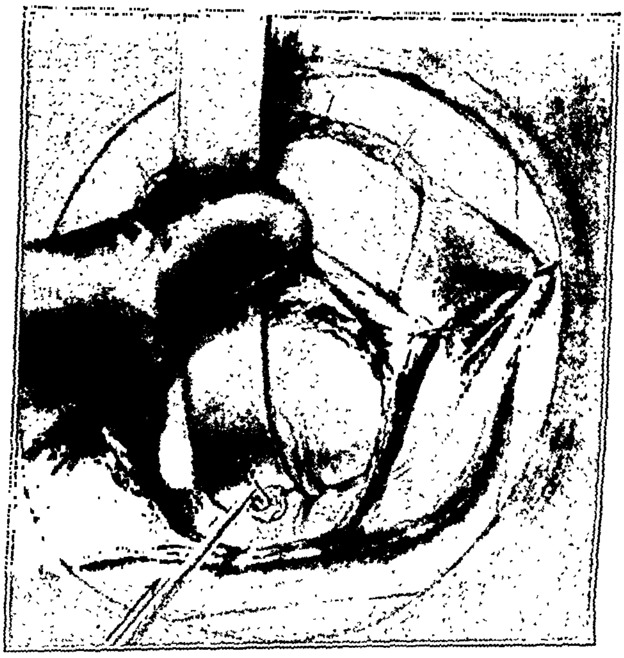

Fig. 8.—Preparation for plugging foramen spinosum with wax on end of special applicator. The foramen spinosum is readily detected by following the groove for the middle meningeal artery on the base of the skull.

The description of the operation has been necessarily brief, and many details and complications have been omitted. As a matter of fact, the operator almost unconsciously varies the technic from time to time, so that I have hesitated to lay down hard and fast rules. Needless to say, some of these operations are much more difficult than others, and considerable resourcefulness is necessary to meet obstacles as they arise. In some instances hemorrhage may be a harassing feature; in others, adhesions of the dura propria to the ganglion, probably the result of previous alcoholic injection or possibly a basilar meningitis of specific origin, may be so dense as to make the exposure of the root difficult; in an exceptional case the root may be so deeply situated that its exposure has been abandoned and the ganglion removed. The operator must always be prepared for any exigency, and to perform the operation with uniform success requires a maximum of patience and resourcefulness. The time required to expose and divide the root varies from forty-five minutes to more than two hours.

RESULTS

In considering the results, I refer only to the major operation, and will review it from various angles, first as to the permanency of relief, of which there can be no doubt, if the entire root is sectioned. The root cannot regenerate itself. My first operation was performed in 1901, and when last heard of fifteen years after the operation, the patient was free from pain. In all my 121 intracranial operations, I have been called on only once to operate a second time. In this case I found that the inner portion of the root had escaped me. This experience prompts me to warn the operator of the ease with which the inner portion of the root may remain attached to the dura and be overlooked. The fibers of the sheathless root are easily separated one from another, and its inner portion, if adherent to the dura, may be concealed behind the retractor employed to elevate the temporal lobe.

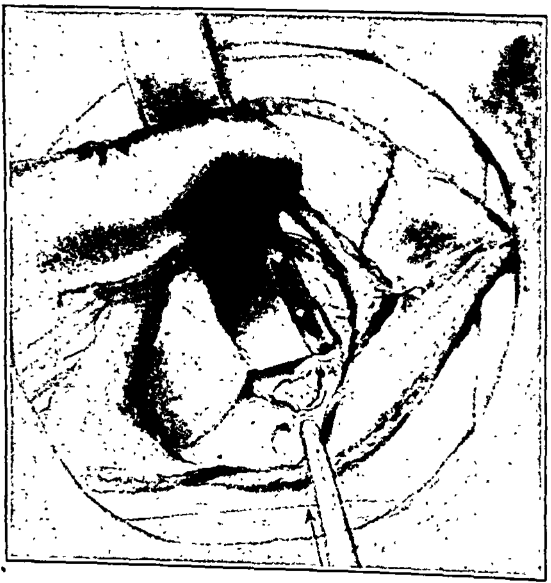

Fig. 9.—The foramen ovale and the mandibular division exposed, and the separation of the dura propria from the surface of the ganglion begun.

The second result of the operation relates to subjective disturbances. The majority of patients, grateful for the relief afforded, accept the anesthesia and numbness without complaint, soon becoming accustomed to it. To the minority, the numbness continues to be a source of annoyance for some time.

The motor disturbance, following inclusion of the motor with the sensory root, involves loss of function in the temporal, masseter and buccinator muscles. In a great many instances I have been fortunate in not being compelled to sacrifice the motor root, and in later years I find an increasing percentage of cases in which the motor root has been saved. There is more or less inconvenience when the function of the buccinator is lost, since food accumulates in the sulcus between the teeth and the cheek because of the anesthesia and the loss of power in the cheek.

These sensory and motor sequelae are of no very great moment, at least when compared with the intense suffering, for the relief of which the operation is performed. The only sequel that might be said to be of serious moment is keratitis. This lesion of trophic origin will occur once in a while. If promptly recognized and properly treated, the corneal ulcer will heal. If utterly neglected, as it was in two of my earlier patients, the eye may have to be sacrificed. In addition to these sequelae, there were four instances in which it was necessary, for periods of several months to several years, to suture the lids at the midpoint. In this type of case, the patient, even with lids sutured, can see to one side or the other, though not directly in front.

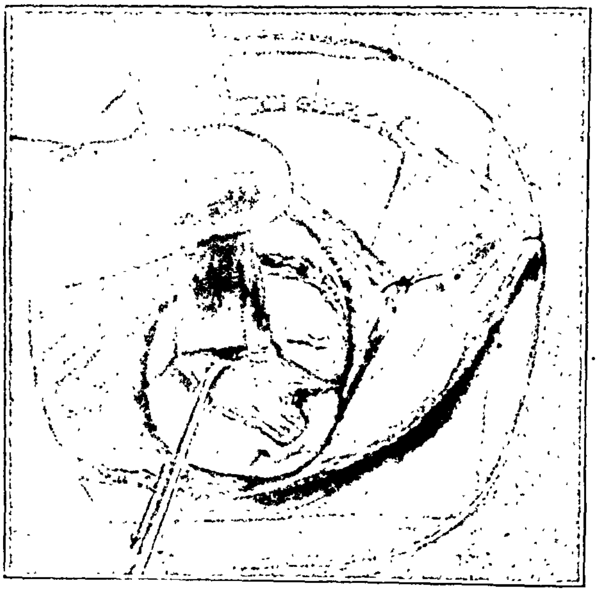

Fig. 10.—The posterior third of the ganglion has been uncovered and the sensory root isolated; it has been encircled with a small, blunt hook preliminary to avulsion.

RISKS OF THE OPERATION

In regard to the risks of the major operation, there is naturally a good deal of apprehension on the part of the patient, but usually much more on the part of the family physician. The operation, of course, has its attendant risks, which we might suppose to be proportionately greater than in other major operations on patients past middle life. The supposition, however,

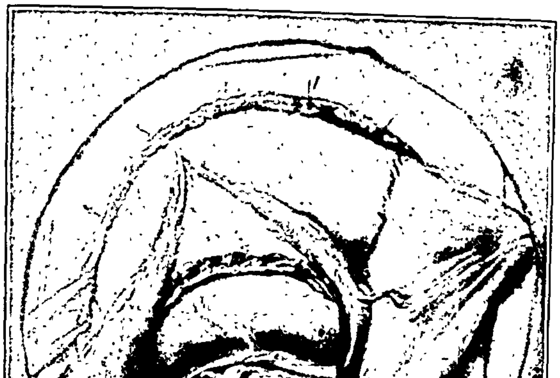

Fig. 11.—The sensory root has been avulsed and the free end is lying forward on the surface of the ganglion.

has no foundation in fact. There seems to be an extraordinary misconception on the part of the profession as to the present status of the operation on the ganglion or root. It is usually represented as a court of last resort, a sort of kill-or-cure method, as a result of which the patient, if he survives, will be paralyzed on one side of the face and will lose his eyesight. Because of the frame of mind in which the patient consults the surgeon, the former needs some reassuring. In stating the risks of the operation, I shall refer only to my own clinic. Since 1901, there have been, all told, four deaths in 160 operations. Two of these were due to apoplexy, and all of them were among subjects of the 121 intracranial operations. There was one death in 1904, and one in 1910, and ere were two in 1912. In a series of eighty-seven ısecutive operations there have been no deaths since 1912.

Over other radical operations, such as the removal of the ganglion, the Abbe operation or the Hutchinson operation, avulsion of the sensory root has so many advantages that it should be and is recognized as the operation of choice. It is easier of execution than any other, it subjects adjacent structures to no risk, and it is attended with a smaller percentage of corneal complications and with a lower mortality. On the whole, it is the most satisfactory surgical procedure with which I have had to deal.

1724 Spruce Street.

THE CAUSE OF LUMBAR PUNCTURE HEADACHE

RUSSELL G. MacROBERT, M.B. (Tor.)
Associate Physician, Neurological Institute
NEW YORK

Lumbar puncture headache differs from all others in that, being present when the patient is *sitting* up, it completely disappears when he lies down. It is throbbing and severe, and felt mostly in th occipital regions. No drugs give suffic allow its victim to walk about and attend or even to sit up. The pain comes on he sits up, being fully present in twenty takes about the same length of time to he lies down. This situation usually persists for about seven days with full severity, and then ends somewhat abruptly in the course of twenty-four hours.

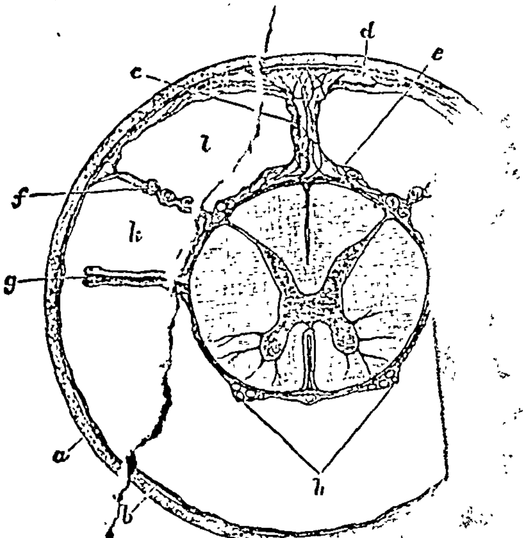

Fig. 1.—Section of the spinal cord within its arachnoidal space which contains the cerebrospir Retzius, Schäfer's Histology): *a*, dura mater; *b*, a arachnoid space.

The only effective treatment is a week's stay in bed with the head low. While in this position the patient is quite comfortable, and there are no clinical signs of trouble present.

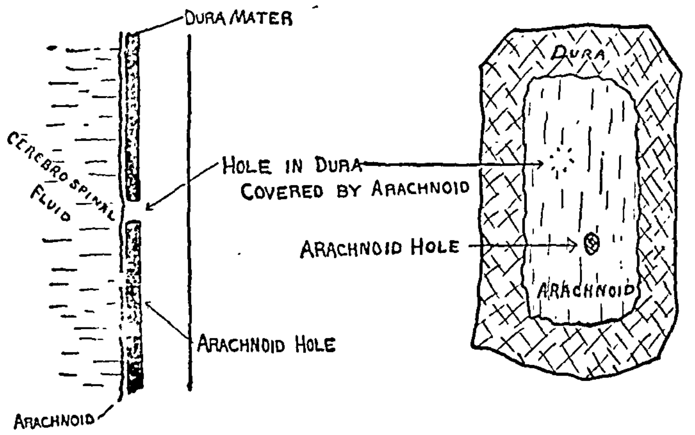

Fig. 2.—Spinal membranes with normal closure of puncture hole: no epidural leakage; no headache.

Regarding causative or influencing factors of the headache, various speculations have been made concerning the importance of such points as the ra with which the fluid is withdrawn; the position patient during the puncture; the degree of pr existing in the spinal fluid at the time of pu the disease condition of the patient, and his age these points are now generally regarded as unimpor tant.

the con- pidity of the essure

There are three other points that linger with some observers, and these have been made interesting by discussion. They are: (1) lying *flat on the back for twenty-four hours following* puncture; (2) performance of puncture when the fluid shows signs of active syphilis, and (3) the amount of fluid withdrawn.

1. It has been our custom at the Neurological Institute to ha patient lie flat on his back for twenty-four ho v ar puncture. The small amount for examination must by this ti satec 1 the chances

thirty cases
a statement

frequently heard in connection with the second point, regarding the performance of puncture when the fluid shows signs of active syphilis. This statement is to the effect that headache is unlikely to occur in these cases. In the accompanying table only eight spinal fluids may be considered as showing signs of active syphilis, and yet it was in three of these that headache occurred. If this percentage, 37.5, is compared with the 40 per cent. in the whole series, it becomes evident that we may not regard this point as an influencing factor of the headache.

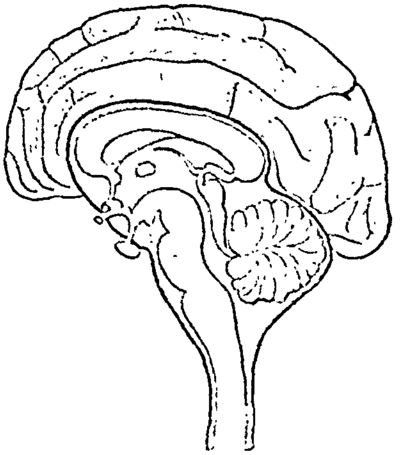

Fig. 4.—Location of the cisternae and canals of the subarachnoidal space (Poirier and Charpy, Howell's Text-Book of Physiology).

3. The third point—the amount of fluid withdrawn—is interesting. The liability for headache to occur when only 2 c.c. of fluid are withdrawn, as readily as when 20 c.c. are withdrawn, has often been demonstrated. This has led some to assume and contend that headache did not depend on loss of cerebrospinal fluid. To support their contention, they have cited the fact that headache is not a frequent complaint after spinal cord operations, although much fluid is usually lost during these operations. The fallacy of this illustration becomes apparent when we recall that after spinal cord operations, the patient is kept on his back for at least two weeks; lumbar puncture headache is not in evidence while a patient is on his back, and the situation responsible for it, whatever it is, is never present, even in the worst cases, for as long as two weeks.

Whereas we are far from having any proof that loss of fluid does not cause lumbar puncture headache, and the consensus of opinion is that in some way it must be responsible, it seems ridiculous that when probably 60 c.c. or more are secreted in a day, an alteration in the intracranial situation sufficient to produce violent headache of seven or more days' duration can be made by the removal of from 2 to 5 c.c.

After a consideration of these facts, it was evident that some new point of view must be obtained in order to solve the problem. A critical analysis of the whole puncture phenomenon brought to light a factor that seems not to have been previously considered. It occurred in answer to the question, After the puncture, is everything within as it was before, with the exception of an absence of a few cubic centimeters of spinal fluid?

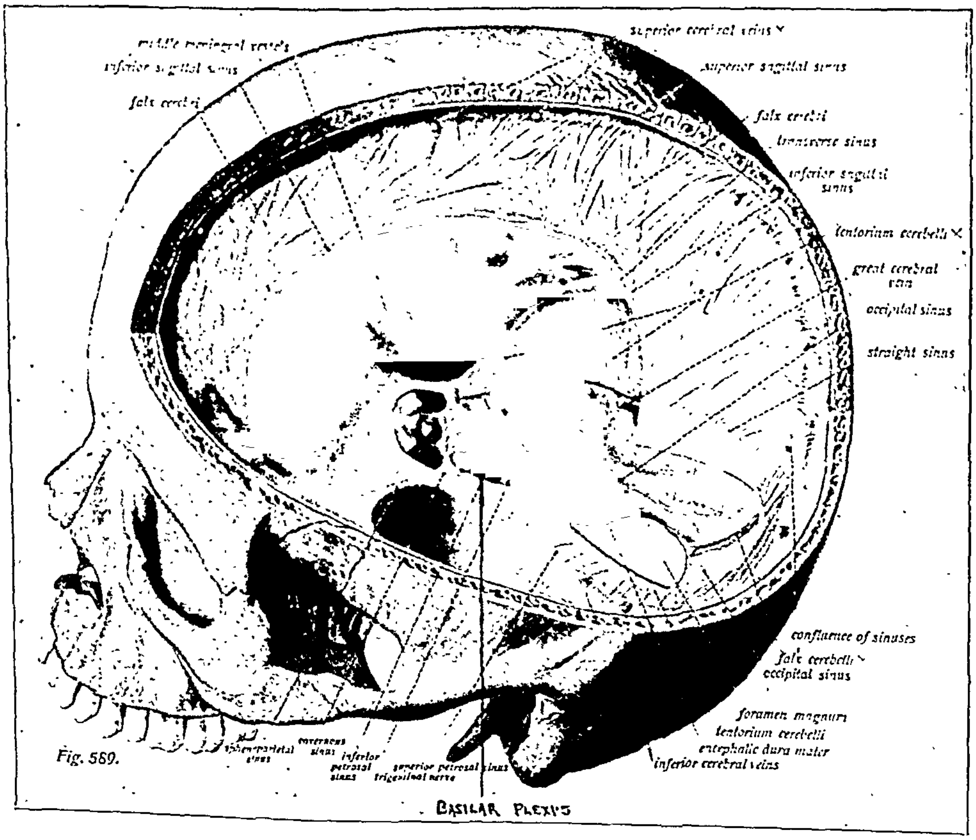

Fig. 5.—Location of basilar plexus of veins (from Sobotta-McMurrich).

To obtain fluid by puncture, the needle must pierce two membranes, the dura and the arachnoid. The dura forms a rigid, tough, fibrous sac, just within the vertebral canal. The arachnoid tissue, which is nonvascular and delicate in texture, is full and loose, and it is in close apposition to the dura. The fluid is contained in a space between the arachnoid and the pia mater, the latter membrane closely investing the spinal cord.

We are so accustomed to withdraw blood from a vein without an afterthought as to its closure that I suppose we have assumed the same mental attitude, unconsciously, after lumbar puncture. But in the latter instance we have punctured a fibrous sac distended with fluid — made a hole in a stiff membrane that has no contractile tissue.

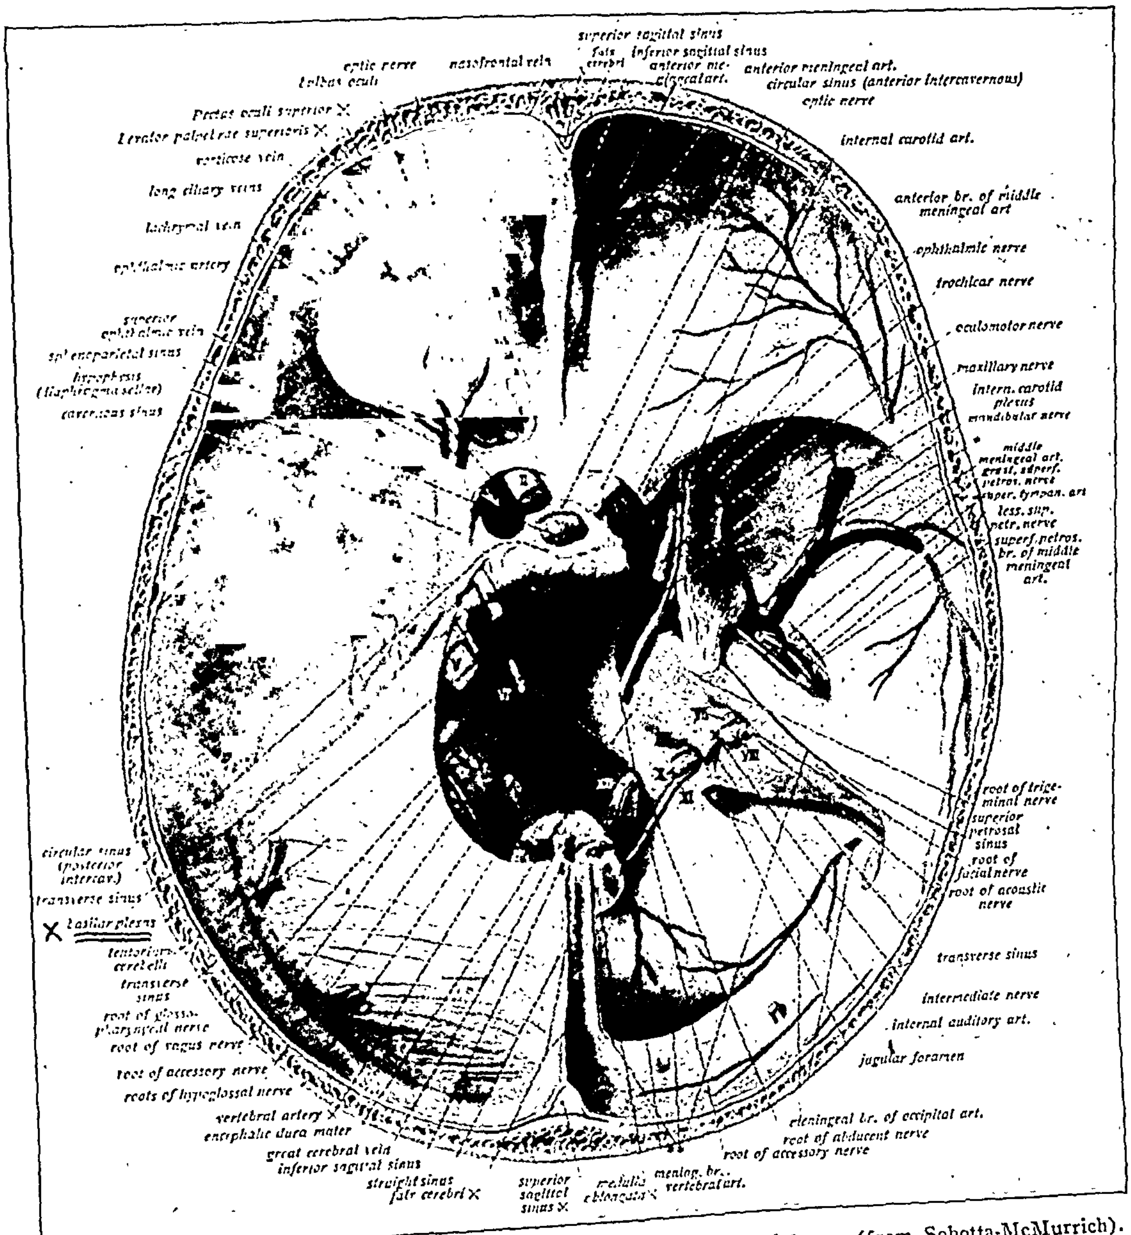

Fig. 6.—Location of basilar plexus on clivus of sphenoid and occipital bones (from Sobotta-McMurrich).

One may be startled by the fact, but can soon convince oneself by a visit to the operating or postmortem room with some needles, that a puncture in this rigid dural membrane usually persists as a clean edged, round hole. The spinal fluid is always under some pressure in its sac, so what is to prevent a continuous leakage into the epidural space in the spinal canal, following the extraction of the needle?

From a study of this point, I have become convinced that closure of the puncture hole usually takes place in the following way: The arachnoid tissue, as it drops from the point of the departing needle, is swept snugly against the dura mater, by the pressure of fluid within. In this way the dural hole is blocked by an intact area of the arachnoid membrane, as the puncture holes, being small, are unlikely to approximate.

If the puncture hole is not blocked, it is because the delicate arachnoid tissue clings around the departing needle, and its hole is pulled into and through the hole in the dura. There it impinges, and this invagination forms a spout or wick for the easy drainage of the whole cerebrospinal fluid sac, and also prevents the rapid healing, which would otherwise occur, of so small a dural opening.

All the fluid secreted by the choroidal glands during seven or eight days, the time seemingly necessary for the hole to close by tissue growth, will be lost by leakage into the epidural space, where it can be absorbed readily, because the epidural space of the spinal canal is comparatively very large, and contains only loose connective tissue, with venous plexuses and lymph channels.

It is evident, in the light of the foregoing facts, that the amount of fluid collected in the test tube will be no indication whatever of the great loss that occurs, when a puncture hole does not become properly occluded when the needle is withdrawn. An instance occurred at the Neurological Institute in January, 1918, which glaringly demonstrates the importance of this occult leakage into the epidural space, and which also indirectly led me first to consider the possibility of such a leakage, and to the explanation presented here.

A lumbar puncture that I was attempting was interrupted by the nervousness and impending syncope of the patient. I was obliged quickly to withdraw the needle, which I believed from my sense of touch to have already pierced the membranes, without collecting or even seeing any fluid. Nevertheless this patient developed a typical lumbar puncture headache which lasted with severity for eight days.

At the time, of course, this was extremely puzzling. Now it is obvious that an apparently dry tap, if the membranes are pierced, may as truly become one of continuous epidural leakage as any other puncture, and it is continuous epidural leakage of cerebrospinal fluid through a patent puncture hole that is the primary and essential causative factor of lumbar puncture headache. Let us see how this factor operates.

The cerebrospinal fluid contained in a closed sac forms a pad for the brain and spinal cord. At the base of the brain this pad becomes a veritable cushion or water-bed. When the fluid leaks away through a hole in the lower end of this sac, the base of the brain loses its supporting fluid cushion. We may expect this support to remain absent until the puncture hole heals and the fluid again fills and distends the sac sufficiently to reestablish this water-bed. The loss of this supporting basal cushion may be regarded as the secondary causative factor in the production of the headache. How does this produce pain?

A headache, which, let us recall, comes on when a patient sits up, and disappears when he lies down, must obviously be mechanically produced. Pressure of the meninges by the brain weight, against the irregular bony surface of the base of the skull, which would ensue when the patient sits up, in the absence of the basal fluid cushion, might be considered to be sufficient cause for headache. However, another explanation appeals to me as more aptly applying to the situation.

A mechanical accident following spinal puncture has caused sudden death in certain brain tumor and other intracranial conditions accompanied by increased intracranial pressure. The withdrawal of fluid deprived the base of the brain of support, and allowed such forcible descent of the pons on the clivus of the occipital bone that prolapse of the medulla through the foramen magnum occurred. In the average normal case if the supporting fluid cushion is completely lost by continuous leakage through a patent puncture hole, we may expect the pressure of the brain weight transmitted through the pons to the clivus when the patient sits up to be considerable.

The basilar plexus on the clivus of the occipital bone is formed by an extensive anastomosis of flat venous plexuses. It is connected on either side with the cavernous and inferior petrosal sinuses, and with the neighboring blood channels (Sobotta-McMurrich). The other venous channels that drain the cranial cavity at the base are rigid inelastic tubes, and they are thus safe from closure by pressure. The basilar veins differ in this matter of security from closure. They depend on the cushion of cerebrospinal fluid to keep off the pressure of the pons, which is directly above.

When the patient sits up, and the cushion of fluid is absent, the weight of a good part of the brain is suddenly imparted through the pons to this communicating plexus. The blood about to leave the skull is impeded, and forced to turn back and travel by other crowded pathways. The resulting congestion causes a sudden rise of venous pressure.

The sudden onset of severe headache when the patient sits up can now be understood as due to the sudden heightened intracranial pressure due to the rise of pressure in the cerebral veins; its entire relief, when the patient lies down, as due to the fall of pressure when the weight is removed from the veins on the clivus. In the course of a week the puncture hole heals, the fluid is rapidly made in sufficient quantity to fill and distend the entire sac, and the integrity of the brain cushion or water-bed is reestablished. The headache, which was a purely mechanical affair dependent on the loss of that cushion, is gone.

FURTHER OBSERVATION ON A TRANSPOSED METATARSAL BONE

W. L. BROWN, M.D.
AND
C. P. BROWN, M.D.
EL PASO, TEXAS

In 1916, we reported[1] an experiment (Experiment 1, Dog 7, New Series) in which the second metatarsal bone of a dog 10 weeks old was transposed into the bed left by the removal of the second metatarsal of the opposite forefoot. As we stated, three months and twenty-six days after the transposition, the bone had not only survived but had actually grown in length and circumference.

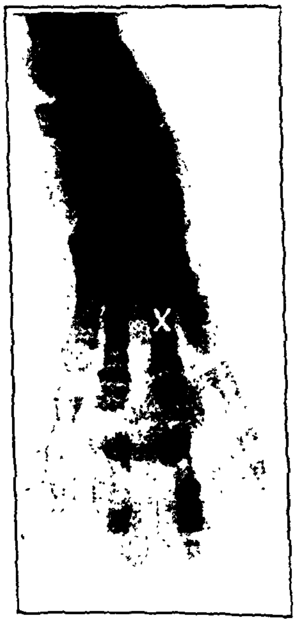

Fig. 1.—Right second metatarsal transposed in position formerly occupied by the left, immediately following operation.

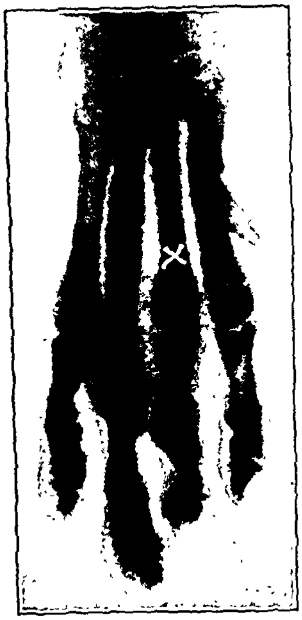

Fig. 2.—Three months and twenty-six days after transposition: Bone has not only survived and performed its function, but has actually grown as have the other bones of the foot.

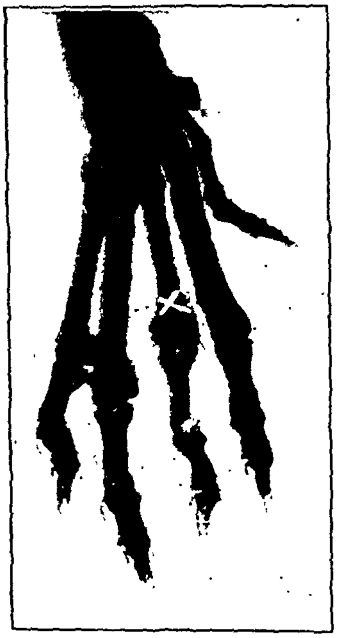

Fig. 3.—Two years after the operation the bone has survived and performed its function, but its growth as shown in *Figure 2 did not* continue as long as that of the other bones.

A roentgenogram taken recently reveals that the growth of the transplanted bone has not kept pace with the other bones of the foot either in length or circumference, though it has lived and performed its function for two years.

Conclusions have often been drawn from experiments of short duration, when a more prolonged observation would show that there was a handicap because of the transposition that could not be completely overcome. If this experiment had been done on a dog that remained small, or one already fully grown, the point brought out above would have been missed.

OPERATIVE TREATMENT IN SELECTED CASES OF CHRONIC PERIPHERAL FACIAL PARALYSIS *

WILLIAM SHARPE, M.D.
Professor of Neurological Surgery, New York Polyclinic Medical School and Hospital
NEW YORK

Not only is the condition of facial paralysis, especially of the peripheral type, a most noticeable deformity, but the resulting contractures in chronic cases frequently impair the speech, mastication and deglutition; inability to close the homolateral eye permits a chronic conjunctivitis to result, and if palpebral contractures occur, then an eversion of the eyelids is a common sequela. In addition to these definite objective impairments resulting from persistent facial paralysis, it should be remembered that the subjective reaction of such a deformity on the patient is very marked—so much so that few patients having a complete facial paralysis persisting over a period of two years and longer show a normal reaction emotionally. They are easily depressed, and they limit their lives more and more to one of seclusion; particularly is this true of women.

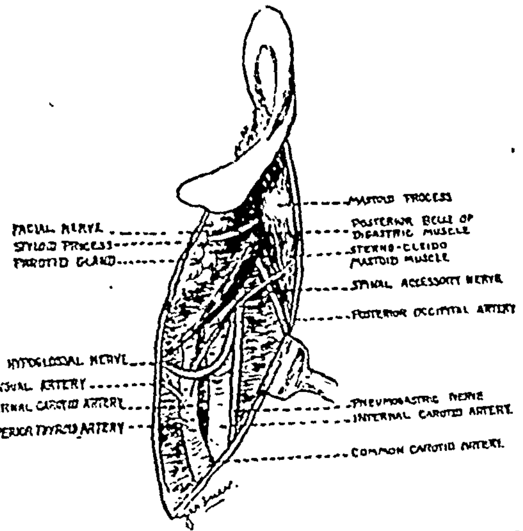

Fig. 1.—Anatomic relation of operative area (schematic), showing the accessibility of the spinal accessory and hypoglossal nerves for the facial anastomosis.

Facial paralysis may be considered of the peripheral type when the lesion exists at the facial nucleus in the pons or at any point along the course of the facial nerve from this nucleus down to its bifurcation into the facial branches within the posterior border of the parotid gland; naturally, a lesion of one of these facial branches distal to this main division would produce a paralysis of the muscles supplied by the individual branch affected, and I shall not consider in this paper the treatment of these individual branch lesions, as it is the same as the treatment of any peripheral nerve injury.

Lesions of the facial or seventh cranial nerve producing a peripheral facial paralysis occur more frequently than in any other single nerve; the paralysis results in almost three fourths of the patients from a so-called "chill" of the facial nerve; in fact, very little is known as to the real cause of this more common form of peripheral facial paralysis, or Bell's palsy—whether it is an infective process or a simple nerve degeneration or their combination.

The next most common cause of peripheral facial paralysis is otitic disease. Any suppurative process of the middle ear with or without a definite involvement of the mastoid cells may produce an ipsolateral facial paralysis either by direct extension and compression of the facial nerve or by the resulting edematous swelling of the nerve itself within a narrow aqueduct of Fallopius. In this connection I should like to mention the infrequency at present of peripheral facial paralysis following mastoid operations. It still occurs, but the paralysis is rarely a permanent one, since it is due more to an operative edema of the facial nerve than to its complete severance and destruction—a fairly common operative complication as recent as fifteen years ago. This advance is undoubtedly due not only to an improved technic and greater operative care and respect for the facial nerve in mastoid operations, but chiefly to the recognition by the medical profession (and also by the laity) that the operation for mastoid disease is one for a specialist and not the general surgeon.

Another frequent cause of peripheral facial paralysis is fracture of the base of the skull; in these patients, the fracture has extended into the petrous bone either at the internal auditory meatus or more frequently through the aqueduct of Fallopius. The paralysis, however, may be only a temporary one in many cases, due possibly to merely an edema of the facial nerve rather than an actual tear or severe bony compression of it; naturally, in the latter cases the paralysis is a permanent one. During the past five years in a series of almost 500 acute brain injuries[1] with or without a demonstrated fracture of the skull, I have observed a complete *peripheral* facial paralysis in but nine patients, and in only three of these patients was the paralysis a complete and permanent one.

A much less frequent cause of peripheral facial paralysis is to be found in tumors gradually compressing the facial nerve itself (and thus producing a facial paralysis of slow onset), particularly in those portions between the facial nucleus in the pons and the internal auditory meatus. Then again, after the nerve has emerged from the stylomastoid foramen to the point of bifurcation in the posterior portion of the parotid gland; the latter tumors are usually palpable, and thus an early removal by careful dissection of the benign tumors makes a permanent relief possible.

There are numerous other causes of peripheral facial paralysis of the infective and toxic types: basilar meningitis and occasionally syphilis; traumatism during difficult labors and also a bilateral paralysis may occur following many causes; besides, the various war wounds and gunshot injuries are becoming a very common cause of facial paralysis. I shall consider in this paper, however, only the operative treatment in selected cases of chronic peripheral facial paralysis that have persisted over a period of one year in spite of all expectant medical treatment, such as massage, electricity, external heat, and medicine. If, after such a period of one year of intensive rational treatment of a patient having the condition of complete peripheral facial paralysis due to a so-called "chill" or Bell's palsy, otitic complications, fractures of the skull and certain other causes, the paralysis remains practically a complete one for at least the preceding six months, then I feel that such a patient should be given the opportunity of obtaining a definite improvement by an operative procedure of facial nerve anastomosis.

---

* On accou of its length, this paper could not be published in full e JOURNAL, reprints of the complete paper, however, will be mailed author on request.

detailed report of the operative patients will be made in a later Their improvement has been both rapid and marked, and it is hat this is due chiefly to the method of operation described per, which is merely a preliminary report.

[1] Sharpe, William: Observations in the Diagnosis and Treatment of Brain Injuries in Adults, THE JOURNAL A. M. A., May 13, 1916, pp. 1536-1540.

If it is possible (and it rarely is) to decide immediately and without a question of a doubt that the facial nerve has been irreparably damaged, either through being completely severed or permanently impaired by bony compression or an infective process, then undoubtedly the ideal time for the operation would be just as early as the complete permanent damage to the facial nerve could be ascertained. Not only would a perfect nerve anastomosis occur much more easily, but the muscular atrophy and contractures would thereby be avoided; at times, this early operation is possible following a severance of the facial nerve during a mastoid operation or an operation on the neck injuring the facial nerve peripherally to its emergence at the stylomastoid foramen.

There have been several operations devised to improve the condition of complete and persistent peripheral facial paralysis. The object of each of these operations has been to restore volitional and emotional control to the paralyzed facial muscles by making possible the transmission of efferent motor impulses from the central portion of an adjacent motor nerve to the peripheral impaired portion of the facial nerve. That is, in order to "bridge" and thus circumvent the obstructive lesion of the facial nerve, which cannot itself be treated locally by any means now known, and thus eliminate functionally that impaired portion of the nerve, it is the purpose of the operation to connect the cerebral motor cortex, contiguous with the cerebral motor cortex of the facial nerve, to the peripheral portion of the facial nerve itself by means of a peripheral nerve anastomosis. Anatomically, there are only two motor nerves, adjacent to the facial nerve after its emergence from the stylomastoid foramen, that can be used for this anastomosis; these nerves are the spinal accessory and the hypoglossal, as is clearly shown in Figure 1 their close relationship with the facial nerve makes the various modifications of peripheral nerve anastomosis a practical and a comparatively easy one. The glossopharyngeal nerve is too deeply situated and therefore technically inaccessible for the facial anastomosis.

Fig. 2.—Schematic representation of author's hypoglossal and facial nerve anastomosis for complete chronic peripheral facial paralysis; *A*, enlarged view of anastomosis of central half of hypoglossal nerve to peripheral cut end of entire facial nerve; *B*, enlarged view of nerve fiber suture of hypoglossal nerve itself.

During the past fifteen years a number of these facial anastomoses and their modifications have been described; those by Ballance, Frazier and Taylor may be mentioned. The results have been encouraging, and yet there has not been a single patient reported in whom the end-result has been a complete return of both volitional and emotional control of the formerly paralyzed facial muscles. In some cases, I feel that this has been due to the operative method of anastomosis, and it is my purpose herein to advocate a certain method of anastomosis in the belief that it may offer a greater ultimate improvement than can be obtained by the operations that have been used.

In order to obtain all of the advantages of an end-to-end anastomosis and at the same time to avoid as much as possible the impairment of paralysis, etc., following the sectioning of an entire spinal accessory or hypoglossal nerve, the method of anastomosis described below has been performed on seven patients with most encouraging results; a period, however, of at least five years after the operation should elapse before a definite opinion of the results can accurately be obtained. From the literature, it would seem that each method of anastomosis produces a definite improvement of the facial paralysis, and yet there has been no case reported in which the improvement has been all that could be desired; it is to be hoped, therefore, that a method may be devised that will produce the greatest ultimate improvement, if not a complete cure.

In the operation to be described, only one half of the hypoglossal nerve is anastomosed to the entire peripheral cut end of the facial nerve; in this manner, not only is the easier and more rapid nerve regeneration of an end-to-end anastomosis obtained, but the hypoglossal nerve remains in continuity and regains its complete function within a period of two months. The latter is made possible by cutting several of the intact nerve fibers of the remaining half of the hypoglossal nerve and approximating them by a single suture to the peripheral cut portion of the hypoglossal nerve (Fig. 2 *B*). Thus it is possible to use for the end-to-end anastomosis more than one third of the hypoglossal nerve, and yet only a temporary weakness of one half of the tongue occurs, and no atrophy of its muscles results. I feel, therefore, that this is a distinct advance over the methods formerly used in that all of the advantages of an end-to-end anastomosis are obtained and yet none of the permanent disadvantages of hypoglossal impairment.

TECHNIC OF OPERATION

The operation itself is not a difficult one technically. By means of a small curved incision just posterior to the angle of the lower jaw, and anterior to the mastoid process (the ear lobe being held forward), the facial nerve is exposed as it crosses the styloid process externally; the nerve itself is now severed as close to the stylomastoid foramen as is possible so that a peripheral portion of at least one-half inch is obtained for anastomosis. The facial nerve should always be exposed first, as it has been reported absent or rather, "not found" in several patients so that an anastomosis was naturally not possible; it is wise, therefore, to expose it before dissecting and sectioning the hypoglossal nerve. Possibly the best landmark to use in finding the hypoglossal nerve is to expose the external carotid artery; just below its occipital branch, the hypoglossal nerve curves forward and to the outer side of the main trunk of the external carotid artery to lie between the posterior belly of the digastric muscle externally and the hyoglossus muscle internally. By blunt dissection, the hypoglossal nerve can be easily exposed forward so that a portion of at least 1 inch, and still better, 1½ inches, is obtained for the anastomosis with the facial nerve. The entire hypoglossal rve, within its sheath, and being held by its sheath, s now incised longitudinally in its midline by a small, thin-bladed scalpel, and its nerve fibers are now separated in the midline longitudinally for a distance of 1 inch at least; at the distal part of the bisection, the outer half is now severed and its central cut end is brought backward and upward to be sutured, sheath to sheath as much as possible, to the entire peripheral cut end of the facial nerve; small black silk sutures (waxed) on French needles are very satisfactory (Fig. 2 *A*).

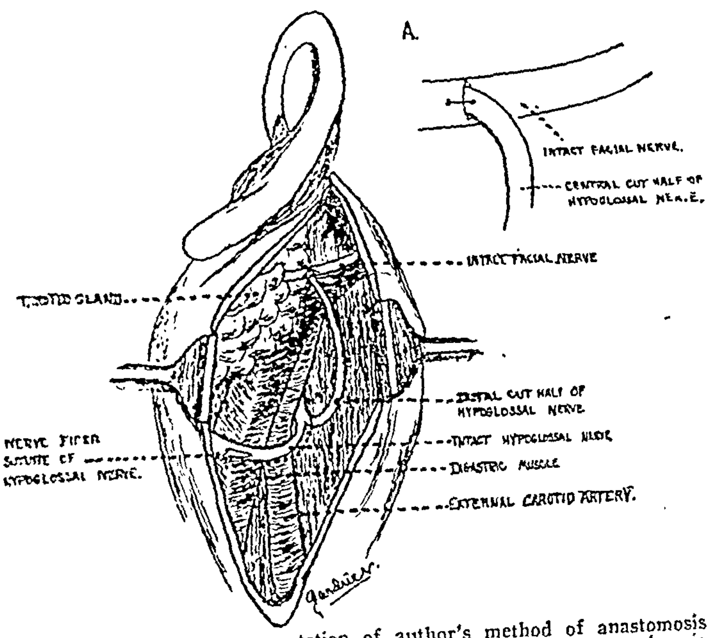

Fig. 3.—Schematic representation of author's method of anastomosis of half of hypoglossal nerve to intact facial nerve for incomplete chronic peripheral facial paralysis: *A*, right angled slit for insertion of central cut half of hypoglossal nerve into intact facial nerve.

A rather interesting observation has been made in several of the patients on whom the operation had been performed. In six patients, when the impaired facial nerve was divided at the stylomastoid foramen, the facial muscles supplied by it twitched from the mere mechanical stimulation to its distal end, and this could be repeated by merely pinching the distal end of the nerve even in those patients in whom a faradic current on the skin failed to elicit a motor response. In four of these patients, however, a faradic current applied directly to the distal cut end of the nerve also caused a mild muscular twitch, though not as strong as when the distal cut end was pinched; that is, it would seem, in these patients, at least, that a mechanical stimulus was more powerful than the electrical stimulus. Also, although a reaction of degeneration had been obtained in each of these patients, it is possible that there had been some nerve regeneration distal to the lesion; these findings, therefore, would tend to confirm the original observations of Ballance and Stewart regarding nerve regeneration in the distal portion of an impaired nerve. In only two patients, however, did the motor power return before the faradic excitability appeared. The fact, also, that in these patients, immediately after operation, the flaccid paralysis of the facial muscles was temporarily even more flaccid, and if contractures were present then these contractures were lessened and the flaccidity increased, also tends to confirm the belief that peripheral nerves regenerate not merely by means of a central to peripheral growth, but also by a peripheral repair itself independent of the central outgrowth.

In order, however, for the distal portion of the nerve to fulfil its complete function, it must be joined to the central portion of the nerve to make possible the central outgrowth and thus complete the entire nerve regeneration and function.

No fat, muscle, blood vessels, Cargyle membrane or foreign material is placed about the anastomosis in the belief that adhesions and fibrous tissues will thus be avoided. If care is used to avoid the soiling with blood of the tissues and the nerve ends themselves so that the operative field is a "dry" one, there is no need of wrapping the nerve ends with various tissues to prevent the formation of adhesions and fibrous tissues. As in all nerve work, if there is little or very gentle handling of the nerves themselves and the adjacent tissues, and, very important, a most careful hemostasis, then there will be little danger of adhesions and fibrous tissue forming. In operations on the brachial plexus in children having a paralysis of the arm following an injury to these nerves at birth (the typical condition of brachial birth palsy),[2] it has been demonstrated that there is no need to surround the nerve anastomosis with various tissue and membranes; I believe in many instances that such inserted tissues merely add to the amount of fibrous tissue to be formed; particularly is this true when fat, muscles and blood vessels are used to surround the anastomosis. A possible fibrous "choking" of the nerves by these tissues themselves must also be feared.

After the facial anastomosis has been completed, the small scalpel is again used to separate longitudinally and to cut several nerve fibers of the remaining half of the hypoglossal nerve in the same plane of the former incision (Fig. 2 *B*). The central cut end of these fibers is now approximated to the peripheral cut portion of the outer half of the hypoglossal nerve by a single suture through their sheaths; in this manner. the impairment of the hypoglossal nerve is only a temporary one, the weakness of one half of the tongue persisting not longer than eight weeks, and in two of my patients only for two weeks. It would seem, therefore, theoretically and in this one nerve at least, that the immediate anastomosis of the cut ends of the same nerve, even if a part of that nerve has been removed, occurs very quickly and the entire function is easily regained; especially is this so if several of the more medullary fibers are sutured to the more peripheral ones. Naturally, just as with the facial anastomosis, no body or animal tissues are wrapped about this nerve suture. The operative area is now gently washed with warm physiologic sodium chlorid solution so that if a small amount of blood has soiled the adjacent tissues it will be removed. The wound itself is not sutured until all oozing of blood has ceased after the retractors have been removed; warm saline compresses usually suffice. Several sutures are used to close the incision, but not tightly, so that if any oozing of blood occurs while the patient is recovering from the effects of the anesthesia, then it can escape from the operative area and thus lessen the danger of the formation of adhesions and fibrous tissue.

---

[2] Sharpe, William: The Operative Treatment of Brachial Plexus Paralysis, THE JOURNAL A. M. A., March 18, 1916, pp. 876-881.

The postoperative care is practically the same as with other operations on the neck. As soon as the incision has healed—a period of from ten days to two weeks after the operation—external heat should be applied to the impaired facial muscles, and galvanism and gentle massage used, in fact, treatment similar to that given before the operation, so that within a month after the anastomosis the same treatment as before the operation should be possible. It is interesting and instructive to observe, after the first week following the operation, an almost daily improvement in the use of the tongue. As the motor power begins to return to the paralyzed facial muscles (usually within four months), galvanism should be replaced by faradism in the treatment.

A modification of this operation might be used in selected patients having only *partial* peripheral facial paralysis, in whom the reaction of degeneration is not present and yet the paralysis is of such a character, owing to the deformity, contractures, conjunctivitis and other complications, that an attempt might be advisable to improve the condition by an operation. In these patients, after the facial nerve is exposed but *not cut*, the central cut portion of one half of the hypoglossal nerve (just as in the preceding operation) could be inserted into the *intact* facial nerve through a small *right-angled* slit of its sheath and adjacent nerve fibers—an incision just large enough to admit the central cut end of the hypoglossal nerve by means of a single black silk suture (Fig. 3 *A*). The operation would be a simple one technically, and no damage to either the hypoglossal or facial nerve would result. A right-angled cut is made in order to sever completely several of the nerve fibers of the facial nerve and thus facilitate and insure a more possible anastomosis with the fibers of the hypoglossal nerve; the mere insertion of the end of a nerve (in this case, the hypoglossal nerve) into a small *longitudinal* slit of another nerve (in this case, the facial nerve) without cutting any of the fibers of the latter nerve does not seem to be a practical method of anastomosis; just why uncut and intact nerve fiber bundles (if only a small longitudinal slit into the facial nerve is made) should be stimulated to grow beyond their intact sheaths into the cut ends of the fibers of the hypoglossal nerve does not seem logical or even theoretical, and yet a definite improvement has been reported following this method of anastomosis. For these reasons, a right-angled slit is made so that several fibers, at least, of the facial nerve will be completely severed and thus their union with the sectioned fibers of the hypoglossal nerve will be made more possible and more complete. Even if no marked improvement of the facial paralysis results from this procedure, at least no harm has been done: from the reported cases of similar grafting of other nerves, however, a definite improvement has been obtained. It would seem wiser, therefore, in the selected patients of only partial facial paralysis to attempt this method of anastomosis first, and then if no marked improvement follows within a year, the former method of facial hypoglossal anastomosis might be considered.

On account of the world war during the past three years, the number of traumatic cases of peripheral facial paralysis has greatly increased. Fortunately, however, in the majority of these facial paralyses the nerve lesion is external to the stylomastoid foramen, so that a close anastomosis of the cut ends of the facial nerve is possible in many of the patients following stab wounds and similar injuries; and, if the ends of the divided facial nerve cannot be approximated more closely than one-half inch, as in shrapnel and gunshot wounds, an anastomosis of these ends is still possible by merely connecting them by two, or better, three black silk sutures; it is then possible for the central end of the facial nerve to grow along the sutures and thus effect a union with the peripheral cut end. I have one patient in whom this occurred after nineteen months had elapsed following the operation. Naturally, all fibrous tissue about the nerve ends must be removed, and the ends themselves peeled back until normal nerve bundles are distinctly visible—otherwise no anastomosis would be possible; as in all nerve work, a most rigid hemostasis is essential. Those other patients having a peripheral facial nerve lesion in the petrous portion of the temporal bone due to a fracture of the skull, gunshot injury and similar wounds should be treated according to the permanence of the facial impairment; if it can be definitely established that the nerve is completely severed or irreparably damaged, then an early facial-hypoglossal anastomosis is advisable. But no patient should be operated on, no matter how complete the facial paralysis, unless it is definitely ascertained that the facial nerve is permanently injured, or a period of intensive treatment of at least one year following the injury has elapsed without a definite improvement of the condition.

20 West Fiftieth Street.

A COMPARISON BETWEEN CLINICAL AND ROENTGEN FINDINGS IN DISEASES OF THE CHEST

HENRY DWIGHT CHAPIN, M.D.
NEW YORK

The difficulties of interpreting physical signs in the chests of infants and little children are sometimes very great. As the questions of diagnosis, prognosis and treatment are all involved, any methods of throwing light on doubtful problems should be carefully studied. Investigations made by various observers on the interpretation of roentgenograms of the chest contents have already given promising results. The present study is in the same line of inquiry, namely, how much or how little can be learned from roentgenograms, and how the latter can fortify or throw doubt on the diagnosis made from physical examinations.

THE HEART

In the growing child, the heart not infrequently affords ground for much difference of opinion in diagnosis and consequently in treatment. The muscle is soft and subject to dilatation in disease or even from overexertion. The adventitious sounds are various and not always easy to interpret. A study of the shadow formed by the contour of the heart may help to decide whether murmurs are hemic, muscular or valvular. It is often hard to interpret properly the heart shadow in little children owing to the difficulty of keeping them quiet during exposure. A twisting of the body may cause such a rotation of the chest as to exaggerate a heart shadow in any direction. Before reaching conclusions, one must thus study the anatomic points to be sure that the chest was kept straight during exposure.

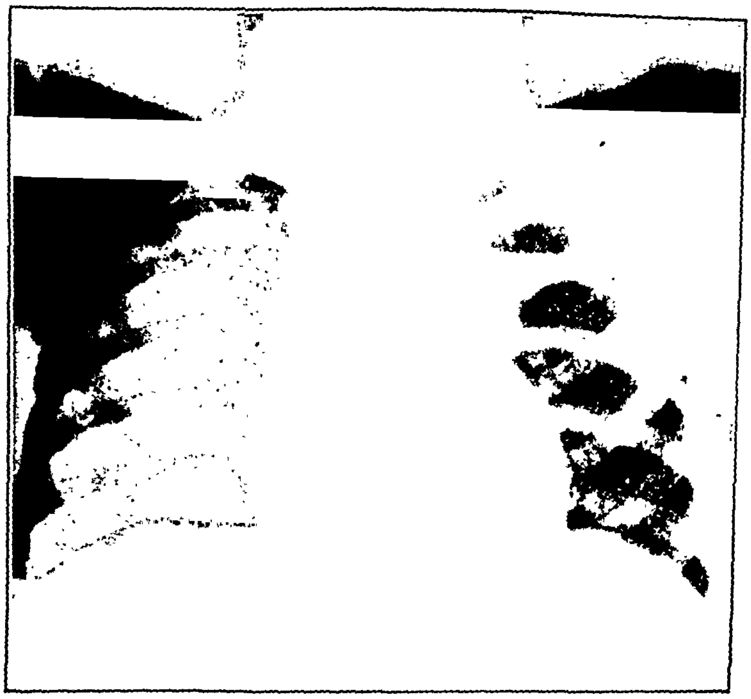

Fig. 1 (Case 1).—Normal heart; slight infiltration of hilum.

A comparison was made in fifteen cardiac cases between the roentgen-ray findings and the results of physical examinations. Seven of the cases showed practical agreement, one partly agreed, and seven failed to correspond in the conclusions reached by these two methods of examination. The following will serve as types of the comparisons:

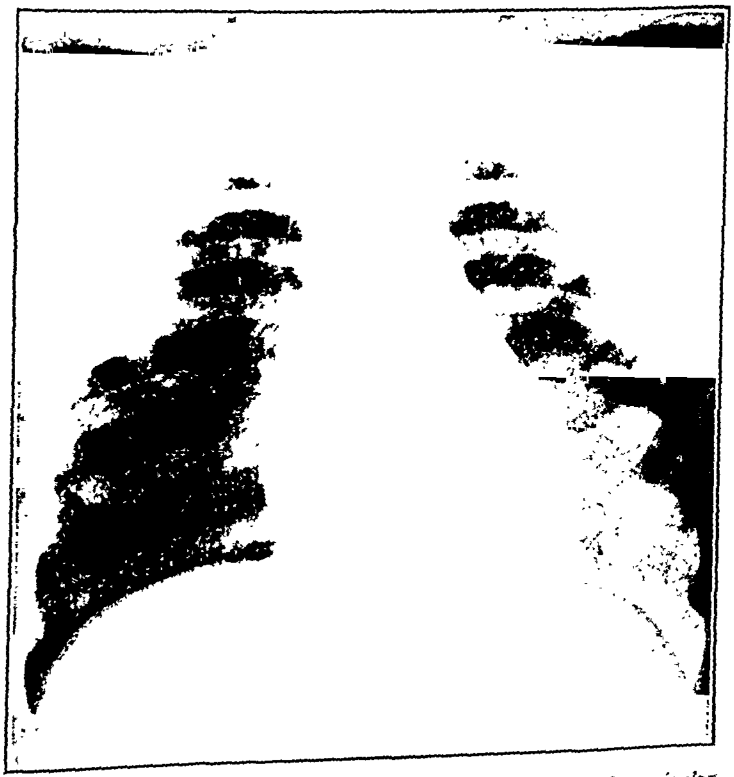

Fig. 2 (Case 2).—Heart spherical, with accentuation of left auricular and pulmonic curves and aortic recession, pointing to an early mitral lesion.

Case 1.—J. L., a boy, aged 5 years, with osteomyelitis, was found both by physical and roentgen examination to have a normal heart. The left auricular and pulmonic curves were shown to be placed well within a line drawn from the most prominent part of the aortic arch to the outer curve of the left ventricle. The roentgenogram revealed also a slight hilum infiltration.

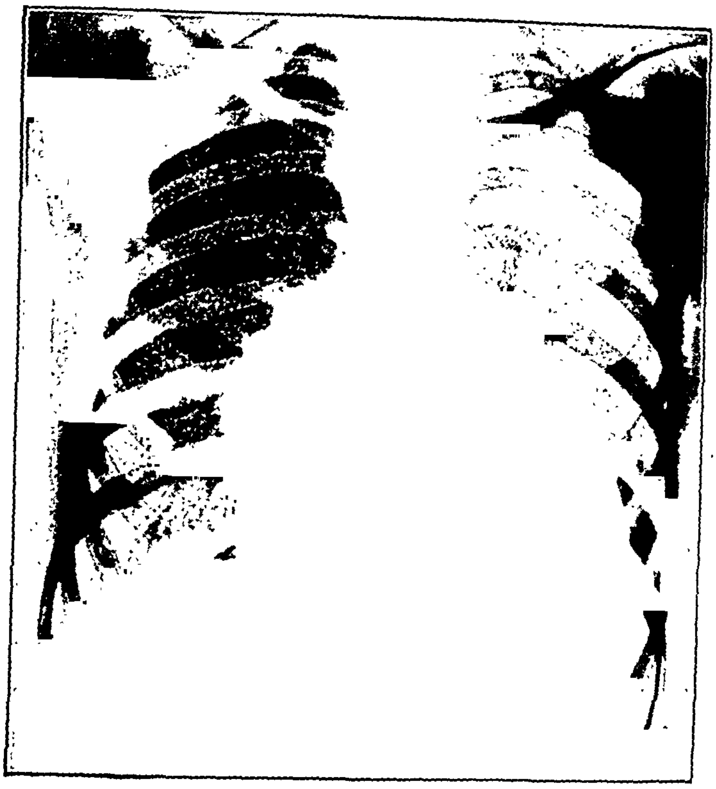

Fig. 3 (Case 3).—Marked enlargement, exemplifying the severest type of mitral disease.

The interpreter of the roentgenogram of the heart considers that an early mitral lesion causes an accentuation of the normal left auricular and pulmonic curves, producing a spherical or rounded appearance.

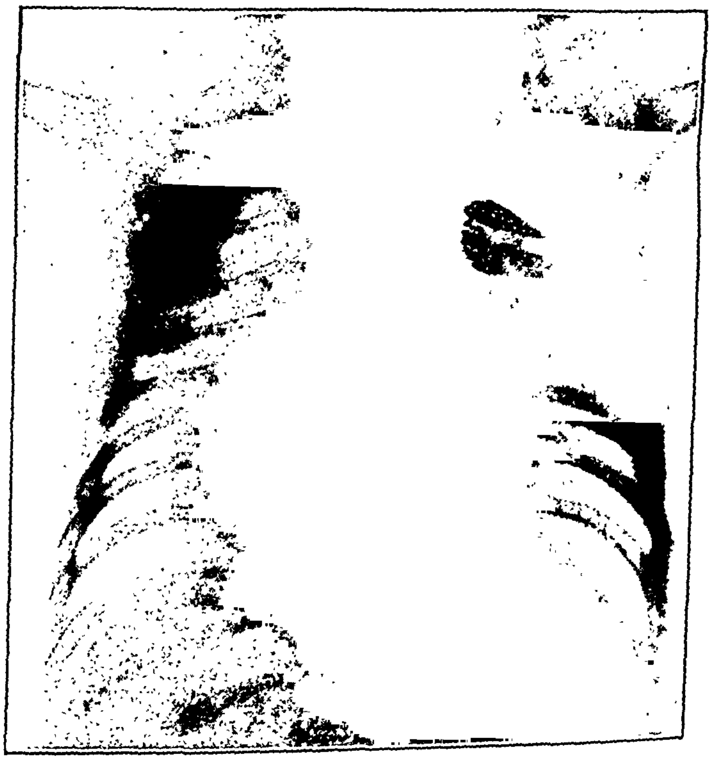

Fig. 4 (Case 4).—Increase of heart shadow to right; enlargement of right auricle, suggesting a patent foramen ovale; enlarged thymus.

Case 2.—L. S., a boy, aged 9 years, had had rheumatic pains for the past six months. The teeth were bad, but the tonsils were not diseased. Several clinical examinations by three observers on different days showed a difference of opinion as to the condition of the heart. One found a roughened presystolic sound, another reported a functional murmur, and a third considered the heart to be normal. An electrocardiogram revealed nothing abnormal. The roentgenogram, however, gave the heart a spherical appearance with accentuation of the left auricular and pulmonic curves and aortic recession, pointing to an early mitral lesion.

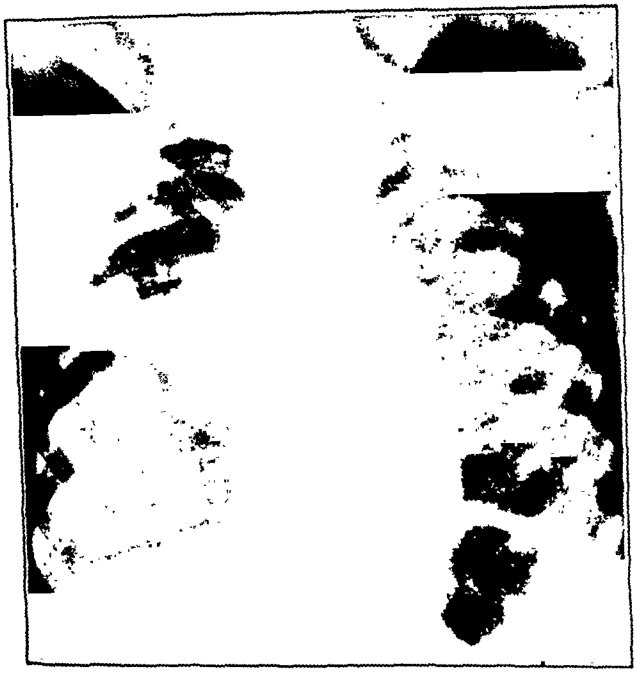

Fig. 5 (Case 5).—Increased intensity and irregularity in outline in the hilum, especially on the right side; enlarged nodes and calcific deposits in the hilum.

CASE 3.—E. W., aged 13 years, who had mitral insufficiency with hypertrophy, showed a very marked enlargement on the roentgenogram, the shadow exemplifying the severest type of mitral disease. There was a bulging out of the auricular and pulmonic curves.

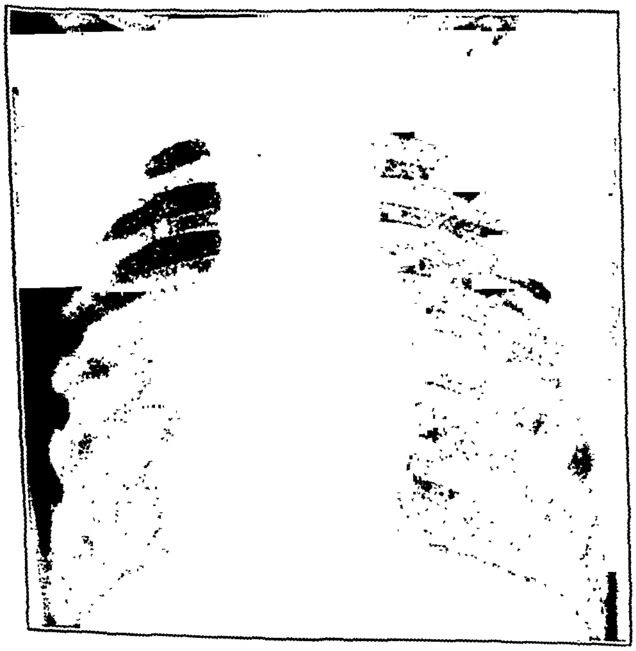

Fig. 6 (Case 6).—Marked infiltration of the hilum on both sides, with enlarged nodes and calcific deposits.

The following case was considered congenital:

CASE 4.—I. G., aged 3 months, a Mongolian idiot, was not cyanotic. There had been a cough for eight weeks. The heart was [illegible] to the right. There was a systolic murmur over the base. There was dulness over the upper part of the sternum. The roentgen ray revealed the heart shadow increased to the right and enlargement of the right auricle [illegible] a patent foramen ovale. The thymus was enlarged.

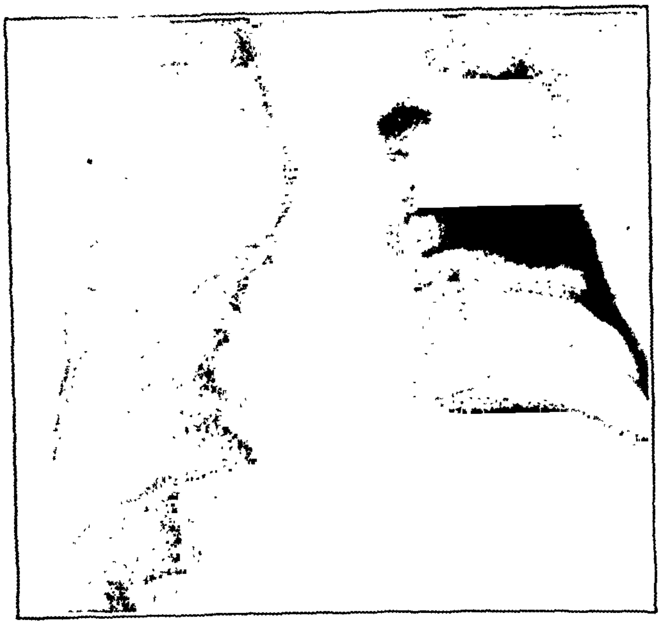

Fig. 7 (Case 7).—Partial consolidation of right upper lobe.

HILUM, LUNGS AND PLEURA

From the point of view of the lungs, the combined study of the physical signs and roentgenograms was made in ninety-seven cases, with a substantial agreement in seventy-seven and a disagreement in twenty of the cases. As examples of the latter, five gave roentgenographic evidence of lobar pneumonias that were not detected by physical signs, two gave physical signs of lobar pneumonia that were not confirmed by the roentgen ray, three showed physical signs of bronchopneumonia not exhibited by the roentgen ray, and two

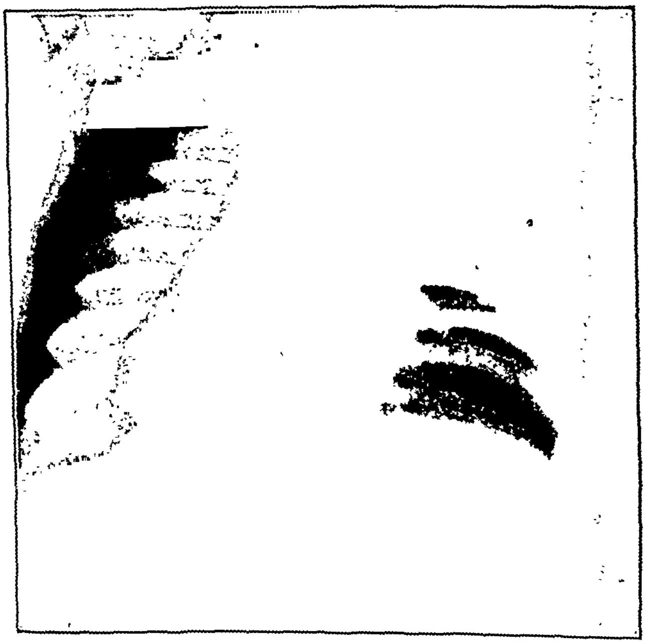

Fig. 8 (Case 8).—Consolidation of right upper lobe.

failed to show the presence of fluid in the pleural cavity by physical signs when it was exhibited by the roentgen ray.

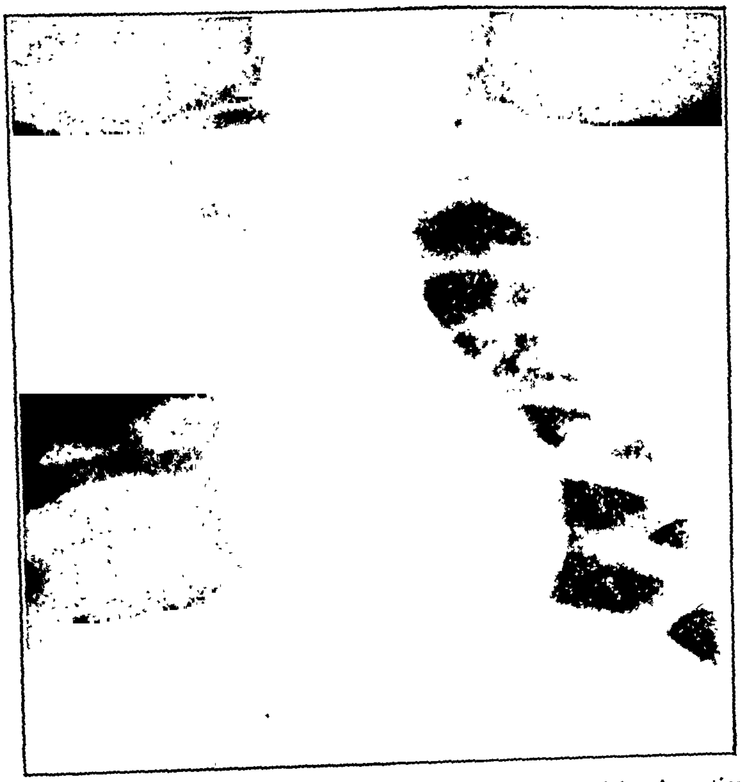

Fig. 9 (Case 9).—Partial consolidation of lower peripheral portion of right upper lobe.

As a general rule it was found that the roentgen ray would often give a showing in the absence of physical signs in congestions, small consolidations, hilum infiltrations, interlobular pleurisy, miliary tuberculosis and mediastinal tumors. The roentgen ray may be very helpful in these conditions when the physical signs are insufficient for a diagnosis.

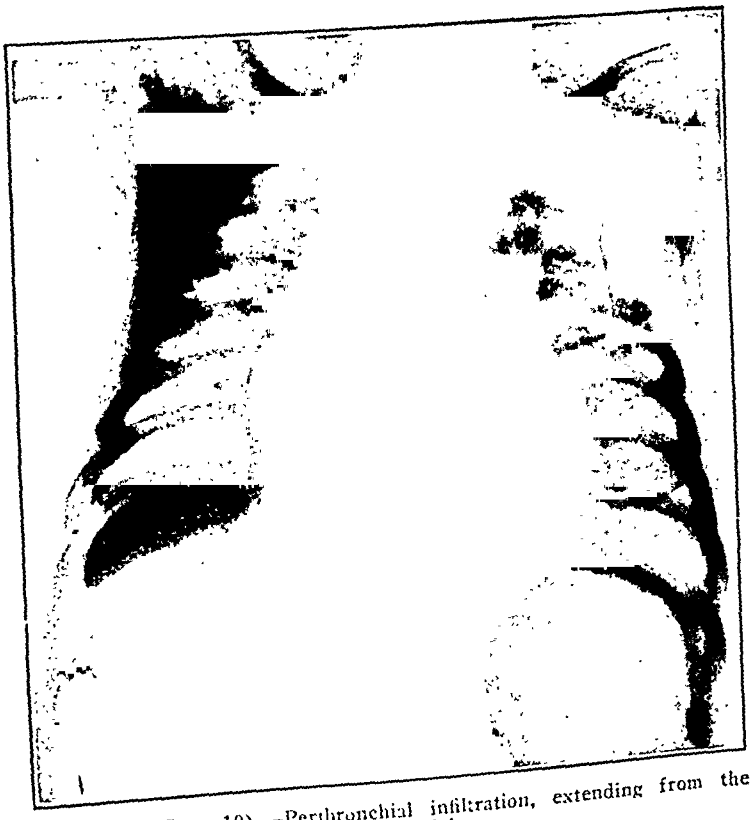

Fig. 10 (Case 10).—Peribronchial infiltration, extending from the roots into the right upper and lower lobes.

Auscultatory physical signs are, of course, not so apt to be accompanied by roentgen-ray shadows as are the percussion signs.

The following types of pulmonary affections may serve as examples of this study:

Case 5.—S. W., aged 2½ years, had increased breath sounds and moist râles posteriorly on the right, and sonorous râles on the left. The d'Espine sign was noted to the third dorsal vertebra. The von Pirquet test was positive. The roentgenogram revealed increased intensity and irregularity in outline in the hilum, especially on the right side. There were enlarged nodes and calcific deposits in the hilum. There was interlobular pleurisy between the upper and middle lobes on the right side. The triangle here shown with the base at the root of the lung is not due to pneumonia but to tuberculous infiltration. This form of shadow is not usually due to pneumonia at the base.

Case 6.—J. A., aged 9 years, was shown by the roentgen ray to have marked infiltration of the hilum on both sides with enlarged nodes and calcific deposits.

The difficulty of diagnosing hilum infiltrations and enlarged nodes in the mediastinum by physical signs is very great. The roentgen ray is here distinctly helpful. A study of the transmission of voice sounds below the seventh cervical vertebra, known as d'Espine's sign, in connection with roentgenograms, was made in eighteen cases by Dr. Edelman in our clinic.

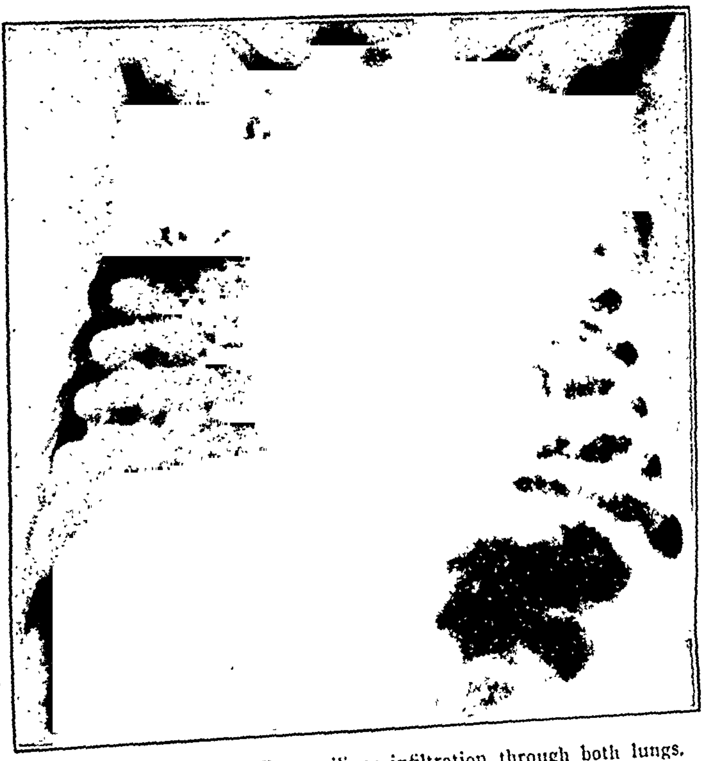

Fig. 11 (Case 11).—Diffuse miliary infiltration through both lungs.

The ages of the children varied from 2 years to 13 years. Five gave a tuberculous history and the rest were negative. All of the patients gave the d'Espine sign from the second to the fourth dorsal vertebra. The roentgen ray showed hilum infiltrations in fifteen of the cases. The von Pirquet test was positive in sixteen of the cases. Twelve of the children had had measles. Eight had had whooping cough, four had had both of these diseases, and four had had pneumonia. Fourteen of the patients had persistent cough, twelve had loss of weight, ten had fever, and three had night sweats. Eleven out of the eighteen patients had enlarged tonsils, and eight had decayed teeth.

The comparison here made shows that d'Espine's sign has considerable diagnostic value in diseased conditions at the root of the lung.

Case 7.—C. G., aged 8 months, had dulness over the right apex posteriorly, with slight increase in voice and breath sounds. There was no bronchial breathing. The roentgen ray revealed partial consolidation of the right upper lobe which did not extend to the root.

The physical signs and the shadow exhibited in this case confirm the observation of Dr. Mason that bronchial voice and breath sounds do not appear until the consolidation reaches the root. This is explained by the fact that sound is conducted much better through a medium of uniform density than in one of varying density. From studies made by Dr. Mason, he believes that the consolidation of pneumonia always begins in that portion of the lung that lies close to the pleura.[1]

Case 8.—S. S., aged 2 years, had harsh respiratory sounds over both lungs. There was dulness over the right apex, with bronchial breathing. The roentgen ray revealed complete consolidation of the right upper lobe.

Case 9.—J. W., aged 11 months, according to the clinical diagnosis had central pneumonia. There was no bronchial breathing. The roentgen ray revealed a partial consolidation of the lower peripheral portion of the right upper lobe. This case also exemplifies the contention that what is supposed to be a central pneumonia is really peripheral at the start. The absence of bronchial breathing is explained by the fact that the inflammation has not yet reached the root of the lung.

Case 10.—J. G., aged 8 months, had subcrepitant and sibilant râles all over the chest. There were irregular spots of dulness on the left side, and congestion of the left upper lobe. The roentgen ray revealed an infiltration, peribronchial in distribution, extending from the roots into the right upper and lower lobes. This was a case of bronchopneumonia.

In most of our cases the shadow of the heart was increased in pneumonia, especially in lobar pneumonia. The enlargement was usually most marked in the right heart.

Case 11.—P. S., aged 16 months, had a large number of moist and crackling râles over both lungs. The roentgen ray revealed diffuse miliary infiltration through both lungs.

The cases included in this study were taken from the New York Post-Graduate Hospital and Dispensary. Dr. William H. Meyer, head of the roentgen-ray department, took and interpreted the roentgenograms. I am also indebted to Dr. Edelman for aid in collecting the cases, and to Drs. Walker and Davison of the house staff.

Control of Communicable Diseases.—*Public Health Reports*, Oct. 12, 1917, contains the report of a committee of the American Public Health Association on standard regulations concerning the control of communicable diseases. This report, which is an extensive one, gives a list of the diseases communicable and reportable, and sets forth in detail information about each, covering the infective agent, source of infection, the mode of transmission, incubation period, period of communicability and methods of control. As a guide to health authorities in the preparation of local regulations regarding these diseases, the committee has established definitions of terms such as the following: cleaning, contact, delousing, disinfection, education in personal cleanliness, fumigation, isolation, quarantine, etc. Inasmuch as the laws under which the various departments of health operate require differences in the legal phraseology of rules, etc., formal regulations have not been prepared by the committee concerning each disease.

THE LIVER AND ITS CIRRHOSES

WILLIAM J. MAYO, M.D.
ROCHESTER, MINN.

The liver is the central metabolic laboratory of the human body responsible for the final preparation of nutritive material for conversion into tissue-building and energizing substances. A brief review of some of its anatomic and physiologic characteristics may not be out of place. The weight of the average liver in man is 50 ounces, with a normal variation of about 10 per cent. It may be assumed, therefore, that a liver weighing more than 55 ounces is increased in size and might properly be called hypertrophic, and one weighing less than 45 ounces might be called atrophic, unless such difference could be explained by the size, above or below the normal, of the person. If the weight of the liver is an indication of its metabolic activities, the liver of the female should be larger in proportion than that of the male, made so by the necessity of taking care of herself and her unborn child. As a matter of fact, the liver of the female is only one fortieth of the body weight, while that of the male is one thirty-sixth of the body weight. The hepatic artery is relatively a small vessel and has no corresponding veins. It is supposed to nourish the liver itself and, so far as its framework, the biliary channels and the gallbladder are concerned, this is undoubtedly true; but I have not seen anatomic proof that the liver cells are nourished by the hepatic artery. It would appear that the liver cells, in the process of acting on the blood brought to them through the portal circulation, receive nourishment direct, and that there is no distinction in this respect between the blood of the hepatic artery and that of the portal vein.

The portal system is made up of the gastromesenteric veins and the splenic vein, and it should be noted that the normal splenic vein carries to the liver from one eighth to one sixth of the total quantity of portal blood. The enlarged spleen has vessels in accordance with its size. The large spleens in certain splenomegalias may have vessels the size of the superior mesenteric artery and veins. This is most important, as it indicates that removal of the spleen relieves the liver of a large load of blood and, as shown by the results of splenectomies, this diversion to the general circulation may be sufficient to relieve the subnormal liver of its overload and enable the patients to return to a fair degree of health in otherwise fatal cases. Splenectomy establishes a new principle of treatment, namely, a reduction instead of a diversion of portal circulation, as accomplished in the experimental Eck fistula and the Talma,[1] Drummond and Morison[2] operation. The stomach and rectum each have a double vascular circulation, portal and systemic. Double ligation and division of the inferior mesenteric artery and vein where they cross the left common iliac vein or just beyond at the promontory of the sacrum, where the artery takes the name of the superior rectal, would greatly reduce the portal circulation. The artery is as large as the brachial, and in two-stage operations for cancer of the rectum, experience has shown that an enormous compensatory circulation is established with the general circulation through the middle and external hemorrhoidal vessels. Some effect might be produced by tying the superior coronary vessels of the stomach, thus increasing the return circulation about the esophagus, but this would be relatively unimportant and might increase the tendency to gastric hemorrhage.

To the liver has been given wonderful power of regeneration. If a considerable portion of the organ is removed, it will be restored by the remaining liver cells. Such regeneration has not been given to any other organ in the human body. When the necessity for work compensation is thrown on other organs, it is by hypertrophy of preexisting elements, not cell hyperplasia, that the stress is met. The outstanding feature of the hepatic cell is that there is no differentiation of the cells. Each liver cell is exactly like every other liver cell, and each normal liver cell is fully capable of bearing its portion of the work, here again differing from every other similar organ in which groups of specialized cells are to be found.

FUNCTIONS OF THE LIVER

Our knowledge of the function of the liver is very imperfect. We have learned something from experimentation. About postmortem conditions we know a great deal, but, as the liver cannot be removed in life, and as no attempt is made to remove any considerable portion of it except for disease, which vitiates the testimony, its functions have been most difficult to ascertain. The liver has five chief functions: (1) The metabolism of carbohydrates, (2) the metabolism of proteins, (3) the metabolism of fat, (4) the production of bile, and (5) the defense against bacteria, protozoa, and toxic chemical substances.

1. The glycogenetic function of the liver is most important in the final conversion and storage of carbohydrate derivatives in a form from which energy is most readily produced. The monosaccharids might be called the body coal which heats and energizes, the ash end-product, the carbon dioxid, being carried out of the system by the ventilating function of the lungs. Sugar is a threshold body always existing in the blood but appearing in the urine only when in excess of a definite percentage.

2. The amino-acids from protein digestion, of which eighteen have been described, are carried to the liver by the portal vein and, among other changes, the nitrogen-containing portion of the molecule is there converted into urea. The conversion of the nitrogen-containing portion of the amino-acids into urea is not carried on exclusively in the liver, but the liver seems to have a greater capacity than any other tissue for this reaction. Experimental work on the development of urea is most interesting and indicates that possibly the blood urea may act as a hepatic hormone in relation to protein metabolism. Cushny[3] states that urea is not a threshold body in the blood; that is, it is always to be found in the blood and in the urine. The amino-acids are used in tissue building. They are also converted into fuel and energy-producing substances. Plummer and Kendall[4] have shown that cellular activity is sparked, so to speak, by the thyroid secretion, hyperthyroidism overenergizing this activity, and resulting in a burning up of the tissues.

3. The fat function of the liver is not well understood. We know that sugar and fat are stored temporarily in the liver, ready for immediate use. It is probable, under certain circumstances, that carbohydrates are converted into fat in the liver. It has been shown that by forced overfeeding of carbohydrates the liver of the goose may be caused to become enormously fat, constituting a well known Teutonic delicacy. Osler[5] has pointed out that the carbohydrate value of beer, although small, is sufficient when enormous quantities are drunk to cause an immense storage of fat in the human liver, and that when this fat exists in connection with a deposit of connective tissue the portal cirrhosis which follows will develop a hypertrophic instead of an atrophic liver. In acute stress, such as occurs in phosphorus and chloroform poisoning, and massive infections, the liver may undergo a most rapidly fatal fatty degeneration. Its usual response to destructive insults appears to be acute fatty degeneration. In these first three functions, namely, the metabolism of carbohydrates, proteins and fat, the liver completes a process started in the gastro-intestinal tract. In the next two — the bile and defense functions — the spleen is associated with the gastro-intestinal tract.

4. It is difficult to state whether the production of bile is purposeful or a waste which contains by-products valuable in intestinal digestion. The bile pigments are derived from destroyed red corpuscles carried to the liver, partly from the spleen. At one time, the red blood cells of the body were supposed to be completely regenerated in from seven to ten days, the estimation being based on the total amount of pigments excreted in the bile. Recent investigations, however, cause some doubt regarding the accepted opinion that the bile pigments are all derived from destroyed red cells, and indicate that the red cells have a much longer life. The latter view agrees with the known results of blood transfusion in the anemias. When enormous quantities of blood are destroyed, as in hemolytic icterus, the liver, as well as the spleen, becomes greatly enlarged—a condition that has been confused with biliary cirrhosis. Accumulating evidence, however, goes to show that, while such a liver may contain an increased amount of connective tissue, it is not necessarily related to the biliary channels, and to a very large extent, the enlargement may be looked on as a work hypertrophy with hyperplasia of the liver cells. An interesting constituent of the bile is the lipoid cholesterin; a certain amount of cholesterin is always to be found in the blood, but the amount excreted in the bile varies greatly with the condition of the patient. In the pregnant female, as reported by Aschoff, cholesterin is greatly increased; this suggests its relation to gallstones, which are four times as common in women as in men, at the same relative ages, and in 90 per cent. of the female patients with gallstones, the first symptoms are related to a pregnancy.

5. The defense function of the liver is most important. Bacteria are constantly being carried to the liver from the portal circulation, and pigments of these slaughtered bacteria are found as nonhematogenous hepatic pigment areas (Adami[6]). The spleen strains out many bacteria, as in typhoid, and protozoa, especially the plasmodium of malaria and the spirochete of syphilis; but it may be unable to destroy these organisms, and they are sent to the liver for destruction. It seems fairly clear that, at least so far as portal cirrhosis is concerned, it is related to the defense func-

tion; the liver, losing power to absorb and eliminate diffuse poisons, attempts to encapsulate them, thus introducing the connective tissue. The spleen has been compared by Rowntree[7] to the glomeruli of the kidney, and the liver to the tubules, the one straining out the degenerated cells, micro-organisms and poisons, and the other acting on the material brought to it. The interrelated pathologic condition of the spleen and liver follows closely this interrelation of function.

CLASSIFICATION OF CIRRHOSES

The foregoing most prominent facts connected with the anatomy and physiology of the liver have been reviewed with the idea of throwing some light on the connective tissue diseases of the organ. First inaptly called cirrhosis by Laennec, on account of a tawny or yellow color which sometimes exists, cirrhosis is a term applied indefinitely and indiscriminately to almost any condition of the liver which is not understood, but in which there is an excess of connective tissue. The outstanding feature of all liver changes, the result of chronic irritation without regard to cause, is the deposit of connective tissue. This is well shown in the local cirrhotic processes which may accompany cancer, syphilis and tuberculosis of the liver.

The pathologic classifications are based on morphology, and the morphologic pictures are sometimes differently interpreted by the various authorities. To one who makes an attempt to understand the cirrhosis and who is interested in the living rather than the dead body, the pathologic descriptions are certainly far from illuminating. It is sometimes of benefit to be an amateur, in that an amateur may be able to see more clearly the larger elements, which are often lost in details; in other words, a better perspective is obtained. Generally speaking, fundamental types of cirrhoses may be distinguished; the others represent combinations or variations, rather than entities.

The two types are:

1. Portal cirrhosis, in which the chronic irritants, probably biochemical substances, are introduced through the portal vein, and in which circulatory disturbances are the most prominent clinical features, causing gastric hemorrhages, and especially ascites. Jaundice is seldom present and only as a terminal symptom.
2. Biliary cirrhosis, in which jaundice is clinically the chief symptom, ascites being absent or, if present, being a terminal condition, with the evidence pointing to an infectious cause.

In portal cirrhosis the connective tissue is introduced about the radicles of the portal vein, and in biliary cirrhosis, about the bile ducts. In both portal and biliary cirrhosis the spleen is often enlarged and has a causative relation in many cases, such as the terminal portal cirrhosis of the splenic anemias, the so-called Banti's disease.

I have never seen a case I could call Hanot's cirrhosis, and, so far as I know, this type of cirrhosis has no pathologic basis and little clinical evidence to support its existence. The large majority of cases that have taken the term of Hanot's cirrhosis are either hemolytic icterus or the ordinary type of biliary cirrhosis. As a matter of fact, hemolytic icterus, primarily a splenic disease with a work hypertrophy of the liver, has been confused with biliary cirrhosis and, as gallstones with recurring exacerbations of infections have existed in something like 60 per cent. of the cases in which we have removed the spleen for the cure of hemolytic icterus, this confusion has not been entirely without excuse. If we constantly bear in mind that, without regard to the nature of the irritant, the response in the liver is connective tissue formation, and that this may involve the whole liver or that it may exist locally, it may readily be seen where confusion has arisen. While typical portal cirrhosis, on the one hand, and typical biliary cirrhosis on the other, are well defined, atypical forms exist from mixed causes, as portal cirrhosis with secondary biliary cirrhosis from gallstone infections.

If hemolytic icterus is split off from the cirrhoses, and if it can be shown by further investigations, which our somewhat limited experience leads me to believe, that the enlargement of the liver which often exists in hemolytic icterus is a work hypertrophy and that the connective tissue formation present is not specific, much will have been accomplished in clearing up a vexed question.

Comparatively little work has been done on portal cirrhosis since the eighties, but during that period many interesting papers were written, especially by the French and English. Hilton Fagge[8] calls attention to a number of cases in which persons apparently in perfect health died suddenly from accidental causes and were found at necropsy to have had an extensive cirrhosis of the liver, suggesting some unknown factor not properly estimated. At operation I have occasionally found extensive cirrhosis of the liver unrelated to the condition which called for the operation and apparently not of immediate clinical importance.

COMPARISON OF PORTAL AND BILIARY CIRRHOSIS

It is probable that the relation of stimulants to cirrhosis of the liver, at least in this country, has been exaggerated. I have seen a considerable number of cases of portal cirrhoses in nonalcoholic young persons. Fagge shows that in Guy's Hospital for twenty-five years 14 per cent. of those dying from portal cirrhosis with ascites had complicating tuberculous peritonitis. Cheadle[9] and others have shown that, while the Laennec type of atrophic cirrhosis stands at one end of the group, representing the typical gin or hobnail cirrhosis of the liver, as many cases are to be found in which the weight of the liver is increased as there are those in which it is diminished, and the belief that such huge livers finally contract down to the Laennec type is unfounded. It is, of course, quite probable that, in the hepatitis which early accompanies the deposit of connective tissue, the liver would be somewhat enlarged before contraction. But that this is at all true of the massive livers, and especially of those containing quantities of fat, as seen in the beer drinker, cannot be credited. Our better understanding of the atrophic type of portal cirrhosis has led us to underestimate the frequency with which the cirrhotic liver is increased in size and weight. In biliary cirrhosis the liver is always enlarged. The margin of safety in the liver is very great. The patient with portal cirrhosis rarely dies from insufficiency of hepatic tissue, but death is usually brought about through changes in the circulation, and secondary complications, while in biliary cirrhosis death results from chronic jaundice and cachexia. The establishment of compensatory circulation by which blood would be passed from the portal vein around the liver into the general circulation, as advanced and pictured by Talma, Drummond and Morison, has given marked palliation in suitable cases. Sappey has most accurately described the venous avenues by which such compensatory circulation is brought about through nature's unaided efforts. Eck's fistula, that is, the establishment of a bypath between the portal vein and the vena cava, is purely experimental. It is of interest that in all the cases I have seen in which portal cirrhosis accompanied splenic anemia, the cirrhosis was of the atrophic type of Laennec.

[9] Cheadle, W. B.: Some Cirrhoses of the Liver, Brit. Med. Jour., 1900, 1, 754-757; 824-826; 893-898.

In fifty-one cases of splenic anemia, in which we have removed the greatly enlarged spleen, the relief to the portal circulation has been immediate. In those cases in which cirrhosis was present, the ascites has now disappeared and several patients have lived for years, one for more than seven, in excellent health. The evidence here points to the fact that the original poison was carried to the liver from the spleen and theoretically is probably a protein derivative, filtered from the blood. But in five cases of portal cirrhosis with ascites, in which I removed the enlarged spleen, the four patients who recovered were greatly improved both as to their general condition and as to the relief of the ascites. On first thought, it seemed probable that in the removal of such a spleen I had checked the source of poisoning. On further consideration, another explanation appears possible or even probable. With the removal of the spleen, all the blood from the general circulation, which otherwise would have been sent to the liver through the splenic vein, was prevented from going there, and in this manner sufficient blood had been diverted from the liver to relieve the portal circulation. Possibly both views are more or less correct. The results in these cases should encourage us to splenectomize in suitable cases of portal cirrhosis in the future, especially when the spleen is enlarged.

Biliary cirrhosis, of the obstructed or acutely infected type, is easily understood. It exists in connection with gallstones, particularly those in the common duct, and jaundice is an early and continuous feature. In many of these cases, however, the patients are not cured by the removal of gallstones and biliary drainage. More or less permanent damage has been done to the ducts, resulting in chronic areas of infection and often in deposits of stones in the bile ducts, until thousands of such stones may be found in the liver. A second type, which is not so well understood, accompanies certain chronic biliary infections. In these it would appear that either primary hematogenous infection of the bile ducts took place or that there was an extension from a chronically infected gallbladder to the ducts. Rosenow's[10] work in revealing the specificity of bacteria, and in showing that the bacteria, usually streptococci, are to be found in the walls of the gallbladder and ducts and not in the bile, is most important. Large, soft lymphatic glands are usually to be found along the common duct and in the fissure of the liver. In chronic biliary cirrhosis, the liver is large and the walls of all the biliary ducts are extremely thick. In one instance, the lumen of the common duct was reduced at least one half by the deposit of connective tissue in the wall of the duct. Every grade of biliary cirrhosis may be found in this chronic type, which is much more liable to be accompanied by an enlarged spleen than those dependent on the more acute infections of the common duct. Not infrequently, chronic pancreatitis will be present from coincident infection. I have seen cases of this description in which there was apparently much improvement by prolonged biliary drainage to the surface, or by a cholecystogastrostomy or cholecystoduodenostomy; but as the clinical course of these patients is very chronic, I am not at all sure that cause and effect are properly related. In five cases of this type, in all of which the spleens were enlarged and the patients were more than 35 years of age, I performed splenectomy. All were improved, the jaundice was greatly reduced, though it had not entirely disappeared in any case, and the liver remained more or less enlarged. There are two possible explanations of this improvement: 1. The source of the chronic infection may have been focal at some point in the body and the toxic material resulting may have been continuously strained out in the spleen and sent to the liver, continuing the infection there. Such cases are occasionally seen in diseases that follow infectious diseases, for example, pneumonia. 2. When the spleen was removed, there was a large reduction in the necessary work to be performed by the liver.

The confusion which has arisen between biliary cirrhosis and hemolytic icterus has somewhat of a parallel in the failure to differentiate those ascites due to polyserositis (Concato's disease) and portal thrombosis from portal cirrhosis. Fagge states that for every three cases of portal cirrhosis with ascites, he saw one of ascites from polyserositis. Concato's disease may be recognized by the thick white peritoneum, by the intestines with greatly shortened mesentery clustered about the spine, and by the encasement of the liver and spleen in a thick white fibrous membrane. Free fluid is usually to be found in both pleural cavities. Pick's syndrome often exists, in which pericardial adhesions hamper the heart's action. The fact that, in some of these cases, the liver is completely encapsulated leads the uninitiated to believe that some form of cirrhosis is present; but, on excision of the strangling membrane, the liver will be found normal.

Warthin[11] has pointed out that thrombosis of the portal vein or some of its branches occasionally occurs with ascites, being a chronic malady accompanied by liver changes and splenomegalia, and usually confused with portal cirrhosis or splenic anemia.

Egg Substitutes.—Cooking tests and analyses of egg substitutes were made by the laboratory of the Kansas State Board of Health, the results of which are given in the *Bulletin* for March. In the experiment of making sponge cake with no baking powder and replacing half the usual number of eggs with egg substitute, the cake stuck to the pan when done and did not have the other characteristics of true sponge cake. In another test, baking powder was used instead of eggs and egg substitute, with a like result. Averaging the price of seven egg substitutes, the analyses of which are given, the *Bulletin* says the consumer pays more per pound for the substitute than he would per pound for the dry material of hen's eggs calculated at 40 cents a dozen. The so-called substitutes are chiefly starch (70 to 90 per cent.), whereas the dried matter of eggs is essentially protein and fat. An analysis of a substitute called "eggette" showed to be false the manufacturer's assertion on the carton that the contents of the package was equivalent to twelve eggs. On the basis of protein value, the substitute was shown to be equal to only 1.7 egg; on a basis of fat, it was equal to only 0.14 egg, and in fuel value it was equal to only 2.6 eggs.

IMPORTANCE OF SIGMOIDOSCOPE IN DIAGNOSIS OF DISEASE IN TERMINAL COLON AND RECTUM

WITH A DISCUSSION OF TWO HUNDRED AND FIFTY-ONE CASES

GOLDER LEWIS McWHORTER, M.D., Ph.D. in Surgery
Instructor in Surgery, Rush Medical College
CHICAGO

This study is based on a series of patients whom I examined with the protoscope or sigmoidoscope while at the Mayo Clinic, 1917. The patients, with few exceptions, had not been examined with special instruments, though nearly all of them complained of some symptoms referable to the terminal bowel or to some disease in this region. The failure to detect early the large number of diseased conditions in the terminal colon results from a neglect to examine all patients with the sigmoidoscope, however slight the symptoms. At the time of examination, I noted the chief complaints and findings, and, after the discharge of the various patients from the clinic, I reviewed carefully the histories, noting the findings, diagnoses and results of treatment. In Table 1, I have classified all cases examined, as shown by the final diagnosis, but in this paper, shall take up only those grouped under A, B, C and D, because of a lack of space for lengthy consideration of all cases, and because of the greater importance and gravity of the diseases in these groupings.

Disease of the large bowel is most commonly located (exclusive of the appendix) in the rectum and sigmoid; consequently, its presence may usually be determined by inspection of this region. Leichtenstern[1] states that in 770 cases of intestinal carcinoma, 616 were in the rectum, 89 in the colon, 32 in the cecum and appendix, and 33 in the small intestine. Out of 89 cases of colon carcinoma, 42 were in the flexura sigmoidea, and 30 in the transverse, 11 in the descending, and 6 in the ascending colon.

While a number of disease conditions may be discovered by the examining finger, yet inspection by means of a protoscope is necessary in the majority of cases before a definite diagnosis may be made. The majority of carcinomas are beyond reach of the finger, yet well within observation by the protoscope or sigmoidoscope. In a series of 100 consecutive cases of carcinoma of the rectum and rectosigmoid removed at St. Mary's Hospital, 63 per cent. involved the rectosigmoid region.[2]

Twenty-two cases of my series (Table 1 A) were diagnosed carcinoma, and in only one was the carcinoma located beyond reach of the sigmoidoscope. This was removed after a roentgen diagnosis of probable carcinoma or diverticulitis, the carcinoma being located in the upper part of a long sigmoid. The appearance of carcinoma is usually quite characteristic, with an annular or oval ulcerated growth elevated at the edges, and a cauliflower-like appearance of the granulation tissue. In later stages, the growth may produce an almost complete stenosis of the bowel; but careful inspection of the everted edge and irregular surface of the ulcerated growth, which is hard, friable, and either circumscribed or diffuse, establishes the diagnosis. The appearance of carcinoma after radium exposure is somewhat different. The surrounding tissues are edematous, somewhat indurated, and instead of the ulcerated surface having a cauliflower-like appearance, it is quite smooth and glistening, while the new growth is less resistant, edematous and not so sharply circumscribed. The history of the disease and the application of radium, in connection with the proctoscopic examination, will enable the making of a definite diagnosis, and only in exceptional cases is it permissible to remove tissues for microscopic examinations.

The chief complaints in these cases (Table 1 A) were blood in 21, constipation in 15, pain in 10, usually in the rectum but in 1, in the lower abdomen, pencil stools in 9, hemorrhoids in 5, and, in 2 cases, a long existing diarrhea. The duration of symptoms was about eight months, though in four cases, the average was only three months. In a review of 491 cases of carcinoma of the rectum and pelvic colon, Lynch[3] found the average duration to be more than eight months.

In twenty cases of chronic colitis (Table 1 C) the *Endameba hystolytica* was found. The appearance of the bowel in colitis due to the ameba is not characteristic, but in some cases in which there are multiple small oval or round ulcers, some mucus, a hyperemic, easily bleeding surface, and some edema of the wall, the ameba may be correctly diagnosed as the cause. Many cases proved amebic are of slight severity or are limited to a slight proctitis, the sigmoid appearing normal. In two of these twenty amebic cases, the moderate inflammation was limited to the rectum, and roentgenoscopy revealed no changes in the colon. From the experimental production of amebic colitis in kittens, Dale and Dobell[4] found the upper and lower third of the colon most involved, especially the latter. Lynch and McFarland,[5] in reporting chronic colitis with negative stool examination, state that in the unclassified nonamebic colitis, the sigmoid is most involved. Some of the amebic patients examined had evidences of previous severe inflammation in folds of hypertrophied or atrophic and scarred mucosa, two patients having generally contracted and rigid colons. Considerable care was used, especially in the latter cases, in passing the sigmoidoscope, to prevent tearing the mesentery or wall.

The chief complaints in the twenty amebic colitis cases were diarrhea in 14, epigastric or diffuse abdominal pain in 11, rectal pain in 1, blood in 6, mucus in 4, alternate constipation and diarrhea in 2, constipation in 1, pus in 1, gas in 1, and frequent urination in 1. Sanford[6] found in 41 per cent. of persons affected with ameba in the temperate climate a history of constant diarrhea, in 33 per cent., intermittent diarrhea, and in 26 per cent., no bowel trouble at all except constipation, the whole syndrome being less severe than in the South or the tropics. Whitmore[7] emphasizes the grave danger of the rapidly increasing number of carriers of *Endameba histolytica* in camp life, including many who have no intestinal symptoms. He states that from 20 to 25 per cent. of dysentery on the Eastern front is due to the endameba, and that carriers are very resistant to treatment.

Thirteen patients with *chronic colitis* (Table 1 D) showed no specific organism on repeated stool examinations; consequently, they are grouped separately. Four of this group were clinically diagnosed as having amebic colitis, the remainder being classed under unknown etiology. In comparing the unclassified with the amebic group, I found the severity of the colitis much less in the latter. Only one amebic case was severe enough to require ileostomy, while in the much smaller number of unclassified chronic cases, two patients were operated on in this manner. This severe chronic colitis must not be confused with the mucous type, in which no actual inflammatory changes are seen, and for which Simon[8] has suggested the name myxoneurosis. There is a true inflammation of the mucous membrane in these chronic cases of colitis, complicated by infiltration of the wall, and perhaps by peritonitis, with oftentimes erosions and ulcers as secondary changes. The stage between a simple and a severe colitis is a very gradual one.

Roentgenoscopy is of value in chronic colitis because of its aid in determining predisposing causes, as stasis, chronic obstruction, and diverticula, or in estimating the extent and amount of involvement due to secondary changes. Kienböck[9] describes two types of colitis ulcerosa as determined by the roentgen ray from five to twelve hours after the meal, immediately after, and one hour after, an opaque enema. (The use of the enema for roentgenoscopy should be avoided in very acute or severe chronic cases, as it may lead to perforation.) The colon, in the first type described by Kienböck, is narrow, may be spastically contracted, and is nearly or entirely haustraless with uneven flecking of the edges; in the second type, it is relatively broad, and almost invisible, owing probably to its being filled with slimy mucus and nearly bismuth-free contents; or, if visible, it presents the appearance of a very light, haustraless cylinder, owing to its being filled with air, and has a characteristic uneven bismuth flecking throughout. In chronic ulcerative colitis, Kienböck found the progress of the bismuth retarded in the ileum after a meal, and accelerated in the colon, others having found the same to be *true*.

The chief complaints found (Table 1 D) were diarrhea in 12, blood in 7, abdominal pain in 3, mucus in 4, some incontinence in 2, and alternate constipation and diarrhea in 1. Concerning the etiology of severe colitis with negative stool examinations, it is significant that Strauss[10] in working on the serologic reaction, found a positive agglutination test consistently against the various types of dysentery, paratyphoid and typhoid bacilli in both acute and chronic cases. In only one case, that of an acute type, did he find the corresponding organism in the stool.

POLYPI AND CARCINOMA

An interesting group is seen in Table 1 B, and is elaborated on in Table 2. In this series are thirteen cases, in twelve of which polypi were present and in one of which there was no recurrence observable from the base of a polypus removed several months before. In one (Case 9) there was a recurrence of a polyp fulgurated ten months previously. Severe multiple polyposis was found in one (Case 11) in which deep ulcerations and a severe inflammation of the colon later became complicated by multiple perforations and ended in death. In the remaining cases there were only solitary or a few scattered polypi; however, there is significance in the fact that in three of these (Cases 2, 3 and 7) a carcinoma was also present. While multiple polyposis of the colon has been recognized for many years as a serious disease because of the frequent consequent development of carcinoma, the importance of the association of isolated or of a few scattered polypi with carcinoma has not been emphasized; consequently, the treatment of these polypi, and of local inflammation, has been neglected.

Whether the same conditions call forth both carcinoma and polypi, whether the carcinoma is secondary to the polypi, or vice versa, has not been established. Recently, Soper,[11] in reporting a case of his own, reviewed the literature of multiple polyposis, and found sixty cases. Carcinoma was present in 43 per cent. of these, appearing much more frequently in the rectum. The etiology of multiple polyposis is not

clear. Although most frequent in young persons, yet even here there is early carcinoma involvement. That there may be some familial relationship between carcinoma and multiple polyposis is shown by Doering,[12] who reports that out of fifty patients, eight were members of families in which other members had died from carcinoma of the rectum. The polypi vary from the size of a pigeon's egg to very minute dimensions.

Most authors classify two chief types of polypi and believe that either type may occasionally be multiple, producing the disease multiple polyposis. In the first type, the adenoma or increased gland formation may form a superficial infiltration into the wall, or else project as a polypus. In the second type, the polypoid tumor is composed of solid connective tissue from the submucosa, or of branching tufts covered with more or less indifferent mucosa. Here, also, there may be tubules lined with cylindric epithelium resembling an adenoma.[13] Some authors[14] think that the condition of multiple polyposis does not originate in the isolated type of polypi, and that the multiple polyposis tends specifically to the development of carcinoma. In gastric polyposis, Finney and Friedenwald[13] report that polypi of the stomach are usually benign in character; but they observed one of two cases reported to be undergoing carcinomatous degeneration. Delafield and Prudden[15] state that in some adenomas of the colon the tubules are irregular in shape and arrangement, and the growth infiltrates the surrounding parts, and that there is no sharp line between these tumors and carcinomas.

It is the belief of many that these polypi originate from congenital rests, and are absolute new growths.[16]

Versé[17] assumes a congenital predisposition of the epithelial cells to increased proliferation, which through stimulation by chronic inflammation leads to polyp formation. Borelius and Sjovall[18] conclude that all supposed characteristic differences between polypi of primary new growth and those secondary to inflammatory origin are shown untenable, and that there is no hindrance to the belief that all intestinal polypi can start on an inflammatory basis. Wechselmann[19] thought that the inflammatory hyperplastic polyposis, as contrasted with new growths, was limited to the mucosa possessing no pedicle from the submucosa. Borelius and Sjovall, however, showed that in a case with varying degrees of inflammation, both conditions were present, the pedicle coming from the submucosa as a result of the more extensive inflammation. Multiple polyposis of the colon may occur secondary to inflammatory changes in the mucosa, by the scarring and the mucosal excrescences in dysentery and tuberculosis.[15]

While the adenomatous type of polypi may degenerate into carcinoma more frequently, the connective tissue polyp is also associated with malignancy; and while the epithelium may appear indifferent, the polyp or the conditions producing it may also predispose to

TABLE 2.—THIRTEEN CASES, IN TWELVE OF WHICH ISOLATED OR MULTIPLE POLYPI WERE PRESENT

No.	Chief Complaints	Polypi	Number of Polypi	Age	Sex*	Complications	*Remarks*
1	Blood in stools, diarrhea and bowel distress, 1 year	1 in rectum; 4 or 5 in lower sigmoid	5-6	26	♂	Severe colitis	On examination, one polyp found to be an adenoma
2	Blood and hemorrhoids, 10 years; pain in rectum, 1 year	5 or 6 in rectum and lower sigmoid; bean sized to hazelnut	5-6	43	♂	Carcinoma, 5 cm. up rectum	Kraske operation done
3	Hemorrhoids, 10 years, constipation and blood, 9 months	1 sessile pea sized rectal polyp	1	47	♂	Carcinoma, 3 cm. up rectum	Metastases found in liver; chronic inflammation in polyp
4	Abdominal pain, diarrhea and mucus	1 in lower sigmoid	1	29	♂	Spastic sphincter	
5	Diarrhea, 3 years	1 small polyp in lower rectum	1	55	♂	Ameba histolytica present	On examination, polyp shows chronic inflammation
6	Constipation and hemorrhoids 20 years; blood, 1 year	1 lower sigmoid, bean size; 2 small ones, lower rectum	3	39	♂		
7	Hemorrhoids, pain, blood and ribbon stools, 1 year	1 bean sized in lower rectum	1	67	♂	Carcinoma, 8 cm. up rectum	Tube resection of bowel done (peritonitis)
8	Piles and spasm of sphincter	1 bean sized in lower rectum	1	30	♂	Hemorrhoids	
9	Slight incontinence of feces	1 pea sized, upper rectum, recurrent; 2-3 small ones, lower sigmoid	3	58	♂		Recurrence of one polyp fulgurated 10 months before
10	Diarrhea, constipation, mucus and blood, 2 years	1 bean sized in lower rectum	1	20	♀	Severe ulcerative colitis	No amebas found
11	Severe pain, diarrhea, blood and mucus, 8 months	Extensive, ulcerative, polyposis colon	Multiple throughout colon	55	♀	Multiple perforations one month later	Pathologically, extensive diffuse papillomatous colitis with multiple ulcers and perforations
12	Severe anemia and loss of strength	1 bean sized, upper rectum; 1 smaller, lower sigmoid	2	63	♂		
13	Rectal distress	Polyp previously removed and hemorrhoids operated on 3 times	None now seen	45	♂		Previous removal of polyp and hemorrhoids; no recurrence

* In this column, ♂ denotes male and ♀ female.

carcinoma. In Table 2, Case 1, in which a severe colitis existed, one of the polyps was found to be adenomatous. In Case 11 it was papillomatous in type, while in Case 3 there was found chronic inflammation in the polyp associated with a cancer.

A few writers report solitary or a few scattered polypi associated with carcinoma, but mention their benign character. As mentioned above, in three of my cases (Table 2, Cases 2, 3 and 7) a carcinoma was present when there were solitary or a few scattered polypi. The unusual frequency of carcinoma with solitary or scattered polypi should be emphasized, for there probably is only a difference of degree in the proper stimulation, such as chronic inflammation or trauma for producing either solitary polypi, or a very grave disease, multiple polyposis. Since carcinoma develops early in about one half of the cases of multiple polyposis before they terminate in other complications, some specific predisposition must exist. Prophylactic treatment against all causes of chronic irritation or inflammation of the rectum and sigmoid, and active treatment in all stages of polypi, are advocated.[20]

Clinical Notes, Suggestions, and New Instruments

REPLACEMENT OF SCALP ON A DENUDED DRY SKULL BY GRANULATIONS SECURED THROUGH HOLES DRILLED IN THE BONE

T. C. Davison, M.D., Atlanta, Ga.
Associate Professor of Surgery, Emory University School of Medicine; Visiting Surgeon, Georgia Baptist Hospital; Associate Visiting Surgeon, Grady Hospital; Major, M. R. C., U. S. Army

In this case there was successful development of a covering of granulation tissue and epithelium over a skull dome, the bones of which were exposed, dry and undergoing necrosis. Grafts could not be attempted because of the bones' condition, and the usual tissue and blood supply for flaps in this area had also been destroyed.

The clothing of a girl of 6 caught fire. She threw herself, face downward, under the bed and protected her face by her right arm. The lower edge of the burned area extended across her back from the right lower costal margin to the angle of the left scapula. From this line the burn extended upward and, besides the head and neck burns, involved the back of both shoulders, more especially the right, and the extensor surface of the right arm. On the head and neck the burns and resultant sloughs involved the nape and right side of the neck, the scalp over the occiput to an irregular height of about 1 inch above the occipital protuberance, and the right ear. A ribbon-like burned area about an inch wide and an inch above the eyes extended across the right temple and forehead and caught the left ear in its subsequent scar. The left postauricular area was the only part of the base of the scalp that did not later slough, and the left posterior auricular artery was the only blood supply to the scalp not destroyed. The face, protected by the arm, escaped injury and remained uninvolved throughout. The scalp above the occiput, except for the ribbon-like burn, escaped immediate injury, though later sloughing.

At the time of the child's admission to the hospital, three weeks after the burn was received, the burned area was a mass of infected, sloughing tissue giving off a very offensive odor and, because of the child's intractability, requiring six nurses to dress. The burns were treated antiseptically until healthy, and then those on the back, shoulders, neck and right arm were successfully skin-grafted. Because of the lack of any blood supply except the left posterior auricular artery, the scalp over the crown, above the burned area, underwent dry gangrene, and, much like a piece of leather, was painlessly pulled off by the attending surgeon two weeks after the hospital admission, the pericranium sloughing with the mass. The removal of the slough left the bone bare for an area of approximately 4 by 6 inches. The wounds around the bare bone became healthy; granulations spread out, but, for the lack of circulation, they extended only a short distance over the denuded area. The bone began to undergo necrosis and softened in spots, but at the same time granulations appeared through the two parietal foramina and, to a slight extent, through the suture line between the two parietal bones. This suggested that if there was enough foramina there would be enough granulation to cover the surface. Skin for flaps was not available, the skin of the neck having already been destroyed; Tiersch and pinch grafts would not grow on the dry and softening bone. So, instead, I drilled about fifty holes through the dry calvarium at the intersection of squares measuring 1 cm. each way. The purpose of the drilling was to obtain a blood supply; so when blood was drawn the drilling stopped. In the softened areas, over the parietal eminences, the drill at times went through more quickly than expected, punctured the dura, and permitted the escape of cerebrospinal fluid.

The immediate postoperative reaction was a rise of temperature reaching a maximum of 105 F., but lasting only twenty-four hours. Aside from this there was no postoperative symptom nor suggestion of meningeal complication.

Careful daily observation of the drill wounds was made. On the fifth day granulations began to appear in many of the holes; in other holes, granulations were delayed; and through some of the holes in the softened areas over the parietal eminences no granulations appeared at all. The granulations grew rapidly, spread out, mushroom-like, over the denuded area, and where they met they fused, thus gradually, over a course of weeks, covering the whole area. In trimming off exuberant granulations, the scissors encountered gritty resistance, as though from developing bone. The epithelium, unaided by grafts, extended from the slough edge upward over the granulations toward the dome for an irregular height of from 1½ to 2 inches. The remainder of the area over the vertex was covered in by pinch grafts, three attempts in all being necessary. Tiersch grafts, first tried, were entirely unsuccessful in this area, though successful on the back, arms and neck. It was impossible to control the child, and she destroyed many of the grafts mechanically.

Over the right parietal eminence there appeared a thickening which threatened to become a bony tumor. This stopped growing after the area covered over, and though it persists, it is not enlarging. A slight growth of hair, irregularly distributed, has appeared over the grafted area.

The child was admitted to the hospital in December, 1915, and was discharged the following July.

The Uric Acid Theory.—It is an extraordinary attribute to Alexander Haig that the curious heresy which he invented and preached should have been blindly accepted by two generations of his medical brethren, and have ultimately become an obsession with the laity. And the tribute is the more astounding from the fact that the treatment which the heresy demanded entailed, according to the hitherto accepted standards, very considerable self-denial. Moreover, the heresy appealed not only to the faddist. The sane, sober, commonsensical doctor accepted it, in spite of the fact that he had never been taught it in the schools. The awakening was a long time in coming; but it came, and now one seldom hears of uric acid, except from a patient.—Sinapis in *Medical Press and Circular*.

Military Medicine and Surgery

THE WAR NEUROSES

WILLIAM B. TERHUNE, M.D. (Jackson, La.)
First Lieut., M. R. C., U. S. Army; United States Base Hospital No. 5
France

Few subjects have attracted more attention in medical circles since the beginning of the war than the war neuroses. Each belligerent nation has been confronted with the problem of caring for large numbers of soldiers afflicted with marked nervous manifestations resulting from the strain of war.

The careful consideration of this form of nervous and mental instability was found to be of military as well as of medical importance. The military authorities wished to know how this condition might be prevented, what percentage of men would be cured and how soon, and to what degree an individual was responsible for his actions while he was so afflicted.

The armed forces of the United States must now, by force of circumstances, consider the same problem, and while much has been written concerning this matter, I believe that a description of how the condition is actually cared for in the English army at the present time may be of value.

NOMENCLATURE

There being no definite knowledge of the neurologic pathology of this disease, and the psychologic processes being largely surmise, numerous terms have been suggested. Most of these are simply an effort to suggest a name that is descriptive of a syndrome, and many of these names depend to a large extent on an individual view regarding neuroses in general.

Eder makes use of the term "war strain," and then subdivides this into groups classified according to freudian principles.

Babinski has originated the word "pithiatism" to describe a hysteroid state in which the symptoms are the result of suggestion and may be relieved by suggestion. All other forms of the war neuroses he has designated as "reflex nervous disorders," and believes that they are on the border line between functional and organic disease.

The British medical offices consider the disease as purely functional in nature, and employ the terms "shell shock" and neurasthenia" as a classification, the differentiation depending primarily on whether or not the individual has been exposed to extraordinary strain.

The statement has been made that the use of "shell shock" as a diagnosis has resulted in an increase in the prevalence of the disease, and chiefly because of this the name is not used until the patient has been carefully examined in a hospital especially devoted to the treatment of nervous disorders, and not then until information has been obtained from his unit verifying his own statement as to how his illness arose. It is conceivable that malingerers will attempt to imitate this condition when it is remembered that many men at the front suffer from mild forms of it, and that a man who wishes to shirk his duty may easily exaggerate these mild symptoms. Such cases are usually discovered either by the battalion medical officer, or at the casualty clearing station, and the men are from there returned to their units. Such, however, is not always the case, and therefore, until a decision is reached that there can be no doubt as to the genuineness of a man's complaint, he is classified as "N. Y. D. N.," or "not yet diagnosed, neurotic."

PREDISPOSING CAUSES

It should be understood that to suffer from shell shock does not necessarily stigmatize an individual as neurotic, although it is undoubtedly true that many of these patients have suffered from various forms of mental instability in civil life and that others are burdened with a bad family history. A certain number of cases occur in men whose life history evidences an inadequacy in coping with the ordinary difficulties of life. Laudenheimer states that 90 per cent. of the patients were predisposed before joining the army; Forsythe says 100 per cent.; Mott, 66 per cent.; Eder, 30 per cent. However, some of the most courageous men apparently free from all neurotic tendencies, are afflicted with this malady. The disturbance occurs among commissioned officers, noncommissioned officers and privates, and if there was a question as to the frequency of occurrence in the various ranks I would be inclined to say that a relatively larger percentage of the noncommissioned officers were affected than of the others, and yet the noncommissioned officers are men chosen especially for their bravery and dependability.

To understand shell shock it is necessary to understand the conditions under which the men live at the front. They are constantly under a strain, both from a physical and mental standpoint. For several miles behind the line there is no place of absolute safety; sleep is often out of the question, not only because of the enemy's shells but also because of the noise of their own guns. The shrill shriek of the shell is a distinctly unpleasant sound, and the knowledge that bombing experiences, such as they have already passed through, may be repeated at any time does not tend to increase their mental composure. The men often continue to dodge shells after being admitted to a hospital, so vivid is the memory of them; nor is it so very unusual for a man, dazed by his experiences, to assert that bombs were dropped near him the night before, when as a matter of fact none have fallen in the vicinity for days. Fatigue is also a very important predisposing cause. It is not unusual for a man to state that he has had very little rest for several days previous to the development of his neuroses.

It should be remembered that one of the greatest factors in the development of a neurosis is intense and frequently repeated emotion; indeed, it is very doubtful if psychoneuroses occur as the result of fatigue unless associated with intense emotion. Fear is one of the strongest of the emotions; and while it may be repressed, nevertheless it exists and exerts its influence on the individual. Connected with this will be found sympathy for fallen comrades, disgust caused by death and dirt, anger, depression, concern about the relatives at home and in the army, remorse for past conduct, and fear that one will not be able to do one's part in the future as bravely as one might wish. And all the time the soldier must necessarily smother these thoughts in his own bosom.

It is true that the men at the front are all more or less subjected to the same physical and mental strain, but it is conceivable that a psychoneurosis can be produced by stress [illegible] ternal conditions acting on a mind only a degree more sensitive than that of the average person.

REPORT OF CASES

The following case histories are related in order that the picture of the condition may be made as clear as possible:

Case 1 (No. 242939).—An infantryman, aged 35, whose civil occupation was that of a window draper, whose total service in army was eight months, and who had been in France four months, had always been of a nervous disposition. He was married, and had two children, both of whom were well. He was very fond of athletic sports. His father was a drunkard. The patient had taken part in two raids on the enemy's trenches, and was once caught in a barrage fire, but was able to carry on his duties without feeling any ill effects.

While he was in a strong point in the front line trenches, with a machine gun squad, a shell fell within 6 feet of him; his companions were killed, he was buried, and he then lost consciousness for several hours.

He complained of being nervous and jumpy, had a severe occipital headache, was partially deaf, was dizzy, his teeth were very sensitive, he was constipated, he slept very poorly in the daytime, waking up with a start, and he could not sleep at all during the night. The pulse was 100, and the respiration, 18. The heart was three-fourths inch to the left of the midclavicular line. The hands were cyanosed, the strength less than the development, there were fine tremors of the fingers, the deep and superficial reflexes were lively, and the pupils were normal in size and reaction.

This is a typical mild case. The patient returned to his unit a few weeks after admission. The next was more severe:

Case 2 (No. 74963).—An artilleryman, aged 29, whose civil occupation was that of a blacksmith, whose total service was eighteen months, and who had been in France seven months, had suffered from a mental breakdown seven years before, during which he was compelled to stop work for a few months. The family history was negative. He had been in many dangerous places since his arrival in France, and had been repeatedly shelled. He was stepped on by a runaway horse a year before admission.

He was in the trenches for three days, during which time his position was continually under shell fire. The second day a shell fell about 10 yards from him and he was almost smothered by the flying dirt. The next day another shell burst near him; he was knocked over, became unconscious and had to be carried to the dressing station.

He complained of pain in the left side of his chest, the legs ached and felt useless, he had frontal headache, he was dizzy, weak and tremulous, there was a mist before the eyes, and there was frequent urination and excessive perspiration. The pulse was 90, the blood pressure: systolic, 116; diastolic, 80. The heart and lungs were negative, the hands cyanosed, the patella reflex was diminished, the pupils were dilated, there were photophobia and slight exophthalmos, he was dazed, and strength was less than development.

It should be noticed that the explosion of the first shell apparently did not affect him. This is often the case. A soldier may be blown up several times without feeling any ill effects, and then finally become completely incapacitated by a shell bursting near him. I have seen one patient who was knocked over five times by bursting shells within the period of fifteen minutes. A man is not always overcome at the time of an explosion of a shell near him; he may carry on his duties for several days before he finds it necessary to report sick, or he may not report sick until his condition is noticed by one of his officers, who orders him to see the medical officer.

Case 3 (No. 13582).—An infantryman, aged 32, whose civil occupation was that of a farmer, who had been in the army three years, and in France nineteen months, had never been seriously ill in his life, and did not know what it was to feel nervous. The family history was negative. He was married and had two children. He had been in five engagements with the enemy, over the top three times, and had been wounded twice. He had been decorated for bravery.

He was *selected to go on a raiding party* carrying hand grenades. During this expedition a shell exploded near him, and he was partially buried. He returned to the trenches and awoke the next morning feeling queer, and found that he was weak and dizzy. Twelve hours later he fainted, became unconscious, and was carried to the dressing station.

He felt very nervous, jumped at the least noise, was dizzy, urinated very frequently, had no appetite, could not sleep, was somewhat deaf, and could not see distinctly at times. The pulse was 90, the blood pressure: systolic, 120; diastolic, 80. The hands were cyanosed, the strength was less than development, the heart was slightly dilated but otherwise negative, there were fine tremors of the fingers, and the patient had a left-sided facial tic.

This was a very stubborn case; the patient remained in the hospital over seven weeks, improving very slowly.

It is by no means necessary that a man be actually knocked over by a shell before developing shell shock. The following history is fairly typical of many cases:

Case 4 (No. 96430).—A member of a labor company, aged 29, in civil life a mechanic, who had been in the army three years and in France sixteen months, said: "I grow very weak now; shell fire upsets me; I cannot sleep, and I have no appetite." His nerve had always been good. The family history was negative. He was married, and had three children. He had been wounded twice. The second time he was placed in a labor company, as he was not considered fit to be sent to a combatant unit. He had been in three engagements, and had been over the top twice. In 1916 a shell *fell* near him but it did not bother him.

He was with a party bringing up rations. The road was being shelled; shells were bursting all around him, *but he* was not blown over by any of them. When he returned to the camp he felt very queer, he began to tremble, and *then lost* consciousness for a few hours.

He was now suffering with a headache, he was very dizzy and weak, both legs ached, he urinated very frequently, his eyes ached, he slept very badly, his hands and feet felt cold, and he perspired excessively. The pulse was 118, the heart dilated, there was a functional cardiac murmur, the lungs were negative, there was exophthalmos, the hands were cyanosed, and there were tremors of the fingers, tongue and eyelids. The reflexes were lively, the pupils dilated and reacted to light slowly, the strength was less than the development, there was a positive Romberg sign, he walked on a wide base, he would fall down on turning around quickly, and he was dazed.

Quite a few men admitted into the hospital have had shell shock previously; some are recurrences and in others the patients are suffering from a second shock. Approximately 25 per cent. of the patients that I have examined during the last few months have suffered from shell shock previously. The following is the history of a soldier who had three distinct shocks:

Case 5 (No. 5557).—A tunneller, aged 26, *in civil life* a contractor, who had been in the army seventeen *months*, and in France nine months, reported: "I have been shell-shocked again." The first shell shock occurred in 1916, and the second in February, 1917. He said he had recovered fully from both. Previous to joining the army his nerve had been good. He was married. He took an active part in all forms of sport. His mother was insane.

He was in camp when the enemy flew over dropping bombs, and while he was running to shelter a bomb fell near him and he was knocked over. He felt very weak and was carried to the medical officer. He was now suffering from a very bad occipital headache, he did not sleep well at night, but got a little rest in the daytime. If he did go to sleep at night, he was apt to wake up walking around in his sleep. He had diarrhea and had been so affected each time that he had shell shock; he was dizzy and weak, urinated very frequently, perspired excessively, and at times his vision became poor. The pulse was 128, the heart dilated, the hands were cyanosed, the strength was less than development, the reflexes were normal, the pupils normal, the eyes prominent, the skin very rough, the hair coarse, he stammered, the fingers and forearms were very long, and there were fine tremors of the fingers, tongue and facial muscles.

It is sometimes the case that a man attempts to run away from what appears to be a dangerous position and goes into one that is more dangerous, as was the case in the preceding history. I know of one officer who had suffered from shell shock previously but had recovered and was on duty in a hospital, who ran out into the country one night to escape the aeroplanes that were immediately over his hospital. While passing through a village 5 kilometers away the planes dropped bombs near him. He developed a severe case of shell shock and was carried to the base, and here again the enemy bombed the town. He was then taken to the United Kingdom and arrived there a few hours before bombs were dropped.

A soldier often recovers from shell shock, returns to duty and renders valuable service to his country. The following is an example of such a case:

Case 6 (No. 7490).—A sergeant and pilot in the Royal Flying Corps, aged 20, whose civil occupation had been that of office boy, and who had been in the army two years, and in France, seventeen months, had suffered from shell shock twelve months before. It was so severe that he was sent to England for two months. He had fully recovered when he returned to France. He was never nervous before he entered the army. The family history was negative. He was very fond of sports. He had been a pilot since February, 1917. During this time he had been officially given the credit for bringing to the ground nine enemy aeroplanes.

In July, 1917, he was over the line doing patrol duty when his squadron was attacked by the enemy, he was cut off from the others, three planes attacked him, his observer was killed, and he came down 12,000 feet with his machine not under control. A few hundred feet above the ground he managed to gain control of his machine and effected a landing behind the British line.

He was now very weak, was unable to walk, could not even stand alone, the muscles of his face, neck, arms and thighs were constantly twitching, he had a very severe headache, his eyes ached, he felt very dizzy, and he was constantly living through the fight in his memory. The pulse was 70, the blood pressure: systolic, 110; diastolic, 70. The heart was dilated, the deep reflexes exaggerated, the pupils dilated and reaction sluggish, the strength less than development, and he was apprehensive.

This has proved to be a very stubborn case. The man has been in the hospital over nine weeks and he is improving very slowly. As I review the case histories that I have taken, I feel quite sure that those patients who have suffered from shell shock previously do not recover as a rule as rapidly as those that have had no previous attack.

It has been said that shell shock does not occur among the wounded. This, I am sure, is a mistake, but I believe that a severe case is comparatively rare among the wounded, although I have often seen wounded men in the hospitals suffering with mild forms of it.

There is yet another form of this condition which I myself have not seen, but which has been described by medical officers who are with battalions at the front. They say that death may be caused instantaneously by a shell bursting near a man, although most careful examination fails to show any cause for his death.

SYMPTOMS

I wish to emphasize the fact that shell shock is not a new disease to be added to the long list already puzzling the psychiatrists and neurologists. There is not a single new symptom to distinguish this malady, and it is certainly true that a similar complex of symptoms is frequently found in civil life. The disorder is peculiar in the acuteness of the symptoms and in the nature of the conditions giving rise to them. The war has enabled us to see examples of almost all varieties of hysterical manifestations, such as a special hospital in times of peace would only be able to exhibit in the course of years.

I have analyzed a hundred case histories in an attempt to discover the relative frequency of the symptoms, with the results given in the accompanying table.

RELATIVE FREQUENCY OF SYMPTOMS

Symptom	Percentage	Symptom	Percentage
Headache	85	Tinnitus	14
Tremors	70	Apprehension	14
Insomnia	62	Memory defect	14
Vertigo	55	Pupils dilated	12
Debility	44	Depression	12
Period of unconsciousness	41	Mutism	11
Cyanosis	35	Precordial pain	11
Hyperhidrosis	32	Stammering	10
Backache	30	Dyspnea	9
Heart dilated	29	Deafness	9
Reflexes exaggerated	28	Diarrhea	8
Tachycardia	26	Constipation	10
Appetite poor	24	Photophobia	6
Frequent urination	23	Tic	4
Eyes prominent	20	Spasticity	3
Nausea	16	Confusion	4

Besides the more common symptoms, there may be found areas of anesthesia or hyperesthesia, hysterical contractures, amblyopia, astasia abasia, hallucinations of sight or hearing, twilight states, hysterical convulsions, autopsychic amnesia, palpitation, and a tendency toward day dreaming.

These patients very often exhibit a marked impulse to flight; while they are being examined they may attempt to run away. If guns are fired in the vicinity of the hospital, or if the enemy's aeroplanes are in the neighborhood, many of them will become greatly excited. Following this excitement their symptoms are worse. After and during a bombardment, the sounds of which are heard in the distance, and although they realize that they are safe, nearly all of them complain that their headaches are much worse. They are easily startled and will jump at the least unexpected sound.

These individuals are very emotional; they might be described as being childish. They wish to be sympathized with, and very often if they are given the least opportunity, they will become lacrimose. They themselves are often at a loss to understand their condition and fear that they are going insane, and it is in such cases that the intelligent explanation of the medical officer is of great assistance.

Headache is probably the most constant symptom. It may be located over the frontal, temporal or occipital regions, but the last is the most constant and the most troublesome. A man often complains that his head is worse when he is in a recumbent position, and it is also usually worse at night than during the day.

Insomnia is quite common. The patient may be able to sleep during the day but is unable to do so at night, although he will usually fall asleep near dawn. A sleepless night tends to make the other symptoms worse.

The cyanosis of the hands is quite noticeable. Frequently in a severe case a man's hands and forearms will be a dark purplish blue, the color resembling that seen in Raynaud's disease. This cyanosis may develop several days after the patient's admission to the hospital, and is worse in the morning than later in the day.

About one fourth of the patients suffer with tachycardia. When they are admitted to the hospital their pulse rate may or may not be rapid; but under favorable conditions, such as exercise or excitement, it will become so. Some patients are admitted who have a very slow pulse; as they improve, their pulse may become normal, or frequently after they have rested a few hours a tachycardia will develop in place of the bradycardia.

BLOOD PRESSURE

With a view of ascertaining the blood pressure, 200 patients were examined; in all, over 800 observations were recorded on these patients. Some of these patients were only passing through the hospital, so that it was possible to take the blood pressure once, while others remained six weeks and the pressure of some of these was taken on ten different occasions. Usually the observations were made under as nearly the same conditions as possible, three or four days elapsing between examinations. A record was kept of the pulse rate at the time of each examination. In deciding if the pressure was raised, the age and physical condition of the patient were considered. A pulse of a hundred or more was usually considered rapid, and a systolic pressure of 140 or greater was considered raised, although in each case an effort was made to ascertain if the physical status of the individual justified his blood pressure.

The patients were classified according to the severity of their symptoms on admission as, A, exceptionally severe; B, severe; C, moderately severe, and D, mild.

Out of sixteen exceptionally severe cases, in twelve there was a high blood pressure and a rapid pulse, in three a normal pressure and pulse, and in one a blood pressure of 110 systolic and 68 diastolic, and a pulse rate of 52. The average pressure and pulse rate for the group was: systolic, 158; diastolic, 99, pulse pressure, 59, and pulse rate, 127.

In a group of twenty-nine severe cases, in twenty-two there was a blood pressure above normal, and in nineteen of these a rapid pulse. The average for the group was: systolic, 144; diastolic, 85; pulse pressure, 59, and pulse rate, 90.

There were sixty-six cases classified as moderately severe; in forty-eight of these the blood pressure was raised, and in twenty-eight there was a rapid pulse. The average for this group was: systolic, 135; diastolic, 88; pulse pressure, 47, and pulse rate, 90.

There were ninety-nine mild cases; in twenty-nine of these the blood pressure was raised, and in fourteen there was a rapid pulse. The average for the group was: systolic, 125; diastolic, 81; pulse pressure, 49, and pulse rate, 85.

It was difficult to draw any reliable conclusions from these observations, other than to say that the blood pressure and pulse rate in the severe cases were usually higher than in the mild cases; that there was a noticeable vasomotor instability in most of the cases; that as the condition of the patient improved, the blood pressure and pulse rate usually fell, and that the blood pressure was more persistently high than was the pulse rapid. It was noticed that the milder the case the quicker the blood pressure fell, and that convalescence took longest in those cases in which the blood pressure was persistently high. However, there were severe cases in which blood pressures and pulse rates were never above normal.

The effect of fright on the symptoms was very noticeable. The following is an example:

Case 7 (No. 68974).—A patient, aged 26, on admission, Aug. 12, 1917, could not walk or speak. The blood pressure was: systolic, 160; diastolic, 100; the pulse rate, 140. August 13, his condition was improved; the blood pressure was: systolic, 156; diastolic, 100; the pulse, 140. August 14, he had recovered the use of his voice and of his legs; the blood pressure was: systolic, 150; diastolic, 100; the pulse rate, 120.

August 21, six hours after an air raid, he was too weak to walk, and he stammered when he talked; the systolic pressure was 180, diastolic, 100, and pulse rate, 170. The blood pressure and pulse remained persistently high after this, and he was finally transferred to the base.

SYPHILIS

At one time it seemed desirable to know if syphilis played any part in producing the war neuroses. Therefore a Wassermann test was made in fifty consecutive cases of shell shock seen at the hospital. Seven cases out of fifty, or 14 per cent., gave a positive reaction. The spinal fluid was positive in three of these cases, although there were no symptoms suggestive of cerebrospinal syphilis.

This percentage of positive serums and spinal fluids is probably higher than is usually found among civilians, but the findings would not justify the conclusion that syphilis plays a part in causing shell shock.

TREATMENT

The treatment outlined here is simply a description of the methods of handling these patients in the two hospitals in which I was stationed. However, I believe that they are the methods in general use.

The patients are admitted, bathed and sent to the receiving ward. They are then examined and assigned to other wards; this has been always done within eighteen hours after admission to the hospital. At the time of the examination the following form is filled out:

Date. Name. Age. Civil occupation. Occupation in Army. Service in Army. Service in France. Adaptability to service. Family history (briefly).

Personal History: Education. Illnesses. Married or single. Active participation in sports. (Attempt to form some idea of the individual's personality.)

Previous Strain: Decoration for bravery, participation in raids, wounds, effect of shell fire, comrades recently killed, trouble at home.

Shell Shock: A complete story of what happened to him, where he was, what he was doing, and when it was. This is very important, for these facts are sent to his commanding officer for verification.

Symptoms: Headache, backache, weakness. Dizziness, dyspnea; nervous tremors, spasmodic movements, etc.

Physical Examination: This must be carefully made, for it is often necessary for the medical officer to state definitely whether or not the man is malingering.

Summary as to the severity of the case.

Treatment.

The patients are assigned to wards according to the severity of their condition. Cases of the same kind are grouped together, with the exception of the stammerers.

Military discipline is never relaxed for an instant in a shell shock hospital. The patients are not allowed to leave the grounds without a pass. These men are seen each day by a medical officer who makes a note on their record of their condition, prescribes the necessary treatment, and disposes of them as their condition justifies it.

Drugs are of very little use in treating this condition. Barbital (veronal) is sometimes given for insomnia. Acetylsalicylic acid and also phenacetin are given for the headache. Bromids may quiet the patient for a while, but from my experience I do not believe that they are of much value. Digitalis appears to have very little effect on the pulse rate.

In the acute cases, several hours in a hot bath seems to be more beneficial than almost anything else. A man who says he has not slept for several nights will relax and go to sleep while in the bath, and probably sleep soundly for eighteen hours afterward, usually awakening much improved. The hot bath is especially good in the cases of mild hallucination and for those markedly apprehensive patients who lie curled up in a ball under the cover, as well as those whose thigh, leg and back muscles are spastic.

The patients should be reassured, the nature of their condition should be explained to them, and the medical officer should do everything possible to secure and keep their confidence, for many of these men remind one of children who must be taught to walk, to talk, and to adjust themselves to their environment.

Practically the same methods are employed as in civil practice in teaching the stammerers to talk. They are taught to breathe properly, to pronounce consonants and vowels, and finally to repeat simple sentences.

I have not seen a shell shock mute who failed to recover his speech; but the longer he has been mute, the more difficult it is to get him to talk. It is important that, once one attempts to make a man talk, one should not desist from the effort until one succeeds; otherwise the patient will become confirmed in his opinion that he cannot talk. The quickest and most effective method, though it may appear brutal, is to stimulate the patient with a faradic current, rapidly increasing its intensity, having explained to the patient beforehand that there is nothing the matter with his voice, that he can talk, and that the strength of the current is going to be increased until he does talk. As the current becomes stronger the man will begin to squirm and will either immediately recover his voice or will make some sound, a long "Oh!" being the most frequent. In the latter case he is told that if he can make any sound at all he can talk; and the stimulation is continued until he does talk. This method is very effective and will work when all others fail, but it is open to the criticism of being brutal.

Another very successful method is to instruct the man to cough; if he cannot cough, his pharynx is tickled and he is made to cough. Then he is instructed to cough out an "ah," then "a," then "oh." He can usually then be made to pronounce these sounds without coughing. Then with a little encouragement he will repeat the alphabet, then simple words like "mama" and "papa," and so on until he can talk; but this is often a very long and difficult process to carry out. Hypnotism has been advocated, and so has the anesthetizing of the patient to the stage of excitement. Both are fairly successful.

I have seen hypnotism used in treating the symptoms of these patients with more or less success, but I do not believe that the claims of the advocates of hypnotism are justified.

A patient who says that he cannot walk is made to get out of bed and take the hands of the physician, who teaches him to walk in much the same way that a baby is taught.

Those patients who are not recovering from their hysterical symptoms are frequently stimulated with the faradic current, for it is undoubtedly true that many of these patients cannot see the need of hurrying their recovery, when they realize that as soon as they are well they will be returned to the front.

As soon as the patient is strong enough he is made to take physical drill, and as his condition improves, the exercises are made more difficult. They are also sent on long route marches daily. Besides this exercise they are encouraged to play cricket, golf, tennis, football, to swim and to take part in the track sports. Other amusements are furnished in the form of concerts, cinema shows and reading rooms.

As the patient's condition begins to improve, a long, confidential talk with the medical officer will often do much to hasten recovery.

DISPOSITION OF PATIENTS

If it is decided that a man will need careful treatment for several months, he is usually sent to England; otherwise he remains in France.

As the patient's condition improves and he becomes strong enough to leave the hospital, he is sent to a special convalescent camp, where he remains for several weeks before returning to his unit.

In some of the mild cases the men are practically well in a few days, and are returned to their units forthwith.

A man who has had several recurrences is usually unfit for the line, and he is often given work to do at the base.

It has been found beneficial to send patients out on farms to work rather than to convalescent camps. A man is in better condition to return to his unit after a month on a farm than after the same length of time spent in a convalescent depot.

Review of Public Health Work.—The year book of the Indiana State Health Department for 1917 contains a review by the secretary, Dr. J. N. Hurty, of public health work since the passage of the first health law in 1881. Efforts to establish a state board of health and laws under which it should operate were begun in 1855 in the Indiana State Medical Association, and it is to the organization that Dr. Hurty gives credit for all subsequent legislation. The efforts in 1855 failed, and not until 1875 was a committee appointed on state board of health. This committee drafted a bill which was introduced but failed in the legislature of 1875, and it was only in 1881 that the first law was passed and the board created. The latter made its first report in 1882. The law was amended in 1891 and again in 1909, and the state now has a board and a set of health laws and a health organization that is in the front rank among all the states. Among the important pieces of health legislation now on the statute books are a quarantine law, passed in 1903; a pure food and drug law, 1907, amended in 1911; a law for the prevention of infant blindness, 1911; laws enacted in 1913 relating to vital statistics, sanitary schoolhouses, public water supply, clean milk cans, public playgrounds, establishment of sanitary districts, housing plans, false advertisement law, schoolhouse recreation centers, and child neglect, and amended in 1915; also, among many others, an antituberculosis law passed in 1915.

VOLUNTARY REGULATION OF THE HEART BEAT

The frequency of the heart beat, which expresses itself in the pulse rate, is one of the various vital phenomena over which conscious control is not ordinarily exercised. There may be marked differences in the pulse rate found in different individuals without their having any pathologic significance attached to them, although the newer studies in nutrition, notably those of F. G. Benedict at the Boston Nutrition Laboratory of the Carnegie Institution of Washington, have tended to show a surprising parallelism between pulse rate and the intensity of metabolism. It is well known that the heart beat is quickened by warmth and diminished by cold applied to the surface of the skin of the vagus. The act of swallowing causes a reflex increase in heart rate by inhibition of the tonic action.

The function of the nervous system in the control of the frequency of the heart beat is familiar to every student of medicine. He has seen the inhibitory effect of vagus stimulation, the abolition of the tonic influence of the vagus by injury to the nerve or destruction of its center, and the augmentor effect of stimulation of the accelerators of the heart. Such demonstrations are experimentally produced effects. There are, however, published records of thirteen persons who possessed the power to accelerate their heart beat at will, the earliest authentic account dating back to 1872.[1] The newest case, in the person of a skilled observer,[2] has been carefully studied with a view to ascertaining the nature of the mechanism of acceleration. The uncertainty regarding this has wavered between the possibility of a removal of vagal influences, or of a primary action through the accelerator nerves, as the explanation of the voluntary acceleration. In the instance of Favill it begins almost immediately after the subject has willed it to begin, and as soon as one second after the command is given by the observer. The acceleration does not reach its maximum at once, several beats occurring before the high mark is attained. The degree of acceleration is greater, the stronger the impulse and the fresher the condition of the subject. The greatest acceleration recalled was an instance in which the pulse rate rose from 104 to 200, this paroxysm lasting for thirty seconds. According to the subject, it seems impossible to describe the sensations attending the production of the acceleration any more than one can describe the conscious effort in voluntary movement of the arm. With the onset of the tachycardia there is a feeling of "fulness" or tingling over the whole body. A mild exhilaration follows in a few seconds, and moderate fatigue results if the paroxysm is induced several times successively, or for any period longer than a very few seconds. The acceleration is dependent on a distinct effort of the will, and the strain is as tiring as that produced by holding up a heavy weight; it is not a succession of efforts, but one that is continuous. Distinct relief is felt with the cessation of the acceleration.

The physiologic investigation of this subject showed that with the onset of the acceleration there is no apparent change in the situation of the "pacemaker"—that collection of peculiar muscular tissue in intimate relation to the nerves entering the heart, and from which the normal beat is now believed to arise. The changes in the electrocardiographic deflections during the acceleration are those that are known to occur when the sympathetic nerves are stimulated experimentally. The ability to accelerate the rate of the heart beats persists after the suppression of vagus action by atropin. The evidence available suggests that the voluntary increase of the heart rate is the result, in great part at least, of the action of the accelerator nerve mechanism, and that it is not due solely or chiefly to the withdrawal of vagal action.

MEDICAL PRACTICES IN SOME PHILIPPINE PROVINCES

The history of medicine shows that at practically all stages of civilization, and among the most diverse types of races, man gradually learned by experience to appreciate the effects of certain agencies for good or harm in relation to his own person. In his story of the growth of medicine from its earliest period, Buck[1] has portrayed how the powers of observation and the reasoning faculty presumably have been applied to the avoidance of bodily dangers and the relief from physical suffering. Buck suggests how man "gradually learned that cold, under certain circumstances, is competent to produce pain in the chest, shortness of breath, active secretion of mucus, etc., and his instinct led him, when he became affected in this manner, to crave the local application of heat as a means of affording relief from these distressing symptoms. Again, when he used certain plants as food he could scarcely fail to note the facts that some of them produced a refreshing or cooling effect, that others induced a sensation of warmth, and finally that others still, by reason of their poisonous properties, did actual harm. Sooner or later, such phenomena as nausea, vomiting and diarrhea would also be attributed by him to their true causes. In due course of time his friends and neighbors, having made similar observations and having tried various remedial procedures for the relief of their bodily ills, would come together and compare with him their several experiences; and so eventually the fact would be brought out that the particular method adopted by one of their number for the relief of certain symptoms had proved more effective than any of the others. Thus gradually this isolated community or tribe of men must have learned how to treat, more or less successfully, the simpler ills to which they were liable."

---

[1] Buck, A. H.: The Growth of Medicine from the Earliest Times to About 1800, New Haven, 1917.

To us living in what we delight to designate an age of enlightened progress, the story of "trial and error" has a primitive ring. We scarcely realize, until we are brought face to face with the actual experiences, that even today much if not most of the oriental medical art or practice still partakes of the pristine character. Whether it be in India or China, folklore and superstition are mingled with tested procedures in the healing arts. Exhortation of spirits, incantations, acupuncture and cauterization find a place only in a system in which modern pathology is unknown. Yet in our own provinces in the Far East we may still find elaborate instances of a sort of medical practice that can vie in primitiveness with the procedures of centuries ago.

One need only read the first of a series of reports on the local medical practices in the Department of Mindanao and Sulu, Philippine Islands, to verify this statement.[2] The customs in Cotabato, the largest province in area in the islands, are said to be characteristic of the practice of the Mohammedan (Moro) population. Disease is attributed to a variety of causes, such as poison, hunger, wind, sun, unfulfilled customs, promises or oaths, and animalcules; but the most frequently alleged causes are malignant spirits. To avert the influence of the unkind or harmful incantations of another, the Moros place under the mattress of their beds a goat skin with various colors, and offer a prayer before going to bed as well as after leaving it. The mode of establishing the prognosis in disease seems decidedly simpler than the elaborate information that our own judgment of the probable outcome demands. It is found by opening the Koran and determining the hour, day, month and tide in which the disease began. A disease that begins with high tide is liable to be serious, whereas one that begins with low tide is more likely to be mild. Thus there is something lunar, if not lunatic, in the prognosis.

The treatment of diseases among these people, according to Gomez, is a mixture of religion, superstition, and medicine concocted by the medicine man from plant forms. In addition to this his therapeutics include prayers and cabalistic signs. Amulets are freely used The prescriptions for curative potions are too elaborate to be repeated here. The directions for the management of malaria will suffice as an illustration Thirty leaves of yerba buena having the letter *alip* written on them are used to rub the body. Furthermore, bamboo shoots are to be cooked in water, honey is to be added, and the mixture drunk. Gomez states that no surgery is performed by the tribes he has studied. They have no idea of infection, and seem to regard pus as a natural secretion of a wound. An abscess is treated by means of hot water or fomentations of some sort; subsequently the point is opened and tobacco or fine shavings of coconut stalk are applied to drain the pus. The Maguindanaos understand, however, how to pull and medicate carious teeth. To the latter they apply ginger and salt heated together and placed while hot in the cavity. They can even put on crowns of gold and silver which silversmiths manufacture. The transmission of communicable diseases is favored by the ignorance of the people, their unhygienic surroundings, poor nutrition, personal habits and frequency of travel. Religious sanctions add further difficulties. Here, indeed, are problems that tax the ingenuity and patience of the modern sanitarian to the utmost.

INTESTINAL INTOXICATIONS IN INFANCY

If some semblance of an orderly and logical conception of the possible nature of the so-called intestinal intoxication, or diarrhea with toxic symptoms," in infants is beginning to arise out of the chaos of past uncertainties, we owe it largely to the more exact methods of recent clinical study. Phenomena suggesting toxicity and occurring in association with profound nutritional disorder in infants have long been recognized; but mere empiric observations, and routine measurements of pulse and temperature, casual inspection of stools, and manipulations of diet have not promoted any noteworthy advance in the understanding of a clinical entity. It is due to the persistent and often little appreciated efforts of a small group of investigators in the domain of pediatrics, notably in American laboratories, where successful methods have been so skilfully developed in the past few years, that substantial progress is being recorded.

If this statement needs to be justified, let us consider a few of the recent contributions with reference to their pertinence. In one of the latest experimental studies of intestinal intoxication, Schloss[1] has written:

---

[2] Gomez, L.: Mohammedan Medical Practices in Cotabato Province, Philippine Jour. Sc., (B), 1917, 12, 261.

> There is a close analogy between intestinal intoxication and uremia. Indeed, all of the evidence points directly to the fact that their nature is essentially the same. In uremia the kidney fails to fulfil its proper function, owing to an anatomic lesion. In intestinal intoxication the same result is brought about through loss of fluid. Waste products normally excreted by the kidneys are retained because there is insufficient water for diuresis.
>
> Similar to uremia, based on symptomatology, there are two groups of cases of intestinal intoxication. In one group convulsions, involuntary muscular movements, muscular twitching and coma are present. The onset is usually acute and the infant is not greatly emaciated. Diarrhea may be slight and is absent in some cases. Food or water is usually refused and is vomited if taken.
>
> In the second group the onset is less acute, but occurs following vomiting and diarrhea of some days' duration. Convulsions rarely occur and the infant is somnolent or semistuporous instead of comatose. Wasting is very marked and the patient presents the shrunken appearance which is so characteristic of great loss of fluid.

The negative water balance of the body and the consequent oliguria particularly found in children, in whom the losses of water through vomiting and diarrhea may be unexpectedly large, have received all too little attention because they were not accurately ascertained and thereupon adequately appreciated. Part of the new evidence consists in the now well established demonstration of a marked increase in the nonprotein nitrogen and urea of the blood in infants suffering from typical intestinal intoxication. At first thought one would naturally ascribe this to an impairment of renal function as the result of kidney lesions. Schloss is not inclined to accept such an explanation. In his judgment the character of the urine examined in such cases does not justify the assumption of severe anatomic lesions. That these are no longer to be regarded as the sole criteria of kidney malfunction in infancy is further supported by Howland and Marriott's[2] study of acidosis occurring with diarrhea. They, too, note that in severe diarrhea the urinary secretion may be markedly diminished even to the point of complete anuria, the kidney becoming functionally more or less inactive, even though no organic changes may be present.

Aside from a definite kidney lesion, the most probable cause of the retention phenomena appears, as Schloss has argued, to lie in a depleted water supply of the body. In corroboration of this it is known that water is a most effective diuretic; and latterly it has been found that the proper administration of water is an efficacious method of combating some of the severe nutritional disorders of infants. In attempting to explain the deficient secretion of urine on a new basis, Schloss argues thus:

> The oliguria may be due to the fact that the dehydrated tissues hold as much water as possible so that none is available for the formation of urine. Other factors, dependent mainly on the loss of water, which may play a rôle are: (1) an increase in the concentration of blood colloids to such degree that their osmotic pressure is greater than the arterial pressure in the kidney; (2) a diminution in the total blood volume leading to decreased blood flow through the kidney.

What, then, is the significance of the acidosis that has been associated so clearly with such diarrheal disorders in infancy? Howland and Marriott[2] assert that it is not due to the presence of acetone bodies; nor has it been shown to be due to the loss of a base, that is, alkali depletion in the strict sense. Schloss agrees with them in the conclusion that the acidosis which is exhibited in intestinal intoxication is due to defective secretion, probably of acid phosphate, by the kidneys.

The improvement that occurs after the administration of sodium bicarbonate may, then, have a twofold explanation. In part it may be due to a direct correction of the acidosis by alkali; in part, furthermore, the associated intake of water may contribute to betterment. In any event, it seems quite rational to replace water lost in the consequence of the symptoms already referred to. The vomiting and diarrhea often prevent its administration by the conventional methods through either mouth or rectum. At Howland's suggestion, Blackfan and Maxcy[3] of the Johns Hopkins Hospital have tested the possibilities of intraperitoneal injections of saline solutions. They recognize the technical difficulties of any intravenous procedure; and the subcutaneous method is rejected as slow and unreliable in respect to the extent of actual absorption. The intraperitoneal procedure requires great care and strict aseptic precautions; but in the hands of skilled manipulators the results are reported to be highly satisfactory.

THE ORIGIN OF PROGRESSIVE MUSCULAR DYSTROPHY

Progressive muscular dystrophy must at present be classed among the relatively uncommon disorders of man. Despite a group of frequently described clinical symptoms, including dryness and abnormal pigmentation of the skin, brittleness of the hair, hypertrichosis, trophic changes in the nails, unusual distribution of the subcutaneous fat, and both hypertrophy and underdevelopment of the genitalia, in addition to the muscular phenomena, the cause of these manifestations has not yet been unraveled. At one time it was customary to assign the etiology of muscular dystrophy to a defect in the nervous mechanism through the innervation of which the contractile tissue is set and maintained in activity. Neither a purely nervous origin nor a causal factor limited to the muscle structure itself can be defended as affording a complete explanation of the disease. The accompaniments of what might be interpreted as defects of either the muscular or the nervous apparatus of the body are too varied and significant to permit so simple a statement of the pathology of muscular dystrophy.

[3] Blackfan, K. D., and Maxcy, K. F.: The Intraperitoneal Injection of Saline Solution, Am. Jour. Dis. Child., January, 1918, p. 19.

Quite independently, two groups of American investigators[1] have recently expressed the belief that muscular dystrophy may originate as a result of abnormal functioning on the part of endocrine organs. To substantiate this hypothesis, certain accurately ascertained facts have been marshaled. In the cases observed at the Montefiore Home and Hospital, New York, Janney, Goodhart and Isaacson have reported the following disturbances: marked decrease in the preformed creatinin in the urine, abnormal presence of creatin in the urine, low values of creatinin in the blood, normal amount of creatin in the blood, hypoglycemia and delayed glucose utilization. McCrudden of the Robert B. Brigham Hospital, Boston, has emphasized these features: low blood sugar, and, following suitable treatment, a rise in blood sugar accompanied by an increase in strength; creatinuria; low cholesterol content of the blood — three independent testimonies, as he says, of disturbed carbohydrate metabolism.[2]

It is asserted, with not a little justice, that practically all the clinical symptoms and metabolic signs already referred to have been observed in well known hypofunctional conditions of the ductless glands. The lowered content of sugar in the blood has, indeed, repeatedly been associated with such conditions, for example, in the hypoglycemia of dyspituitarism.[3] One might reasonably ask whether the hypoglycemia is not a consequence of the disuse of muscles and a consequent "lessened requirement for carbohydrate." From studies of McCrudden and Sargent[2] the answer seems to be in the negative; for in the somewhat similar condition of progressive muscular atrophy the blood sugar was found to be normal. The New York investigators are further inclined to charge the excretion of creatin, always an unusual metabolic result in the adult, to an insufficient supply of carbohydrate in the muscles. As we have occasionally pointed out, however, the interrelations of creatin-creatinin metabolism and carbohydrate transformations in the body are as yet by no means clear.[4]

The hypothesis as portrayed by McCrudden is suggestive in many ways. The facts, he concludes, indicate that the *myasthenia* of progressive muscular dystrophy is due to hypoglycemia; that the hypoglycemia and fatty infiltration are due to impaired glycogenesis, the carbohydrate of the food being probably changed largely to fat instead of glycogen; and that this impaired glycogenesis is the result of suprarenal or other endocrine disease. Realizing the complexity of the manifestations, and appealing to analogies in other diseases that involve growth, adiposity or defective bone formation, Janney, Goodhart and Isaacson go even further. We must face the possibility, they declare, of muscular dystrophy and perhaps other so-called primary myopathies being in reality merely syndromes caused by deficient function, not of one but of various endocrine organs separately or coincidently affected.

Current Comment

THE NEED OF MEDICAL OFFICERS FOR THE ARMY AND NAVY

As one reads the reports of the war conference of the secretaries of the state medical societies held in Chicago recently and published in The Journal beginning with last week's issue, it becomes quite apparent that one reason why physicians are not volunteering for the Medical Reserve Corps is a lack of information. This includes a lack of information relative not only to the actual needs of the government services, but also on matters relating to the individual himself. This is borne out by the hundreds of letters that are being received at The Journal office. The writers ask for information regarding the needs of the service, the pay of officers, the cost of equipment, the duties, the arrangements for the care of dependents, the disposition of leases, insurance — in fact, on almost every subject. A great many have even detailed all the personal facts concerning themselves and have asked The Journal to make the decision as to whether they should enter the service. The Journal is not able to make the decision, but it has been trying, both by letters and in the columns of The Journal, to supply the information asked for. As to the needs: The fact is that the Surgeon-General of the Army is calling for 5,000 more volunteers for the Medical Reserve Corps and that the Surgeon-General of the Navy is asking for 100 volunteers a month for that service, or until he has another 1,000 medical reserve officers. The fact that officers of the Medical Reserve Corps in some communities have not yet been ordered to active duty has caused other physicians not yet in the service to believe that there is no need for more medical officers. This impression is erroneous. While it is true that the present and immediate needs are supplied, there is need for an adequate reserve and that need is urgent. It is for this reserve that the Surgeon-General is now appealing to the profession. Let every reader ask himself the question: Is it *my duty* to volunteer? And then let him answer it honestly.

A MILITARY MEDICAL SURVEY

The first step in the campaign to secure additional Medical Reserve Officers is to ascertain the conditions in the various parts of the country, i. e., to know the proportion of physicians to the population, the number of physicians in a community who are available so far as age is concerned, the number who are already in the service, and the needs of the civilian population. When these and similar facts are known, there will be dependable information available for systematic and logical procedure in securing the number of physicians needed to supply the demand. Such a survey is in course of preparation by the Association; it will give the number of physicians in every county and large city in each state, the number of physicians under 55 and under 45 years of age, and the number and names of those who are now commissioned. It was hoped that it would be ready for publication before this time. However, a survey such as is in preparation is a difficult and tedious task; it requires not only the compilation of a vast amount of data, but also much checking and verification. This survey will appear in The Journal for May 25 or June 1. It will show what each county has done, and will undoubtedly reveal that many communities have supplied more than their quota, while many have not done their share. Meanwhile, it is obviously unnecessary for any one who desires to volunteer for the Medical Reserve Corps to wait for the publication of this survey. Application blanks, lists of examining boards and information will be sent on request.

INFORMATION REGARDING MILITARY MEDICAL SERVICE

Many physicians are hesitating about applying for a commission in the Medical Reserve Corps; they are anxious regarding the care of their families. Even the pay of a lieutenant in the Medical Reserve Corps, $2,000 per year, with commutation, if he has dependents, of from $400 to $600 per year, while not sufficient to support some families in the style to which they have become accustomed, at the same time is far from a starvation income. It should be distinctly attractive to the physician without dependents. As The Journal stated two weeks ago, the physician who volunteers for the Medical Reserve Corps today is volunteering under different conditions than existed a year ago when our country entered the war. Recent constructive legislation has removed many of the obstacles that confronted the physician at that time. Of course, while commenting on the material aspects of the matter, we realize that patriotism and a desire to help win this war will certainly overweigh what sacrifices may have to be made in this regard. Application blanks, a list of examining boards and information will be sent on request.

Recognizing the Rights of Children.—The higher a nation stands on the stage of culture and civilization, the stronger is its race consciousness, the more clear its recognition of its duty to future generations, and the more pronounced and emphatic its assertion of the rights of children as members of society.—*Public Health* (Mich.).

WAR CONFERENCE OF SECRETARIES OF THE CONSTITUENT STATE ASSOCIATIONS OF THE AMERICAN MEDICAL ASSOCIATION

Held at the Headquarters of the American Medical Association, April 30, 1918

(*Continued from page 1306*)

Below are continued the reports of the state secretaries at the war conference held in Chicago, April 30. The reports of the states in alphabetical order from Alabama to Missouri appeared last week:

MISSOURI

Dr. E. J. Goodwin, Missouri, said: Missouri makes it unanimous so far as inability to accomplish anything harmoniously or coordinately, so far as definiteness of information is concerned. In spite of such difficulties, however, we have obtained our quota of applicants. I do not think they have all been commissioned. In St. Louis some work is being done, but not by the state organization. There has been no work conducted by the state organization in any part of the state. The state secretary has endeavored to include the state association in his work, but has never been able to get out the work through the state association, because the information given out from Washington is often inaccurate and has to be corrected; so we ceased giving it out. In Jackson County there has recently been a successful campaign conducted under Dr. McAlester, and that was done through the cooperation of the Jackson County Medical Society. It is well for us to know how it has been done in all the states. I should like to hear from all the states what the past has been, and then we can judge as to what the future work may be and how we can go about it.

When the announcement came from the Surgeon-General that he desired and was anxiously hoping to have the cooperation and assistance of the American Medical Association and the state and county societies, a great sigh of relief went up from more than one man in the state of Missouri, because we believe that anything that comes from the American Medical Association has been well digested and has the advantage of knowledge of conditions in every part of the country; and a knowledge of the individual characteristics of pretty nearly every doctor in the country, and what is done will be done with justice to all. And this is what we want to formulate, so that in future the things to be done by the medical profession will be done with accuracy and justice to all of us.

The chairman introduced Dr. A. W. McAlester of Kansas City, formerly secretary of the Missouri State Medical Association, who said: We have been fortunate in having Dr. Jabez N. Jackson a member of our advisory board. Dr. Binney was the chairman of our local council of physicians, but was called into service at a base hospital. I was connected with the aviation service and he asked me to take over the work. He told us that he wanted everything the government had asked of physicians. We prepared a questionnaire which is practically the same as the blank the government sends out to applicants for the Medical Reserve Corps. We added to that inquiries about the number of dependents, the amount and conditions of personal indebtedness, whether any of his dependents had an income, whether there was income from other than professional sources, etc. We looked for authority for this, and found that the act of Aug. 20, 1916, gave the government the right through its Council to ask physicians these questions. That act is very much like the constitution of the American Medical Association. We can spread it out to cover almost any activity. We sent out notices published in The Journal, with the telegram from the Surgeon-General stating the need for 8,000 physicians, along with this questionnaire. We appointed a man in each ward who saw every man in his district, presented him with the list of interrogatories, and had these turned in in five days. And we have them. We are now prepared to tell you the status of every physician in Kansas City. We are in a position to draft them. What they are willing to do, we know. The town has been thoroughly cleaned up.

MONTANA

Dr. E. G. Balsam. Billings, said: I think there are too many committees doing the same work. If I should tell you all the committees of which I am secretary, I would tire you. As long as the American Medical Association is so well organized, there is no better body of men able to take care of this thing without friction, and do it in an efficient manner through the different state organizations, and they in turn through the county societies. We do not need any more committees. Each one of us in each county is able to do the work, and he is the man on whom we can depend, and our reports may be returned to the secretary of the American Medical Association. We have in Montana forty-seven counties, only sixteen of which are organized and thirteen thoroughly organized; so you can see what a proposition it is to handle the state of Montana. Our difficulty is how to get the physicians from the cities to enlist and to meet the men who are in the country places in their respective towns. We have one city in which fourteen men have enlisted, and since fourteen men have gone, ten men came in from the country to fill the positions these men occupied in the cities. We need these men in the country towns because there are counties in Montana with an area of 5,000 square miles without a physician. How can we best get a man there and keep him busy and satisfied? We must arrange to keep men in these places. At our last annual meeting, through the efforts of the Council of National Defense and through the state organization working continually, we passed a resolution unanimously favoring conscription or the selective draft of physicians in our state. Every man of the 125 in our meeting rose to his feet when the resolution was passed.

NEBRASKA

Dr. Joseph M. Aikin, Omaha, said: It is fruitless for me to state the situation in Nebraska other than to refer to the remarks of the previous speaker with reference to conditions in his state, and also to what was said by the secretary of the Michigan State Medical Association. In Nebraska we have only fifty-three or fifty-four counties out of possibly ninety-four or ninety-three that are organized, and the great question asked of the state secretary by medical men is, What am I to do? When shall I be called after I have my commission? Another question asked is, Why do you ask for another 5,000 physicians plus 2,000 when a number of the men in Nebraska commissioned are not being called? We have been up in the air between the work of our state association and the taking of orders from the Council of National Defense at Washington and the Nebraska State Medical Society Council to know just how we should work with a multiplicity of committees. Our State Council of Medical Defense, Medical Section, has done practically nothing in Nebraska. I have not known just why. The consensus of opinion in Nebraska is, that now is an opportune time for the American Medical Association to take its stand in a cause in which our services are so much in demand, in order that the work to be done by medical men shall be intelligently done and propagated through the office of the American Medical Association in Chicago. We feel that as a result of this conference between the committee from the Board of Trustees of the American Medical Association and the state secretaries, whatever resolution is introduced here and adopted as the consensus of opinion of the best body of medical men that can be gathered together in the United States or in the world should be handed to the state secretaries of the United States as the plan of action for medical associations. Let each secretary take the matter up with his county secretary, adopting their own line of procedure, going right back to the unit of our organization, the county society.

NEVADA

Dr. M. A. Robison, Reno, said: There has really been nothing done in Nevada on an organized basis. The medical defense had one meeting and organized; we had another meeting and there were only three present. That is all that has been done in an organized way. Dr. Sinclair was commissioned and has examined other volunteers throughout the state. He reports to me that he has examined thirty-two, and several of them have received their commissions, he thinks. I notice from the report of the secretary of the American Medical Association that there are twenty-nine who have been given commissions. A report I received two days ago states that there are nineteen in the active service. Our state is much like Arizona, only more so. I believe we should work for a change in the appointments and ranks, and that this thing should be put under the direction of one man. Have the secretary of the county society or let the secretary of the state association designate who will do it; get up the questionnaires and report to the American Medical Association and let a man be called before the committee and say, "We want you."

NEW HAMPSHIRE

Dr. D E. Sullivan, Concord, said: I attended a county meeting of our society last Friday, and at that meeting I found out where our state stood from the official bulletin at Washington. That thing demonstrated to me that a physician can belong to the parent society, be secretary of the state society and secretary of the state committee of national defense, as I am, and yet not be able to keep in touch with the men who are going into the service. The only information I have is what I pick up here and there. It is necessary that a secretary should know what men have gone into the service and those who have not. It is difficult by means of appeals to get some men to enter the service. They hear all kinds of reports of men being in camps, lounging about with nothing to do. I am satisfied that good results must come from direct personal appeals. With the American Medical Association at the head, it must be thoroughly and efficiently supplemented through the efforts of local men who come in close cooperation, hand to hand, with the men whom we need.

NEW JERSEY

Dr. Thomas N. Gray, East Orange, said: New Jersey has been gone over with a fine tooth comb to raise the quota established by the state through the efforts of the Council of National Defense, Medical Section, and the committee of the state society. The chairman of that committee is one of the vice presidents of the society, and the secretary of the state society is a member, so that there is no clash between local defense and state defense. They left me to plan out a line of procedure. In my office as secretary of the state committee I sent out questionnaires and circular letters. I have written questions to young practitioners and have made it my business to go into their offices to find out that the questionnaires I sent them were thrown into the waste paper basket, and I said, "What is the use, they do not read them." Let us devise some plan by which we can approach these men. We have divided the work in this way: I, as secretary of the state society, would appoint a meeting for the county society, and as secretary of the state committee of national defense, I would arrange meetings in private local societies where we would meet the men who are not members of the state society. In our state we have 1,750 members out of 3,000. We can reach in the county societies other men we could not reach in the local society. We have visited all county and local societies repeatedly with officers from the department at Washington. We had no trouble in the rural communities if there was one more man that could go. Our trouble was to get a number of men in the big cities. In addition to appealing to those men, we went out, each in our own counties, and did all we could by personal work. I have had conversations with 450 young men in the late twenties and early thirties who I know have not had and cannot have in the whole of their practices of a few years an income to exceed $1,500, and most of them not more than $700. It is our conviction that every man in New Jersey who is willing to give his services to the government has enlisted, and if we are to get any more men from New Jersey we will have to conscript them. I believe the only way to get the men will be sooner or later to conscript them. If the American Medical Association through its influence cannot induce them to join the service, then as secretary I will take off my coat and use a finer tooth comb; but I do not believe I shall be successful.

NEW MEXICO

Dr. R. E. McBride, Las Cruces, said: New Mexico occupies the same position as Arizona. Out of 440 and odd physicians in New Mexico, 40 per cent. are sick men, and another proportion of them are men who have gone there with some members of their family sick, some of them bedridden. According to the *Bulletin*, New Mexico has 210 members of county societies, and among that number there are 198 in good standing in the state society. Forty per cent. of them are either over age or sick, so that when it comes to the eligibles for military service, the figures do not quite give the exact condition of affairs. There are not over 125 men in the whole state of New Mexico who are fit for the work of the service. Out of those 125 there have been fifty-four commissioned, but they have not all accepted their commissions.

A MILITARY MEDICAL SURVEY

The first step in the campaign to secure additional Medical Reserve Officers is to ascertain the conditions in the various parts of the country, i. e., to know the proportion of physicians to the population, the number of physicians in a community who are available so far as age is concerned, the number who are already in the service, and the needs of the civilian population. When these and similar facts are known, there will be dependable information available for systematic and logical procedure in securing the number of physicians needed to supply the demand. Such a survey is in course of preparation by the Association; it will give the number of physicians in every county and large city in each state, the number of physicians under 55 and under 45 years of age, and the number and names of those who are now commissioned. It was hoped that it would be ready for publication before this time. However, a survey such as is in preparation is a difficult and tedious task; it requires not only the compilation of a vast amount of data, but also much checking and verification. This survey will appear in The Journal for May 25 or June 1. It will show what each county has done, and will undoubtedly reveal that many communities have supplied more than their quota, while many have not done their share. Meanwhile, it is obviously unnecessary for any one who desires to volunteer for the Medical Reserve Corps to wait for the publication of this survey. Application blanks, lists of examining boards and information will be sent on request.

INFORMATION REGARDING MILITARY MEDICAL SERVICE

Many physicians are hesitating about applying for a commission in the Medical Reserve Corps; they are anxious regarding the care of their families. Even the pay of a lieutenant in the Medical Reserve Corps, $2,000 per year, with commutation, if he has dependents, of from $400 to $600 per year, while not sufficient to support some families in the style to which they have become accustomed, at the same time is far from a starvation income. It should be distinctly attractive to the physician without dependents. As The Journal stated two weeks ago, the physician who volunteers for the Medical Reserve Corps today is volunteering under different conditions than existed a year ago when our country entered the war. Recent constructive legislation has removed many of the obstacles that confronted the physician at that time. Of course, while commenting on the material aspects of the matter, we realize that patriotism and a desire to help win this war will certainly overweigh what sacrifices may have to be made in this regard. Application blanks, a list of examining boards and information will be sent on request.

WAR CONFERENCE OF SECRETARIES OF THE CONSTITUENT STATE ASSOCIATIONS OF THE AMERICAN MEDICAL ASSOCIATION

Held at the Headquarters of the American Medical Association, April 30, 1918

(*Continued from page 1306*)

Below are continued the reports of the state secretaries at the war conference held in Chicago, April 30. The reports of the states in alphabetical order from Alabama to Missouri appeared last week:

MISSOURI

Dr. E. J. Goodwin, Missouri, said: Missouri makes it unanimous so far as inability to accomplish anything harmoniously or coordinately, so far as definiteness of information is concerned. In spite of such difficulties, however, we have obtained our quota of applicants. I do not think they have all been commissioned. In St. Louis some work is being done, but not by the state organization. There has been no work conducted by the state organization in any part of the state. The state secretary has endeavored to include the state association in his work, but has never been able to get out the work through the state association, because the information given out from Washington is often inaccurate and has to be corrected; so we ceased giving it out. In Jackson County there has recently been a successful campaign conducted under Dr. McAlester, and that was done through the cooperation of the Jackson County Medical Society. It is well for us to know how it has been done in all the states. I should like to hear from all the states what the past has been, and then we can judge as to what the future work may be and how we can go about it.

When the announcement came from the Surgeon-General that he desired and was anxiously hoping to have the cooperation and assistance of the American Medical Association and the state and county societies, a great sigh of relief went up from more than one man in the state of Missouri, because we believe that anything that comes from the American Medical Association has been well digested and has the advantage of knowledge of conditions in every part of the country; and a knowledge of the individual characteristics of pretty nearly every doctor in the country, and what is done will be done with justice to all. And this is what we want to formulate, so that in future the things to be done by the medical profession will be done with accuracy and justice to all of us.

The chairman introduced Dr. A. W. McAlester of Kansas City, formerly secretary of the Missouri State Medical Association, who said: We have been fortunate in having Dr. Jabez N. Jackson a member of our advisory board. Dr. Binney was the chairman of our local council of physicians, but was called into service at a base hospital. I was connected with the aviation service and he asked me to take over the work. He told us that he wanted everything the government had asked of physicians. We prepared a questionnaire which is practically the same as the blank the government sends out to applicants for the Medical Reserve Corps. We added to that inquiries about the number of dependents, the amount and conditions of personal indebtedness, whether any of his dependents had an income, whether there was income from other than professional sources, etc. We looked for authority for this, and found that the act of Aug. 20, 1916, gave the government the right through its Council to ask physicians these questions. That act is very much like the constitution of the American Medical Association. We can spread it out to cover almost any activity. We sent out notices published in The Journal, with the telegram from the Surgeon-General stating the need for 8,000 physicians, along with this questionnaire. We appointed a man in each ward who saw every man in his district, presented him with the list of interrogatories, and had these turned in in five days. And we have them. We are now prepared to tell you the status of every physician in Kansas City. We are in a position to draft them. What they are willing to do, we know. The town has been thoroughly cleaned up.

THE NEW MILITARY SERVICE BILL OF GREAT BRITAIN AND ITS RELATION TO THE MEDICAL PROFESSION

The question of the supply of medical officers for the British army has been one of tremendous seriousness. With a numerical strength of physicians approximately one fifth of that of this country and with a much larger army, the securing of a sufficient number of medical officers has been a severe drain on the profession. A new medical service bill fixes the age of compulsory military service at from 18 to 55, inclusive, subject to provisos as follows:

> (a) If it appears to His Majesty at any time that it is necessary so to do for the defence of the realm, His Majesty may, by order in Council, declare that the foregoing provisions shall, as respects men generally, or as respects any class of men, have effect, as from a date to be specified in the order, as if any age specified in the order not exceeding fifty six years were therein substituted for the age of fifty-one years; and
>
> (b) as respects any person being a duly qualified medical practitioner, the foregoing provisions shall have effect as if the age of fifty-six years were therein substituted for the age of fifty-one years.

Clause 2 of the act gives power to declare by proclamation that a national emergency has arisen and that any certificates of exemption to any class or body of men shall cease to have effect.

In an editorial the *British Medical Journal* reviews what has been done to secure medical officers for the British army:

THE BRITISH MEDICAL JOURNAL'S EDITORIAL

"The introduction of the new Military Service Bill and the special provision which it contains with regard to medical men makes it opportune briefly to recall the steps by which the present situation, so far as it specially affects the medical profession, has been brought about. The annual general meeting of the British Medical Association in Aberdeen had ended a few days before the outbreak of war, so that the association had no special machinery in existence for dealing with the emergency. The War Office immediately called up the medical officers of the Special Reserve, and the medical officers of the Territorial Force belonging to the combatant units were mobilized with those units. Medical officers *à la suite* of the Territorial general hospitals were mobilized as those hospitals were got ready. With the regulars and reemployed regular officers the total number of medical officers obtained from these sources was about 4,000, and nearly three fourths of them were withdrawn completely or in part from the civil profession. At the same time an appeal was made for volunteers, one of the terms being that the volunteer undertook to serve if required for at least twelve months, with the right then to relinquish his commission. The response to this appeal produced about 1,140 by the end of 1914, and about 2,700 by the end of 1915. The first step spontaneously taken by the organized body of the profession to meet the emergency disclosed by the German advance into Belgium and Lord Kitchener's appeal to the manhood of the country was taken at the instance of the late Dr. Hamilton of Hawick by the Scottish Committee of the British Medical Association. By September the Scottish Medical Service Emergency Committee, consisting of representatives of Scottish universities and medical corporations and the British Medical Association, had been formed. In England and Wales preliminary arrangements were undertaken by committees of the British Medical Association, which reported to the annual meeting in 1915, when the Central Medical War Committee was constituted. It was instructed 'to organize the medical profession in such a way as will enable the government to use every medical practitioner fit to serve the country in such a manner as to turn his qualifications to the best possible use, and to deal with all matters affecting the medical profession arising in connection with the war.' Local Medical War Committees were set up throughout England and Wales to act with the Central Medical War Committee and to advise it as to local conditions and as to practitioners in the localities who could most easily be spared. The Committee of Reference of the Royal Colleges in England was set up early in 1916 to consider cases of doctors on the staffs of hospitals and medical schools in the metropolis, and such other special cases in England and Wales as might be referred to it. An Irish Medical War Committee was also established. Schemes were instituted by the Central Committees in England and Wales, and in Scotland, for the enrolment of all medical men up to the age of 45, the limit for general service in the R.A.M.C. The enrolled person gave an undertaking to accept service when called upon by the committee, and the Army Council undertook to apply to him the principle that a medical man thus offering himself should not be called upon to fulfil his obligation of commissioned service for more than twelve months consecutively.

"The passing of the second Military Service Act, 1916, had the effect of imposing compulsory service on all medical men under 41. The central medical committees, thereafter called 'professional committees,' were recognized by an Order in Council, and were entrusted with the duty of selecting at the right time in each case the particular medical men who could be spared from their civil work with least injury to the civil population, and of retaining in their civil work those most needed there in the public interest. The Army Council undertook to refrain from applying its compulsory powers as to combatant service to a doctor of military age if, and so long as, he was enrolled and undertook to serve, and if required did serve, as a commissioned officer in the R.A.M.C. whenever this might be found necessary by the central professional committee. When called on he was given the right of appeal to the central professional committee. If at the end of the first or any twelve months' service a medical man relinquished his commission, he, if under 41, remained liable to the Military Service Acts, but if he then enrolled he reverted to the position in which he was before he took a commission; that is to say, he went back amongst those from whom the central professional committees selected doctors for commissioned service in the R.A.M.C., subject to due consideration of the needs of the locality and his personal circumstances. The enrolment scheme continued to apply to doctors over military age, especially those from 41 to 45, and in June, 1916, shortly after the passing of the second Military Service Act, the War Office announced that it was prepared to give commissions in the R.A.M.C. to medical men between 45 and 55 willing to undertake whole-time general service in the United Kingdom. Incidentally it should be noted that newly qualified medical men automatically passed into the Reserve, and were commissioned in the R.A.M.C. (S.R.), subject only to their being pronounced physically fit on medical examination.

"On the establishment of the Ministry of National Service recruiting in all its branches was transferred from the War Office to that Ministry, and medical recruiting became especially the care of its medical department, with which the professional committees have been in communication throughout.

"At present temporary R.A.M.C. officers of military age on expiration of their contract are required, if they renew, to engage for the duration of the war. If an officer, however, does not wish to renew he retains his right of appeal to the professional committee, which, in deciding whether or not he should rejoin, takes into consideration the needs of the civilian population of the locality in which he practices and his personal circumstances. It is to be noted that medical officers of military age intending to relinquish their commissions after Oct. 31, 1917, were warned that they would probably be recalled shortly.

"The first clause of the new bill fixes the military age at from 18 to 51, but there is a proviso that by an Order in Council the upper limit of age may be raised to 56 as respects men generally, or as respects any class of men, and it shall be so fixed "as respects any person being a duly qualified medical practitioner." Clause 4 gives power to make regulations by an Order in Council to establish "special tribunals, committees, or panels for dealing with particular classes of cases," and to determine the grounds on which application may be made to the tribunals and the rights of appeal.

"The Central Medical War Committee, at its meeting on April 10, decided, after full discussion, not to press for the insertion of any amendment in the bill now before Parliament in so far as it relates to registered medical practitioners. It is felt that the older men who will now become subject to military service will in most cases serve their country best by placing themselves at the disposal of the central professional committees for medical work, in a military or civil capacity, which will release younger practitioners for active service. The method, no doubt, will vary according to local and individual conditions, but it would seem that schemes for local arrangements would produce less dislocation of practice than any general plan of long-distance substitution between the areas which are relatively understaffed and those which are more plentifully supplied with doctors. Although the total number of medical men who may be made liable to military service under the bill is large—between 6,000 and 7,000—it is unlikely that any considerable proportion would be called on; if this is so, only a minority would be directly affected.

"In the altered situation which will be brought about by the enactment of the bill, the Ministry of National Service will, doubtless, desire to remain in the closest collaboration with the Statutory Professional Committee. But it is probable that henceforward the decision on the indispensability of individual practitioners, or on questions of priority, will rest ultimately in the hands of the Ministry. The fullest use will, no doubt, be made of the advice and opinion of the professional committees, but, as in the case of all other tribunals, the last word will be said by the Ministry of National Service. In this respect the legal position will be changed, though it is not anticipated that in practice any conflict will arise between the professional committees and the Ministry."

A CORNER OF THE GREAT BATTLEFIELD

An American Surgeon in the Midst of Things

The Journal has received from Major George de Tarnowsky a description of the activities of the hospital to which he was attached during the recent drive. In the letter accompanying his statement he says:

> For four days we had the hospital full of Tommies; since that time the French have taken over the sector and we are doing advanced surgery on all severe "nontransportable cases," a rare opportunity to do major war surgery. Of the battle itself, events are still too recent to dare even mention a word about it. Suffice it to say that the English put up a splendid fight against overwhelming numbers. It was a close call for two or three days, but the hole is plugged up and we have confidence that the leak will not recur again. The spirit of the troops is magnificent.

France, April 12, 1918.

To the Editor: The great battle which began in the early morning hours of March 21, '18, found the Ambulance des Alliés with some two hundred wounded, seventy-five of whom were American, one of our divisions occupying a nearby sector jointly with the French.

In order to have all available beds possible at our disposal, the latter were evacuated on Paris by train and from thence by ambulance to U. S. Base Hospital at Neuilly. The French wounded were sent to the interior by train. All stood the journey very well. A few of the patients recently operated on were kept for a subsequent evacuation.

An atmosphere of tense excitement and uncertainty surrounded us. We knew that the thinly held British line had been overwhelmed by sheer weight of numbers and that the Tommies were falling back, making the enemy pay dearly for his gains. Just where the retreat would end was anybody's guess. The highway in front of the hospital was a seething mass of soldiers, artillery, munitions, etc., speeding north to check the invasion; an equally dense, infinitely pathetic mass of civilians were trekking south. Baby carriages, wheelbarrows, two and four-wheeled carts and carriages of all sorts passed before our eyes in an apparently unending stream. These poor people had just begun to live their lives over again, amidst familiar surroundings, when the stern necessities of the battle forced them, for the second time in four years, to abandon their homes and fields in order to seek shelter elsewhere.

Two girls, both under 20, stop in front of the operating room windows and lean against the parapet to rest. Taking turns, they had trundled a wheelbarrow, on which was a single black trunk, for miles along the dusty road. They, at least, will not fall in the hands of the Boche! An old grandmother pushes a baby carriage in which a pretty 4-year-old girl sits, clutching a wooden doll in her hands, while at her feet is a wicker basket containing a hen and its chicks! In a two-wheeled cart lies an infirm grandfather, with a goat and calf for company, while his daughter walks beside the horse's head and three boys tramp behind, clinging to ropes which dangle from the vehicle! The pictures are pathetically funny, and one tries to laugh—in order not to cry—for men have learned to cry in this war; cursing is inadequate to express the feelings which surge within!

Wounded, both English and French, began arriving on the morning of March 24; the earlier signs of military confusion had ceased, and the French had jumped into the breech, while the English, worn out by the terrific onslaught, but still full of fighting spirit, fell back on the town of ...... to reform. It was a magnificent exhibition of team work, carried out in the very midst of a desperate battle for the road to Paris! Three divisions against eleven, and the eleven could not get through!

LOCATION OF THE HOSPITAL

Without mentioning names of places, a short description of our location will explain the immense importance of this hospital during the battle. The first great rush brought the battle line seven miles north of us. We occupied almost the apex of a triangle, the base of which represented the battle line, the two sides two converging valleys along which the Boche hoped to push on to Paris. Had he been able to pour down either valley, our retreat toward Paris would have been cut off, as the junction of the two rivers takes place three miles south of the hospital grounds.

With no railway lines, bridges or canal locks within a mile, and no munition depots within three miles of us, we enjoyed a reasonable degree of security from shell fire or aerial bombs. The tiny village did, however, shelter troops who were constantly billeted there, and a long-range battery installed three hundred yards from the hospital barracks put us in real danger. The guns, most fortunately for us, only remained twenty-four hours, departing before the Boche avions had a chance to photograph their location. Shell fragments, bullets, and even pieces of shell casings from our own antiaircraft guns sprinkle the roofs and grounds about us, but this small diversion has been of almost nightly occurrence for the past month and we have grown accustomed to the avion raids. The vicissitudes of the great battle thus made us the nearest surgical formation in this sector, capable of operating on all "nontransportable" cases. Owing to their exposed position, all the large hospitals east and west of us had been compelled to evacuate on the second day of the battle.

The fact that only two surgical teams, one French, one American, were attached to the hospital when the attack began, was a serious handicap, but the American Red Cross promptly sent reinforcements, with a supply of food and four motor trucks, the latter placed at our constant disposal in case a hasty evacuation became imperative.

By Monday, March 25, the war news was so conflicting, yet so generally discouraging, that the directress of the hospital very suddenly ordered a general evacuation. At 2 o'clock, on the morning of March 26, everybody was awakened and told to be dressed in ten minutes! The peculiar arrangements and combination of circumstances which allowed a civilian directress to order a military evacuation, are not germane to this letter, and will, therefore, not be mentioned. Suffice it to say that the French staff and personnel obeyed said order to the letter.

Approximately one hundred and fifty patients were transferred by ambulance to the hospital boat belonging to this formation, with the French staff and personnel and all of the nurses, the evacuation consuming four hours. As the boat was docked in the canal, a mile from the hospital, the transfer was extremely rapid and easy. Needless to say, there was no opportunity for cleaning up the wards or even storing away any of the material. Chaos and confusion were left behind.

THE HOSPITAL MOVED—NOT

Major John J. Moorhead, M.R.C., U.S.A., and myself, not being under the direct orders of either the directress or the French Service de Santé, expressed our firm desire and intention of remaining behind. There was plenty of work ahead of us; the Chief Surgeon A. R. C., under whose orders we were detailed for temporary duty, had not ordered us to evacuate, and we both felt that we could make a quick getaway if the military situation absolutely demanded our taking such a step.

Our request was granted. One patient, suffering from a lesion of the left femoral vessels and pelvic peritonitis, was left behind. By 6 a. m., March 26, the staff and personnel of the hospital consisted of Major George de Tarnowsky, M.R.C., U.S.A.; Major John J. Moorhead, M.R.C., U.S.A.; Corporal Bonne, French Service de Santé; Corporal Brandinière, cook; Mme. Louis, kitchen helper; Louis, blind retainer; and Jean Legros, gardener.

The two French surgeons envy us our good luck; there is, however, plenty of work for them to do on the boat, as many of the wounded are evacuated before operation. The nurses, English, Irish, Canadian and American women, without a single exception, volunteered to remain with us; we unfortunately had no military authority over them and they were compelled to go with the French staff.

Mme. Louis, fearful lest her blind husband be left behind if we have to evacuate, makes me repeatedly promise that he will be put in one of the A. R. C. trucks. She, on the other hand, swears that she will put her chickens in a crate so that we can have fresh fowl to eat all the way to Paris! Neither husband nor chickens must be allowed to fall in the hands of the Boche!

Left to our own resources, Major Moorhead, Corporal Bonne and I prepared forty beds, sterilized several sets of instruments and stored away the uniforms, arms, etc., which had been left behind. We fortunately have a large supply of sterile dressings, cotton and bandages.

Using the A. R. C. supplies which had been left under our charge, we distributed corned beef, cheese, crackers, chocolate, etc., to scores of hungry soldiers who passed the hospital gates. The cook presided over this distribution with much gusto, adding coffee or wine from the hospital stores.

Wounded soldiers began to arrive early in the afternoon, and we prepared to operate on the urgent ones. At 6 p. m., Capt. Peter M. Keating, M.R.C., U.S.A., very opportunely arrived from Paris and was immediately impressed. The electric plant having been disconnected, candles, stuck on a wooden board, and two lamps served for lighting purposes. This compels us to use chloroform instead of ether anesthesia. From 7 p. m. to 4 a. m., we three surgeons performed twenty-six consecutive operations. The A. R. C. truck drivers were impressed as stretcher bearers and orderlies, while Corporal Bonne attended to the sterilizing. At 10 p. m., several American volunteer nurses, belonging to what is known as Mrs. Daly's equipe or team, arrived from Compiègne and immediately rendered invaluable assistance.

We had barely retired for a few hours' sleep when at dawn of March 27, several A. R. C. officials drove up with very alarming news, advising us to evacuate immediately! All of the cases operated on were loaded in ambulances and trucks and taken to Compiègne, five miles south of us, where they left on the last sanitary train, all the hospitals in that town having received orders to close up and depart.

Before coming to any decision regarding our small, therefore very mobile, staff, Major Moorhead and the writer drove to the hospital center of Villers-s/Coudon, three miles northwest of the Ambulance des Alliés. The C. O. informed us that he had already received three evacuation orders and as many counter-orders, the last one to the effect that he must evacuate all wounded, but that his hospital would continue to receive slightly wounded cases; the latter, however, were not to be operated on but merely dressed and put on a sanitary train. We were assured that any further evacuation orders would be transmitted to us by courier, as our phone had been cut; this promise was most welcome and reassuring.

After holding a consultation with Major Moorhead, we decided to stay. Late in the afternoon, our French C. O., with the two French surgeons, returned from the boat which they had left below the Compiègne bridges. With fourteen volunteer American nurses and two surgical teams, we were able to operate steadily throughout the day and night.

At 3 a. m., March 28, a courier from Villers-s/Coudun Hospital arrived, with a message from the C. O. to the effect that he had just received orders to evacuate all wounded and prepare to retire with his supplies and personnel. While our French C. O. went to army headquarters nearby for final orders, the wounded were prepared for evacuation and sent to the boat which had docked in the canal, eight miles south of us. Returning from headquarters, our C. O. reported that we would be allowed to remain at our post for the time being, but that there should be a daily evacuation of all wounded after their operation. Our canal hospital boat, propelled by its own steam and fitted up with seventy bunks and a small operating room, had been in commission about six months, rendering good service. Its utility, during the battle, was considerable. For instance, on March 24, in the thickest of the fight, it went up the canal to Noyon and came back with 180 wounded, seventy of whom were "lying" cases, the balance being able to sit here, there and everywhere, above and below decks. During two of the "en masse" evacuations from the hospital, *forty-six* operations were performed on board the boat by the French surgical team.

March 28 and 29, the operations continued steadily, one surgeon at a time managing to get a few hours rest. A second American team, consisting of Capts. Charles Farmer, Philip Wilson and First Lieut. Thomas S. Hardy, all M. C., U. S. R., arrived from Paris. Unfortunately, Captain Keating was recalled to Paris so that, during the absence on the boat of the French team, we were still reduced to two operating teams, with a spare surgeon for stimulations, dressings, etc. On this same date, March 29, seven of our nurses returned, and the Mrs. Daly equipe departed. While new wounded continued to tax our operative capacity to its utmost, the general news of the battle became more reassuring; the Hun flood had been brilliantly dammed. We began to keep our operated cases until all danger of secondary hemorrhage or sepsis had passed, only evacuating when our nursing capacity was absolutely overtaxed.

Owing to our nearness to the firing line, the entire nursing staff, for the boat and hospital, was kept down to twelve nurses and their matron..with some thirty French orderlies. This personnel enabled us to hospitalize as many as seventy-five severely wounded cases at a time, but no more.

By Wednesday, April 3, we had definitely organized three operating teams, working turn and turn about in ten hour shifts. A ten-hour shift was decided on in order to give each team an equal number of night hours in the operating room, admissions being heaviest after nightfall. When not operating, we received, diagnosed and prepared cases, dressed our own cases and rested whenever we could.

Early in the battle, our trunks and lockers had been sent to Paris for safe keeping and, with the contents of a suitcase for our entire wardrobe, we lived from day to day, stripped for the surgical fight which it is our lot to wage. For almost two weeks we had no postal service; at present we occasionally receive mail and can write about the weather and the safety of our persons to the loved ones at home.

Distractions abound; not a day passes without several aerial fights; bombardments start up at all hours of the day and night and we keep wondering whether Fritz will not drop a shell or bomb "by mistake" on our modest Red Cross group of buildings!

While Major Moorhead and I have tabulated all of the cases which have passed through our hands, there has been no opportunity to classify the operations and results. Suffice it to say, for the present, that during the first great rush, i. e., from March 25 to April 3, when the three teams began their regular schedule, 149 operations were performed, with a total mortality of six cases. Two of the six were moribund on admission, no operation being possible; of the remaining four, two were intrathoracic and two intra-abdominal wounds with profuse hemorrhage. One hundred and three operations were performed at the hospital; forty-six on the boat.

Just how long this emergency is to continue, nobody knows. We intend sticking as long as there are wounded to succor and our orders remain unchanged. That we shall still be operating in the same hospital when this letter reaches you, is the earnest wish of

George de Tarnowsky, Major, M. R. C., U. S. Army.
Chief Surgeon, Ambulance des Alliés.

ORDERS TO OFFICERS OF THE MEDICAL CORPS AND OF THE MEDICAL CORPS OF THE NATIONAL ARMY

To Camp Grant, Rockford, Ill., base hospital, from Camp Sheridan, Major GEORGE W. JEAN.

To Camp [illegible] Spartanburg, S. C., as assistant to camp surgeon, from [illegible] or SIDNEY L. CHAPPELL.

To Fort [illegible] examination to determine his fitness for active d[illegible] W. FARR.

To Fort Schuyler, N. Y., for duty, from Camp Hancock, Major J. MARKWOOD PETERS.

To Fort Slocum, N. Y., for duty, from Governors Island, Lieut.-Col. CHARLES Y. BROWNLEE.

To Fox Hills, N. Y., for duty, from Hoboken, Lieut.-Col. HENRY H. RUTHERFORD.

To Governors Island, N. Y., for duty, from Fort Slocum, Col. FRANCIS M. C. USHER.

To Rockefeller Institute for instruction in chemistry, from Army Medical School, Lieut. CYRUS B. WOOD.

To Washington, D. C., for consultation and on completion *to his proper station*, from Hoboken, Col. JAMES M. KENNEDY; from Fort Porter, Lieut.-Col. THOMAS D. WOODSON for conference, and on completion *to his proper station*, from Camp Lee, Lieut.-Col. THOMAS L. RHOADS.

ORDERS TO OFFICERS OF THE MEDICAL RESERVE CORPS

Alabama

To Camp Gordon, Atlanta, Ga., base hospital, from Army Medical School, Lieut. MONTE LER. MOORER, Mt. Vernon; from Camp Upton, Lieut. JOSEPH M. WELDON, Tallassee.

To Camp Jackson, Columbia, S. C., for duty, Lieut. JAMES L. BOOTH, Buhl.

To Camp Kelly, San Antonio, Tex., for duty, from Camp MacArthur, Lieut. JAMES H. PHILLIPS, Dora.

To Fort McPherson, Ga., for temporary duty, from New York City, Major WESLEY E. DRENNEN, Birmington.

To Fort Oglethorpe for instruction, Lieuts. CHARLES E. TEDDER, Emsley; WILLIAM C. HANNON, Mobile; MILNER H. ESKEW, Selma.

To Newport News, Va., for duty, Lieut. JOHN P. COCHRAN, Catchie.

To Sacramento, Calif., Mather Field, Signal Corps Aviation School, from Camp Kelly, Capt. JOHN R. OSWALT, Union Springs.

Honorably discharged on account of physical disability prior to entrance into the service, Lieut. CHARLES W. BRASFIELD, Linden.

Arizona

To Camp Cody, Deming, N. M., base hospital, Capt. JOHN E. BACON, Miami.

Arkansas

To Camp Jackson, Columbia, S. C., for duty, Capt. ELMER E. HOLT, Mena; from Fort Oglethorpe, Lieut. HERBERT S. WATSON, Earl.

To Camp Kelly, San Antonio, Tex., for duty, from Camp MacArthur, Lieuts. BOULANGER GWALTNEY, Haskell; JAMES M. BEST, Monticello.

To Fort Oglethorpe for instruction, Lieuts. OSCAR BARKSDALE, Bassett; FELTON W. LANDRUM, Driggs.

Honorably discharged on account of physical disability existing prior to entrance into the service, Lieut. THOMAS M. FLY, Little Rock.

California

To Camp Crane, Allentown, Pa., base hospital, from Camp Travis, Major JAMES R. MOORE, Los Angeles.

To Camp Fremont, Palo Alto, Calif., for duty, Lieut. FRANK M. LAWSON, Willows.

To Camp Gordon, Atlanta, Ga., for duty, *from Camp Doniphan*, Capt. AMBROSE E. EDGERTON, Stockton.

To Camp Hancock, Augusta, Ga., *base hospital*, from Camp Bowie, Lieut. THOMAS R. PETCH, Eureka.

To Camp Kearny, Linda Vista, Calif., base hospital, Capt. GEORGE G. HUNTER, Los Angeles; Lieut. SAMUEL J. MATTISON, *Pasadena*.

To Camp Lewis, American Lake, Wash., base hospital, Lieuts. EDWIN H. McMILLAN, Pasadena, Walter C. Smallwood, Richmond.

To Camp Pike, Little Rock, Ark., base hospital, from San Francisco, Capt. MORTON R. GIBBONS, San Francisco.

To Camp Wheeler, Macon, Ga., base hospital, *from Fort McHenry*, Capt. HOWARD C. NAFFSIGER, San Francisco.

To Fort Riley for instruction, Capt. WILLIAM V. CHALMERS-FRANCIS, Los Angeles; Lieuts. WILLIAM R. McDANNELL, Los Angeles; ROY H. PARKINSON, San Francisco.

To New York City, Orthopedic Hospital, *for instruction*, from Army Medical School, Capt. ERNEST W. CLEARY, San Francisco.

To Rockefeller Institute for instruction *in laboratory work*, from Camp Fremont, Lieut. L. J. SCHERMERHORN, Stockton.

Canal Zone

To report to the Governor, Panama Canal, for duty, Capt. LEWIS B. BATES, Ancon.

Colorado

To Camp Cody, Deming, N. M., base hospital, Capt. WALTER F. CHURCH, Greeley.

To Camp Fremont, Palo Alto, Calif., for *duty*, *Lieut. FRANK DUNKLE*, Denver.

To Camp Gordon, Atlanta, Ga., base hospital, from Camp Logan, Lieut. TOM R. KNOWLES, Colorado Springs.

To Camp Wadsworth, Spartanburg, S. C., base hospital, from New York City, Capt. LEWIS H. McKINIS, *Colorado Springs*.

To Newport News, Va., for duty, from Fort Riley, Lieut. VIVIAN E. PENNOCK, Longmont.

To Rochester, Minn., Mayo Clinic, for instruction, and on completion *to his proper station*, from Camp Doniphan, Major HARRY S. FINNEY, Denver.

To Rockefeller Institute for instruction in the treatment of infected wounds, and on completion *to Camp Shelby*, Hattiesburg, Miss., base hospital, from Fort Riley, Capt. THOMAS A. STODDARD, Pueblo.

Connecticut

To Camp Sheridan, Montgomery, Ala., to examine the command for nervous and mental diseases, from New York City, Capt. WILLIAM R. MILLER, Southington.

To Camp Upton, Long Island, N. Y., as orthopedic surgeon, from Army Medical School, Lieut. LEVERNE HOLMES, *Manchester*.

To Fort Ontario, N. Y., for temporary duty, Capt. PHILIP D. BUNCE, Hartford.

To Governor's Island, N. Y., for duty, Lieut. GEORGE P. CHENEY, New London.

To Newport News, Va., for duty, from New York City, Capt. JOHN *B. GRIGGS, Hartford*.

To Rockefeller Institute for instruction, in the treatment of infected wounds and on completion *to Camp Gordon*, Atlanta, Ga., base hospital, *from Camp Upton*, Major WILLIAM F. VERDI, New Haven. On completion *to Camp Logan*, Houston, Texas, *base hospital*, Lieut. ROBERT F. SCHELL, New Haven.

District of Columbia

To Camp Crane, Allentown, Pa., base hospital, from Dansville, N. Y., Capt. CHARLES S. ROBBINS, Washington.

To Camp Meade, Annapolis Junction, Md., for duty, from Fort Oglethorpe, Lieut. VIRGIL B. WILLIAMS, Washington.

To Fort Oglethorpe for instruction, Capt. CHAUNCEY L. BARBER, Washington.

To Pittsburgh, Pa., Carnegie Bldg., for instruction, and *on* completion *to Camp Hancock*, Augusta, Ga., base hospital, from Fort Oglethorpe, Lieut. WILLIAM H. NORTON, Washington.

Florida

To Camp Fremont, Palo Alto, Calif., for duty, from *Camp* Lewis, Capt. JAMES D. PASCO, *Jacksonville*.

To Camp Gordon, Atlanta, Ga., for duty, from Fort Oglethorpe, Lieut. WILLIAM S. GRAMBLING, Miami.

To Camp Greene, Charlotte, N. C., base hospital, from Camp McClellan, Capt. JOHN D. MACRAE, Tampa.

To Camp Wheeler, Macon, Ga., base hospital, Lieut. EDGAR E. STRICKLAND, Hawthorne.

To Fort Oglethorpe for instruction, Lieut. CAREY T. ROGERS, Jacksonville.

To Newport News, Va., as orthopedic surgeon, *from* Army Medical School, Capt. JOHN W. ALSOBROCK, Plant City.

Honorably discharged, Lieut. JOEL W. HOOD, *Ocala*. On account of physical disability existing prior *to entrance* into the service, Lieuts. OVEDIA F. GREEN, Mayo; JOHN T. BRADSHAW, San Antonio.

The following order has been revoked: *To Camp Gordon*, Atlanta, Ga., for duty, Capt. JOHN S. TURBERVILLE, Century.

Georgia

To Americus, Ga., for duty, from Fort Oglethorpe, Capt. JOHN M. SPENCE, Camilla; from Atlanta, Lieut. JAMES M. J. LUKE, Fitzgerald.

To Camp Dix, Wrightstown, N. J., as orthopedic surgeon, from Fort Oglethorpe, Lieut. KENETH S. HUNT, Milner.

To Camp Gordon, Atlanta, Ga., base hospital, Capt. HANSELL CRENSHAW, Atlanta. [illegible] from Fort Oglethorpe, Lieuts. CLEVELAND D. WELCHEL, Gainesville; LOUIS B. ROYAL, Girard; CARL S. PITTMAN, Ty Ty.

To Mineola, L. I., N. Y., Signal Corps Aviation School, from Atlanta, Capt. JOHN H. HALL, Atlanta.

To New Orleans, Charity Hospital, for instruction, and on completion *to Camp Gordon*, Atlanta, Ga., base hospital, from Camp Gordon, Capt. FRANK BIRD, Valdosta.

To Rockefeller Institute for instruction in laboratory work, and on completion *to Army Medical School for duty, from Camp Bowie*, Lieut. CALVIN W. DAVIS, Atlanta.

Honorably discharged on account of physical disability existing prior to entrance into the service, Lieut. JOHN W. BRADLEY, Woodstock.

Illinois

To Boston, Mass., Harvard *Graduate School of* Medicine, *for* instruction, Capt. CLAUDE R. G. FORRESTER, Chicago.

To Camp Cody, Deming, N. M., base hospital, from Camp Pike, Major WILLIAM FULLER, Chicago; from Camp Upton, Lieut. IRA McKINNEY, Chicago.

To Camp Devens, Ayer, Mass., base hospital, from Newport News, Major FRANK S. CHURCHILL, Chicago; from Springfield, Mass., Capt. WILLIAM P. MacCRACKEN, Chicago.

To Camp Crane, Allentown, Pa., base hospital, from Army Medical School, Lieut. ARTHUR E. SIMONIS, Fremont.

To Camp Dix, Wrightstown, N. J., base hospital, Lieut. THOMAS V. McLAUGHLIN, Wilkes-Barre.

To Camp Fremont, Palo Alto, Calif., for duty, from Camp Lewis, Lieut. FRANK E. SMITH, New Kensington.

To Camp Gordon, Atlanta, Ga., base hospital, from Camp Upton, Lieut. GARDNER A. SAYRES, Lancaster; from Lakewood, Lieut. MILTON H. BACHMAN, McKeesport. For duty, Lieut. OLIVER K. SPEER, Tamaqua.

To Camp Grant, Rockford, Ill., base hospital, from New York City, Lieut. CHARLES H. KIRK, Homer City.

To Camp Logan, Houston, Texas, for duty, from Fort Oglethorpe, Lieut. WILLIAM J. McGRANER, Port Alleghany.

To Camp MacArthur, Waco, Texas, base hospital, from Fort Oglethorpe, Lieut. ROBERT W. RICHARDS, Shingle House.

To Camp Meade, Annapolis Junction, Md., base hospital, Lieuts. PHILIP A. TRAU, Philadelphia; WILLIAM H. M. IMHOFF, Willow Grove. To examine the command for nervous and mental diseases, Lieut. JACOB PEARL, Philadelphia.

To Camp Pike, Little Rock, Ark., to examine the command for mental and nervous diseases, from Ann Arbor, Lieut. WILLIAM W. McC. MILLS, Du Quesne.

To Camp Sheridan, Montgomery, Ala., for duty, from Camp Gordon, Capt. FERDINAND L. BENZ, Pittsburgh; from Fort Oglethorpe, Lieut. GEORGE H. B. TERRY, Wyalusing.

To Cape May, N. J., for temporary duty, from Philadelphia, Capt. BURTON K. CHANCE, Philadelphia.

To Colonia, N. J., for temporary duty, Lieut. GEORGE W. SCHLINDWEIN, Erie.

To Columbus Barracks, Ohio, for temporary duty, Lieut. DEN C. LINDLEY, New Castle.

To Fort [illegible] ction, Lieuts. JOHN H. MOSS, Archbald; [illegible] Barnesboro; PAUL M. HUNSICKER, Beaver [illegible] KOONS, Conyngham; WILLIAM T. DONCASTER, Jeannette; NATHAN ASHINSKY, Pittsburgh; JOHN F. SPEARMAN, Sharon; from New York City, Lieut. SIDNEY KALLAWAY, Homestead.

To Fort Thomas, Ky., for duty, from New York City, Lieut. HORACE L. CARNCORSS, Philadelphia.

To Rock Island, Ill., for duty, and on completion *to his proper station*, from Camp Wheeler, Capt. VINCENT J. FENERTY, Philadelphia.

To Washington, D. C., St. Elizabeth's Hospital, for intensive training, from Newport News, Capt. WILLIAM S. RUCH, Carlisle.

Honorably discharged on account of physical disability existing prior to entrance into the service, Lieuts. CLOY G. BRUMBAUGH, Huntingdon; HARRY A. DUNCAN, Philadelphia; LEO. DEL. PARRY, Rock Glen.

Resignation of Lieut. FRANKLIN W. MATHEWSON, Oakdale, accepted.

The following orders have been revoked: *To Camp A. A. Humphrey*, Accotink, Va., for duty, Lieut. HARRY A. DUNCAN, Philadelphia. *To Camp Sheridan*, Montgomery, Ala., for duty, from Camp Gordon, Capt. FERDINAND L. BENZ, Pittsburgh.

South Carolina

To Baltimore, Md., John Hopkins Hospital, for instruction in pathology, from Rockefeller Institute, Lieut. FRANCIS A. COWARD, Columbia.

To Camp Gordon, Atlanta, Ga., for duty, from Fort Oglethorpe, Lieut. WILLIAM R. BLACKMON, Rock Hill.

To Williamsbridge, N. Y., for observation and treatment, from Fort Riley, Lieut. SAMUEL S. BRUINGTON, Georgetown.

Honorably discharged on account of physical disability existing prior to entrance into the service, Lieut. HERBERT H. ACKER, Anderson.

South Dakota

To Camp Kelly, San Antonio, Texas, for duty, from Camp MacArthur, Lieut. JAMES H. CRAWFORD, Castlewood.

To Fort Riley for instruction, Lieut. CHARLES A. WILLIAMS, Doland.

To Kansas City, Mo., for duty, and on completion *to his proper station*, from Fort Leavenworth, Lieut. GEORGE A. STEVENS, Sioux Falls.

Honorably discharged on account of physical disability existing prior to entrance into the service, Lieut. JAMES C. WALTON, Isabel.

Tennessee

To Camp C[illegible] or duty, from Fort Oglethorpe, Lieut. GROVER C. [illegible]

To Camp [illegible] Park, Ga.; *Fort Oglethorpe*, and *Memphis, Te*[illegible] m Camp Hancock, Capt. LEE A. STONE, Memphis.

To Camp Gordon, Atlanta, Ga., base hospital, from Camp Upton, Capt. CHARLES L. GOODRICH, Fayetteville.

To Camp Greene, Charlotte, N. C., base hospital, from Camp Gordon, Capt. LEON L. MEYER, Memphis.

To Camp Logan, Houston, Texas, for duty, from Fort Oglethorpe, Lieut. DAVID H. JAMES, Nashville.

To Camp McClellan, Anniston, Ala., as assistant to the camp surgeon, from West Point, Capt. JOHN M. LEE, Nashville.

To Rochester, Minn., Mayo Clinic, for instruction, and on completion to Camp Pike, Little Rock, Ark., base hospital, from Fort Oglethorpe, Capt. CARL T. SPECK, Cleveland. On completion *to Camp Bowie*, Fort Worth, Texas, base hospital, Lieut. WILLIAM D. RICHARDS, Etowah.

To Rockefeller Institute, for instruction in the treatment of infected wounds, and on completion *to his proper station*, from Fort Oglethorpe, Major FRANK D. SMYTHE, Memphis.

To Washington, D. C., St. Elizabeth's Hospital, for intensive training, from Camp Wadsworth, Lieut. PHILIP I. TRENTZACH, Rives.

Honorably discharged, Lieut. JOHN W. FROST, Dyer.

The following order has been revoked: *To Hoboken, N. J.*, for duty, Capt. GEORGE E. VAUGHAN, Clarksville.

Texas

To Army Medical School, for instruction, Lieut. HORACE H. HILLIARD, Canton.

To Camp Colt, Gettysburg, Pa., for duty, from Fort Oglethorpe, Lieut. HERSHALL LAFORGE, Kingsbury.

To Camp Devens, Ayer, Mass., base hospital, from Fort Oglethorpe, Lieut. DOLPHUS E. COMPERE, Dallas.

To Camp Gordon, Atlanta, Ga., base hospital, from Camp Joseph E. Johnston, Capt. JOSEPH E. JOHNSTON, Kirvin; from Fort Oglethorpe, Lieut. CLAUDE E. PIERSALL, Wolfe City.

To Camp Greene, Charlotte, N. C., base hospital, from Camp Travis, Capt. ROBERT F. MILLER, San Antonio; from Camp Upton, Capt. OWEN R. O'NEILL, Clarksville; from Fort Oglethorpe, Lieut. WILLIAM A. LEE, Denison.

To Camp Sheridan, Montgomery, Ala., base hospital, from Camp Hancock, Major WALLACE KALSTON, Houston.

To Rockefeller Institute for instruction in laboratory work, and on completion *to Army Medical School* for duty, Lieut. GEORGE M. JONES, Smithville.

To Walter Reed General Hospital, Takoma Park, D. C., for observation and treatment, Major WALLACE RALSTON, Houston.

Honorably discharged, Lieut. JOHN J. TRIBLE, Port Lavosa.

The following order has been revoked: *To Army Medical School* for instruction, Lieut. FREDERICK L. STORY, Ennis.

Utah

To Camp Wheeler, Macon, Ga., base hospital, from Fort Riley, Lieut. JOHN O. COOK, Sunnyside.

To Fort Riley for instruction, Lieut. HARRY S. SCOTT, Salt Lake City.

Vermont

To Camp Laurel, Laurel, Md., for duty, from Fort Oglethorpe, Lieut. JOHN M. CAISSE, Vergennes.

To Fort Oglethorpe for instruction, Capt. WALTER J. WHITE, Middlebury.

Virginia

To Camp Dix, Wrightstown, N. J., as orthopedic surgeon, from Fort Oglethorpe, Lieut. ERNEST B. MILLER, Elkton.

To Camp Gordon, Atlanta, Ga., base hospital, Lieut. FRANK D. WILLIS, Newport News.

To Camp Greene, Charlotte, N. C., base hospital, from Fort Oglethorpe, Lieut. PAUL DAVIS, Roanoke.

To Fort Oglethorpe for instruction, Lieuts. HERMAN P. DAVIDSON, Lexington; EDGAR A. MOORE, Paris; WALTER D. SIMMONS, Richmond; HARRY C. HARRIS, Roanoke; WILLIAM L. VARN, Walkerton; from Army Medical School, Lieut. ARTHUR HOOKS, Blackstone.

Honorably discharged on account of physical disability existing prior to entrance into the service, Lieut. GEORGE Y. MacMURPHY, The Plains.

Washington

To Camp Lewis, American Lake, Washington, for duty, from Portland, Ore., Lieut. JOSEPH HEHIR, Sedro-Woolly.

To Fort Monroe, Va., for temporary duty, from New York City, Capt. HARRY G. WILLARD, Tacoma.

To Fort Riley for instruction, Lieut. WILLIS H. HALL, Seattle.

To Hoboken, N. J., for temporary duty, from New York City, Capt. HARRY E. ALLEN, Seattle.

West Virginia

To Camp McClellan, Anniston, Ala., base hospital, Capt. HARRY M. LAVILLE, Littleton.

Wisconsin

To Camp Gordon, Atlanta, Ga., base hospital, from Boston, Lieut. JOHN W. HANSEN, Milwaukee.

To Camp Kelly, San Antonio, Texas, for duty, from Camp MacArthur, Lieuts. GEORGE W. HARRISON, Ashland; JAMES H. FOWLER, Lancaster.

To Edgewood, Md., base hospital, Lieut. EMIL H. SUTTER, Milwaukee.

The following orders have been revoked: *To Camp Cody*, Deming, N. M., base hospital, Capt. GERHARD A. BADING, Milwaukee. *To Fort Riley* for instruction, Lieut. KNUTE A. RUETHIN, Ridgeland.

Wyoming

To Fort Riley for instruction, Lieut. EDWARD R. SCHUNK, Dietz.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest; such as relate to society activities, new hospitals, education, public health, etc.)

DISTRICT OF COLUMBIA

Washington Conserves Its Supply of Nurses for the Civil Population.—Washington is suffering from a shortage of graduate nurses. So many nurses have gone into the service of the Army, Navy, and Red Cross, and the population of the city has been so largely increased that the Medical Society of the District of Columbia and the Town and Country Nursing Service of the American Red Cross have felt it necessary to take action to conserve the available supply of graduate nurses. During March, 1918, the Nurses' Registry was able to answer only seventy-three requests for graduate nurses out of a total of 338 requests filed. A public appeal contains the following recommendations:

1. No person should be allowed to have a graduate nurse for minor illness or any purpose other than the care of a seriously ill patient. Nurses are now being retained by many people simply as companions and children's caretakers.
2. A graduate nurse should not be retained on a case after convalescence is well established.
3. Hourly nurses and visiting nurses should be used as much as possible in place of full-time, resident nurses.
4. Patients in hospitals should be cared for by the pupil nurses unless very seriously ill.
5. Women who have taken the Red Cross home nursing course should endeavor to take care of those sick in their own families.
6. Young women of education should be urged to enter training schools for nurses.
7. The public generally should supply the funds to make it possible for the training schools to increase their classes.

If people understand the situation and are willing to practice self-denial, the present supply of nurses can be so wisely and frugally distributed that all imperative needs will be met—and the seriously sick will be cared for.

To make such nurses as are available serve in those places where they can do the greatest possible good, the Medical Society of the District of Columbia has adopted the following resolution and appealed to its members to be guided by the principles laid down in it.

> That the society recognizes the prevailing and increasing shortage of trained nurses and urges upon its members the duty of distributing the services of nurses still available in such manner as will best serve the public good; it therefore recommends that members will (1) discourage the employment of trained nurses except in cases in which the safety of the patient demands skilled care; (2) release nurses from the care of patients at the earliest possible moment, so as to make their services available to others; and (3) where possible utilize the service of hourly nurses and practical nurses.

FLORIDA

State Meeting.—The Florida State Medical Association will meet at Tampa, May 15 and 16, for the 1918 session.

ILLINOIS

Chicago

Report of Visiting Nurse Association.—The twenty-eighth annual report of the Visiting Nurse Association of Chicago describes the association as "a field hospital furnishing skilled nursing care to the sick in their own homes" and shows that during 1917 there were 241,352 visits made in the homes of 34,427 patients, 32,488 of whom were new patients. There were ninety-six nurses on the staff whose work is classified into special services.

KENTUCKY

Trachoma.—Fifty cases of trachoma have been discovered in schools in Jefferson County outside of Louisville by officials of the U. S. Public Health Service, and Surg. John McMullen of the service has come to Louisville to aid in treating this disease.

ARYLAND

Personal.—Drs. Hugh Hampton Young and George H. Hocking have been reappointed members of the state lunacy commission by Governor Harrington. Dr. Young, who is president of the commission, is now in France, and during his absence Dr. Hocking is acting president.

Coroners Appointed.—The following physicians have been appointed by the governor as coroners for the different sections of Baltimore City: southwestern, Dr. James M. Fenton; eastern, Dr. Henry L. Sinskey; northern, Dr. John J. Morrissey; northwestern, Dr. James G. Wiltshire; western, Dr. Harry K. Gorsuch; central, Dr. William T. Riley; southern, Dr. Otto M. Reinhardt; northeastern, Dr. James K. Insley; at large, Dr. F. Edward Smith.

To Enlarge Hospital No. 7.—Plans are under way and building operations will begin at once to enlarge General Hospital No. 7, the government hospital for soldiers and sailors who become blind or deaf in the war, located just outside of Baltimore. Some of the new buildings will be used as dormitories for the military staff of the hospital and others as classrooms, where the men will be given vocational training as a means of support in spite of their handicap.

MISSOURI

Action Taken Regarding Disloyalty.—The Missouri State Medical Society, concurred in by the St. Louis Medical Society, has agreed by resolution that any member of these societies who in any way gives aid and comfort to the enemy is disqualified for membership. Under this action, a committee has been appointed by the St. Louis Medical Society to inquire into charges made by Dr. Koetter as to the loyalty of Dr. Charles H. Weisenberg, the report having been made to the society at its meeting, April 20.

NEW YORK

Personal.—Mildred Penrose Stewart, M.A., P.H., who obtained her M.A. degree in public health from the University of California, has been appointed director of the Dutchess County Health Association, with headquarters at Poughkeepsie. She is a graduate of Vassar, 1908, and for seven years taught physiology and hygiene in Pratt Institute, Brooklyn.——Dr. Franklin C. Graves, chief of the Bureau of Vital Statistics of Buffalo, has been appointed acting health commissioner, succeeding Dr. Francis E. Fronczak, who has been commissioned major, M. R. C.——The employees of the Buffalo Health Department, April 2, presented former Health Commissioner Major Francis E. Fronczak, M. R. C., with a military trunk and hand bag. Major Fronczak left for Washington, April 6.——Dr. Daniel Pugh, Utica, who has been serving in France with the Red Cross and who has recently been under treatment in the American Woman's Hospital for Officers in London, is now on duty in the Military Hospital in Liverpool.——Dr. James W. Charters, Buffalo, fractured his right arm, March 22, while cranking his automobile.——Dr. Carl G. Zimmerman, Elmira, who has been in a hospital for seven weeks, has recovered and resumed his practice.

New York City

Investigation of Randall's Island.—Commissioner Coler of the charities department is conducting an investigation of the institutions on Randall's Island which are under the direction of the department of charities. It is alleged that administrative conditions are unsatisfactory.

Three More Hospitals to Care for Wounded Soldiers.—The Montefiore Home and the Hebrew Orphan Asylum have outlined plans for extending the work of these institutions to aid the government in its care of wounded soldiers. The government has accepted the offer of 100 beds in the Montefiore Home on Gunhill Road in the Bronx, near the Columbia War Hospital. The newly erected private hospital of the Montefiore Home has also been placed at the disposal of the government for the care of returning incapacitated officers. This offer is now under consideration by the medical department. The board of directors of the New York Ophthalmic Hospital announce that, during the second year of the war, the hospital will specialize in the injuries to soldiers' eyes. It will give surgical and medical attention to drafted men and recruits, to disabled and wounded soldiers and to dependents of soldiers. It will also give special attention to the training of doctors and nurses for war work, especial emphasis being given to the care of diseases of the eye, ear, nose and throat.

Health Department Changes Head.—Dr. Lewis J. Amster, following his refusal to accede to the demand of Mayor Hylan that he should remove Drs. Abraham Jacobi and Sigismund S. Goldwater from the medical advisory council of the health department, sent in his resignation as health commissioner, April 29. In giving his reasons for refusing to hold office any longer, Dr. Amster objected to continuous interference and petty direction from the mayor; to the holding up of requests for the filling of important vacancies in the department; to suggestions for the successive abolishment of baby health stations maintained by the department; to the holding up of requests for other important appropriations and inaction in clearing up garbage and ashes in the streets; to the executive order that bureau heads be summarily dismissed on the ground that they held their positions illegally; to the turning over of graft investigations to the civil service commission, and the transference of the Otisville sanatorium to the federal government without conferring with the commissioner. Dr. Royal S. Copeland has been appointed to succeed Dr. Amster. One of the new commissioner's first official acts was to suspend Dr. Lucius P. Brown, director of the bureau of food and drugs, pending trial on charges made by the new health commissioner. Dr. Copeland gives as his reason for suspending Dr. Brown the fact that the latter made public his reply to the attack made on the conduct of the bureau of food and drugs by Chairman James E. McBride of the civil service commission. The committee on wartime problems of New York Academy of Medicine has adopted resolutions, which were sent to Dr. Amster, applauding his action in refusing to be a party to the spoliation of the health department. The executive committee of the citizens' union has also sent resolutions to Dr. Amster congratulating him on the stand he has taken and expressing their appreciation of his courage and wisdom in his struggle in behalf of the people of New York. Letters from various organizations and from physicians protesting against changes that threaten the efficiency of the health department continue to pour in on the mayor.

NORTH CAROLINA

Personal.—Dr. Samuel S. Coe has been selected as city physician of High Point, succeeding Dr. Thomas M. Stanton, who has resigned to enter the military service.

Health Officers Meet.—The North Carolina State Health Officers Association, composed of health officers, county, physicians, quarantine officers, medical inspectors of schools, and others interested in public health work met in conference in Pinehurst, April 15, under the presidency of Dr. Darius C. Absher, Henderson. The morning session was devoted to the discussion of quarantine and control of contagious diseases. The afternoon was occupied in the inspection of the state sanatorium for the treatment of tuberculosis, and in the evening, medical inspection of schools and the treatment of defective children were considered.

OHIO

Tuberculosis Items.—Final action on the proposition to establish a district tuberculosis hospital for the counties of Lorain, Erie, Huron, Ottawa, and Sandusky was taken at a meeting of the five boards and of the county commissioners held in Lorain, April 11.——At a conference of the governor with Dr. Stephen A. Douglass, superintendent of the Ohio State Sanatorium, Mount Vernon, and Mr. D. S. Creamer of the state board of administration held in Columbus, March 21, it was decided to erect additional cottages at the Mount Vernon institution, to care for the Ohio soldiers who may develop tuberculosis while in military service.

Personal.—Dr. Martin Friedrich, Cleveland, municipal medical expert, was seriously injured, March 30, in a collision between the automobile in which he was riding and a motor truck.——Dr. R. W. Cole, city epidemiologist of Akron, has left for his new post of duty as director of West Virginia's division of communicable diseases, public health, education, and statistics, with headquarters at Charleston.——Dr. Francis W. Firmin, Findlay, announces his retirement from the practice of medicine.——Dr. Thomas G. McCormick has been made local surgeon to the Chesapeake and Ohio system at Portsmouth, succeeding Dr. Orin W. Robe, who has resigned to enter military service.——Dr. Walter H. Rieger, Cleveland, for eight years surgeon for the Cleveland Railway Company, has been appointed house surgeon at the Manhattan Hospital, New York.——Dr. Herman S. Rhu, Marion, fractured his right arm and dislocated his right wrist while cranking his automobile, March 19.

Cincinnati

Personal.—Dr. Joseph W. Kirgan, Hyde Park, has resigned as a member of the state fish and game commission to take up oversea service under the auspices of the Y. M. C. A., as building secretary.——Dr. Emerson A. North has been superintendent of Longview Hospital, succeeding Dr. Frank W. Harmon, who resigned after thirty-seven years of service.——Dr. Frank H. Lamb has sailed for France to work with the American Red Cross Bureau of Infant Welfare.——Dr. Frank Scherrer, Norwood, sustained severe bruises in a collision between his automobile and a trolley car, March 26.——Dr. Walter E. List, assistant superintendent of the Cincinnati General Hospital, has been appointed acting superintendent during the absence of Dr. Arthur C. Bachmeyer, who is in military service.——Dr. E. A. Martin, assistant superintendent of the antituberculosis hospital, has been appointed acting superintendent of the institution.

PENNSYLVANIA

Personal.—Dr. Frederick W. Roberts, Plymouth, has brought suit for $50,000 damages against Hanover County and a local contractor on account of the death of his wife in an automobile accident several months ago.——April 4, the Clinton County Medical Society tendered a banquet to Dr. Luther M. Holloway, Salona, who has completed half a century of practice, and Dr. Francis P. Ball, Lock Haven, who has resumed practice.——Dr. John W. Wright has been reelected health officer of Erie for the thirty-third consecutive term.——Dr. J. C. Stern, Goldsboro, suffered a cerebral hemorrhage at New Cumberland, March 27.——Dr. Isaac Simon, Elizabethtown, while making a professional call recently, was shot and seriously wounded by the chief of police, who mistook him for a burglar.——The Lackawanna County Medical Society gave a banquet, March 20, in honor of its former president, Capt. Daniel A. Webb, C. A. M. C.——Drs. Simon S. Koser and Cynthia E. Koser, Williamsport, have started on a two-year trip to the British coast and Alaska.

Philadelphia

Personal.—Dr. James P. Hutchinson, in charge of the American Military and Red Cross Hospital No. 1 at Neuilly, has been honored with the French Cross for his hospital work in France. Dr. Hutchinson was a member of the staffs of the Pennsylvania and University Hospitals until he went to France in 1915 with the University of Pennsylvania Hospital Unit, of which the late Dr. J. William White was the head. Since Dr. Hutchinson has been in France, reports have reached here telling of his brilliant work for the wounded soldiers. The Cross of the Legion of Honor was bestowed on him a few weeks ago.——A dinner in honor of Dr. Samuel D. Risley, the father and dean of American ophthalmologists, who is retiring from public practice after forty-eight years of continuous service, was given, May 1, by the ophthalmologists of Philadelphia and other leading medical men. The testimonial meeting was presided over by Dr. G. Oram Ring. A silver loving cup was presented to Dr. Risley.

TEXAS

Baby Hospital Opened.—The Fort Worth Baby Hospital was formally opened, March 21. The hospital was built by the women's clubs of the city. Dr. Khleber H. Beall is resident physician of the institution.

State Society Meeting.—The annual meeting of the State Medical Association of Texas will be held in San Antonio, May 14-16. An exhibition of field hospitals will be given, May 13, and the entire meeting of the association will have a strong military trend as San Antonio is practically an armed camp.

VIRGINIA

Piedmont Tuberculosis Sanatorium Open.—The Piedmont Sanatorium for the treatment of tuberculous colored persons is now open and sixteen patients have been provided for in the institution. Forty beds are now available, and by fall it is expected that the capacity will be increased to eighty. This is a state institution and the nominal charge of $2 a week is made for each patient. This is the first institution in the state for the care of tuberculous colored patients. Dr. H. G. Carter is the active head of the sanatorium.

CANADA

Personal.—Lieut.-Col. Charles H. Gilmour, Toronto, who has been overseas for more than two years, and recently has been made chief surgeon at the Ontario Military Hospital, Orpington, is returning to Toronto.——Col. George E. Armstrong, Montreal, consulting surgeon to the Canadian Expeditionary Forces in England, is returning to Montreal.——Col. Charles A. Hodgetts, Ottawa, who has been overseas since the beginning of the war as Canadian Red Cross commissioner, is reported to have been given a position as deputy commissioner of medical services. Lady Perley, the wife of the Canadian High Commissioner in London, recently gave a reception in Colonel Hodgett's honor, at which he was presented with silver articles and an illuminated address by the Canadian Red Cross staff in London, England.——Col. Arthur E. Ross, Kingston, Ont., director-general of medical services, First Canadian Division, has recently been presented with the *Croix de Guerre* by the Belgian government.——Major William C. Laidlaw has been appointed deputy director of medical services at the Canadian Army Corps headquarters in France.——Major Claude E. Fortin is slated for chief of medical services in No. 10 (Winnipeg) Canadian Military District, succeeding Dr. Wellington H. Reilly, who is being transferred to Toronto for an important appointment.——Capt. Willis C. Connell has been serving for a year and a half in a British hospital, German East Africa. His home is at Prescott, Ont.——Capt. George F. Lewis, East View, Ont., went overseas in April, 1917, as medical officer. He served for a time with the Scottish Borders and then went to France. At present he is back in England and has charge of the men undergoing remedial treatment at Seaford, Sussex, England.——Lieut. Frank J. Elkerton, Chamberlain, Sask., who was for a time with the University of Toronto Base Hospital, has recently been appointed to the army medical board, Riseborough Barracks, Folkstone, England.——Capt. O. J. S. Little, Seaforth, Ont., has received an appointment at the Ravenscroft Hospital, Seaford, England.——Lieut. Alexander E. Macdonald, Brantford, Ont., is now serving as medical officer to a Toronto battalion of the first division.——Capt. Arthur C. Armstrong, M. C., C. A. M. C., medical officer of the Ross Military Hospital, Regina, Alta., has been elected a Fellow of the Royal Institute of Public Health of London. He has received both the Military Cross and the *Croix de Guerre*.——Capt. Oswald J. Day of the Royal Medicals, Toronto, recently received a bar to his Military Cross for leading bearers through the enemy barrages and effecting the recovery of wounded close to the German lines.——Dr. William E. Gallie, orthopedic surgeon, Toronto, has gone to England.——Capt. Willard E. Hodgins, Lucan, Ont., is in Wellington, India, in charge of a British hospital.——Capt. James D. Shields, Mount Albert, Ont., has been appointed to the pension board at Ottawa.——Dr. Basil C. H. Harvey, Toronto, '98, is now with No. 13 Base Hospital, Fort McPherson, Atlanta, Ga.

GENERAL

Sanitarians to Meet.—The Southeastern Sanitary Association will hold its annual meeting at Knoxville, Tenn., May 20 to 22. Dr. Charles E. Smith, Greenville, N. C., is secretary of the organization.

Meeting Indefinitely Postponed.—According to a notice sent out by the secretary, Dr. Collier F. Martin, Philadelphia, the American Proctologic Society has decided not to hold its meeting in Chicago, June 10 and 11. The society will probably not meet again until after the war.

Gifts and Bequests.—The following gifts and bequests have recently been announced:

House of Rest for Consumptives, $10,000, New York; New York Nursery and Child's Hospital, $20,000; General Memorial Hospital for the Cure of Cancer and Allied Diseases, $50,000; New York Asylum for the Blind, $5,000, by the will of Mrs. Margaret E. Zimmermann, of New York City.

Census of Drug Addicts in the United States.—In order to determine more accurately than has ever been done heretofore the number and distribution of drug addicts in the United States, the commissioner of internal revenue has requested every physician registered under the Harrison Narcotic Law to report the number of drug addicts for whom he prescribed or whom he treated, during the calendar year 1917. The information called for includes the number of male addicts of all ages, the number of male addicts between the ages of 21 and 31 inclusive, and the total number of female addicts of all ages. The questionnaire sends out calls for the name and address of every male addict between the ages of 21 and 31 inclusive, which represents practically all males within the draft age.

The term "drug addict" is defined as meaning "any person who is a confirmed user of opium or coca leaves, their salts, derivatives, or preparations." The information called for is said to be absolutely necessary for the use of the government in its work incident to the war, and strictest confidence is promised.

FOREIGN

Peruvian Hospital at Paris.—The Franco-Peruvian Hospital, maintained by the Peruvian colony in Paris, was formally inaugurated at 8 avenue d'Iéna in April. The hospital is for wounded and sick soldiers and is equipped with eighty beds.

Deaths in the Profession Abroad.—**R. Rivalta**, an Italian dermatologist and writer on his specialty, aged 46.——**S. Pansini**, professor of clinical medicine at the University of Naples, and one of the leading clinicians of Italy.——**A. Montuori**, instructor in physiology at the University of Rome and director of the Institute for physical education and experimental physiology.——**C. Vibert**, director of the laboratory for forensic medicine at the University of Paris and inspector general of the Morgue, author of numerous works on legal medicine and toxicology.

MEXICO, CENTRAL AND SOUTH AMERICA

Children's Sanatorium in Peru.—The Sociedad de Beneficencia Publica of Lima, Peru, has planned to construct a sanatorium for a colony of a thousand poor children, and donations have already been received insuring its realization.

Cumulative Index of the Revista Medica del Uruguay.—Our Montevideo exchange has just issued a single, comprehensive index for the twenty volumes of the *Revista* that have appeared to date. It forms a pamphlet of seventy-five pages.

Inter-University Gift of Casts.—The medical faculty of the University of Rio de Janeiro recently sent as a gift to the medical faculty of the University of Montevideo a set of wax models of some recent interesting cases in the dermatologic clinic.

Merging of Public Health Departments.—The *Revista Medica del Uruguay* mentions that the government of Paraguay is planning to combine the Asistencia Publica and the Departamento de Higiene under a single director-general and board of four members.

Milk Congress in Uruguay.—The minister of industries in Uruguay and the Consejo Nacional de Higiene organized in February at Montevideo a conference of persons connected with the dairy business and milk distribution, and the local medical and pediatric and the national veterinarian societies.

National Academy in Uruguay.—The government is now discussing the foundation of the Academia de Ciencias, Artes y Letras del Uruguay. It is proposed to have it composed of five institutes, one each for the medical sciences, the political sciences, the exact sciences, physics and nature and for arts and belles lettres.

Municipal Milk Distribution in Costa Rica.—The *Revista Medica del Uruguay* states that the medical faculty of the University of San José, Costa Rica, has appealed to the government for permission—which has been granted—for the municipality to assume charge of the distribution of milk, that is, to found an *expendio de leche*.

Data on Antityphoid Vaccination.—The Consejo Nacional de Higiene of Uruguay has sent a notice to all the physicians of the country instructing them, in sending in their notification of cases of typhoid fever, to specify whether the patient had been vaccinated against typhoid, and if so, to state the source of the vaccine, the number of injections, and the dates when they were made. The *Revista Medica* reproduces this notice with a word of comment on the value for the future estimation of antityphoid vaccination of data thus collected.

Conference on Typhus in Mexico.—The committee appointed at the recent national medical congress in Mexico to organize a conference on typhus, announces the date for Jan. 15 to 22, 1919, and urges collection of data by all the physicians of the country, giving a long list of questions to aid in compiling them for ready comparison, especially information in regard to the months when the typhus prevailed, the weather, rains, dust, association or precedence of other infectious diseases, conditions as to fomites, housing, etc. All communications and questions on the subject should be addressed to Dr. F. Ocaranza, San Juan de Letran, No. 19, Mexico, D. F. The complete list of questions and suggestions is given in Dr. Vasconcelos' Pagina Medica of *El Universal*, April 6, 1918.

PARIS LETTER

Paris, April 4, 1918.

Bread Made Directly from Wheat Grain

At a recent meeting of the Académie de médecine, Drs. Leprince and Lecoq called attention to a new method of making use of grain by a direct and rapid panification, a method proposed by Pointe, of the army commissary department. The principle of this new method of procedure is as follows: The unmodified grain, just as it is gathered, is cleaned mechanically under a current of water; following this it is made to absorb by maceration at 50 degrees the water necessary to its complete hydration, in the presence of a trace of alcoholic yeast, the development of which should prevent any harmful secondary fermentations. Then the wheat is crushed between grooved cylinders and depulped by being forced through a metal drum sieve which sifts out the bran from the starch and nitrogen which alone are suitable for human food. The paste thus prepared contains the water necessary for bread-making, and all that is necessary then is to add the normal quantity of yeast, and then to go on with the baking as under the ordinary conditions. The yield by this procedure attains to 75 to 76 per cent. of the quantity of the wheat employed, and it is to be expected that with perfection of the mechanical part of the method it will be possible to attain to 80 per cent. of extraction, which would correspond to about 115 kilograms of bread for 100 kilograms of the wheat. The bread so prepared is of a perfect quality. As for the bran, it is used to make cakes for the feeding of cattle.

Restrictions Concerning the Regulation Bread

In a previous letter was published the decree regulating the manufacture and sale of certain food commodities. A new decree has been issued regulating the manufacture and consumption of the regulation breads and flours. Gluten bread should consist of two parts of gluten; casein bread should consist of one part of casein to four of flour. The bread ticket calling for 100 grams of bread for current consumption entitles the holder to 50 grams of the *pain de régime*. The *pain de régime*, the flours *de régime* and other flour products containing cereals, legume flours, starch flour or any kind of flour, chocolate and cocoa must bear a label indicating the contained materials and the weight of each.

The Service of the American Red Cross

The American Red Cross merits a new tribute of recognition for the helpful rôle it has held since the beginning of the last offensive pertaining to the inhabitants of the departments of the Somme and the Aisne. At Montdidier, Noyon and Lassigny the American delegates have installed themselves to work on the reconstruction of the destroyed homes, restoring the land for cultivation. A number of trucks or lorries were placed at the disposal of the inhabitants to transport them to the rear, thus facilitating the railway service. The evacuated were directed to various hospital centers created in France by the Americans during the past two years. Furthermore, thousands of refugees have been fed and even hospitalized in Paris by the American Red Cross.

Saloons in the War Zone

The minister of finance has decreed that the wine shops at the front, transformed by order of the military authorities into hygienic establishments, need not pay any license fee on condition that the tenants in these establishments do not have, either in their cellars or in local storehouses, any alcoholic or spirituous liquors, and that they sign a declaration by which they agree to sell only hygienic or soft drinks.

LONDON LETTER

London, April 9, 1918.

More Physicians Wanted for the Army

The concentrated German attack on the western front has involved many casualties as well as some loss of medical men. The result is a demand for still more physicians for the army. The government has made an urgent appeal for physicians to come forward with offers of voluntary service to meet the pressure. Those now in the country who have relinquished their commissions are asked to rejoin. Secondly, the age for service has been extended and physicians under the age of 55 who are physically fit are asked to offer their services either at home or abroad. A physician responding to the appeal is promised that if he desires to return home or his presence is urgently needed to meet civil requirements his case will be reviewed at the close of the present crisis, and in any circumstances not later than six months after the date of joining, with a view to his being released, unless the ministry after considering the military and civil necessities of the time in consultation with the professional committee decides that this is impossible from a military point of view. The medical losses during the German offensive do not appear to have been great as regards personnel. The staffs of the advanced clearing stations were mostly safely evacuated, though in many this did not take place until the last moment, and, indeed, while some were in the firing line. As far as possible the sisters were sent back first, then the patients, and finally the medical men.

The Segregation of Neurasthenic Soldiers

Considerable controversy has arisen in consequence of a statement by Mr. Hodge, the minister of pensions, that a system of hospitals devoted to the treatment of neurasthenics invalided from the army is not the best plan. He wanted "neurasthenic cases mixed up with other cases so that the cheery chap might shed some of the sunshine of his presence over the others." Medical opinion does not agree with this. A neurologic conference at the War Office recommended that all soldiers suffering from a functional nervous disorder should be segregated in special hospitals, staffed by physicians specially trained for this work. It is true that some of the milder cases require only convalescent treatment in boarding houses or other homes, but the graver cases of shell shock and other nervous disorders require something more, and it has been found that treatment in special hospitals is successful, as many as 90 per cent. being rendered fit for civil work. Interesting testimony in favor of this treatment has been furnished by a letter sent to the committee of the Home of Recovery, Golders Green, by the patients under treatment. They state that they have benefited and in many cases recovered, and express satisfaction with the institution: "Our past experiences in general hospitals have taught us to appreciate being separated from other cases, especially from the so-called cheery man." They prefer the risk of an air raid to going into another hospital.

A Smaller Army Medical Advisory Board

The Army Medical Advisory Board has been reconstituted as follows: president, Lieut.-Gen. T. H. J. C. Goodwin, C.B., C.M.G., D.S.O.; members, Major-Gen. Sir B. E. Dawson, G.C.V.O., C.B.; Major-Gen. Sir B. G. A. Moynihan, C.B., F.R.C.S.; Col. W. H. Horrocks, C.B.; Col. Sir Robert Jones, C.B., F.R.C.S.; Lieut.-Col. Sir H. J. Stiles. The board has thus been considerably reduced in size. The only member of the old board retained is Colonel Horrocks, expert in sanitation. Sir Robert Jones, director-general of military orthopedic surgery for the British Isles, has during the war enhanced his already great reputation as an orthopedic surgeon, and has rendered considerable service to the army.

Marriages

Lieut. Jacques Henry Green, M. R. C., U. S. Army, Waterbury, Conn., on duty at the Department Laboratory, Southern Department, Atlanta, Ga., to Miss Agnes Sybil Lewis of New York City, at New York City, April 30.

Capt. Harold Ensign Bennett Pardee, M. R. C., U. S. Army, to Miss Dorothy Dwight Porter, at Hewlett, L. I., N. Y., April 15.

Lieut. Monroe Bradford Kunstler, M. R. C., U. S. Army, to Miss Francis Mandelbaum, both of New York City, April 29.

Lieut. Broox Cleveland Garrett, M. R. C., U. S. Army, Shreveport, La., to Miss Bessie Gray of Butler, Ala., on April 6.

James Samuel Goodrich to Miss Mary Adelaide Cleveland, both of Lexington, Ky., at Covington, Ky., April 19.

Lieut. Theodore Thomas Batson, M. R. C., U. S. Army, to Miss Aline Catharine Pinera, at New Orleans, April 21.

Edward James Rogers, Pittsford, Vt., to Miss Alma J. Hoykendorf of Scarsdale, N. Y., April 27.

William H. McKay to Miss Gertrude Selden Hicks, both of Bayside, L. I., N. Y., April 24.

Roll Harrison Markwith to Miss Ethel A. Davis, both of Columbus, Ohio, about April 21.

Deaths

Wallace R. Hunter, Erie, Pa.; University of Pennsylvania, Philadelphia, 1890; aged 52; formerly a Fellow of the American Medical Association; a member of the Medical Society of the State of Pennsylvania; acting assistant surgeon of the United States Public Health and Marine Hospital Service; attending surgeon to the Hanot Hospital, Erie, Pa.; a member of the medical staff of St. Vincent's Hospital; a member of the board of trustees of the state hospital at Warren; one of the founders of the Erie Municipal Hospital; died at his home, April 20.

William Arthur Moore, Binghamton, N. Y.; Columbia University, College of Physicians and Surgeons, 1885; aged 58; a Fellow of the American Medical Association; a fellow of the American College of Surgeons, and the American Academy of Medicine; surgeon to the Moore-Overton Hospital, Binghamton; surgeon of the Delaware and Lackawanna and Western Railroad; the Binghamton Traction Company, and the Delaware and Hudson Railroad; died at his home, April 26.

Lieut. Burt Jacob Asper, M. R. C., U. S. Navy, Chambersburg, Pa.; University of Maryland, Baltimore, 1911; aged 29; a Fellow of the American Medical Association; clinical assistant and assistant physician in the Sheppard and Enoch Pratt Hospital, Towson, Md., from 1912 to 1915; instructor of clinical pathology in the University of Maryland, 1912 to 1913; assistant physician to the Springfield State Hospital, Sykesville, Md., 1915-1917; surgeon on the U. S. S. *Cyclops*, which was lost at sea in April.

Died in the Service
LOST AT SEA ON THE CYCLOPS
Lieut. Burt Jacob Asper, M. R. C.,
U. S. Navy, 1888-1918

Henry Ebenezer Handerson, Cleveland, Columbia University, College of Physicians and Surgeons, 1867; aged 80; a member of the Ohio State Medical Association, and the Cleveland Academy of Medicine; formerly emeritus professor of hygiene and sanitary science in Cleveland College of Physicians and Surgeons; also an author of many medical subjects; died suddenly at the home of a friend, April 20, from cerebral hemorrhage.

Elmer M. Eckard, Peoria, Ill.; Rush Medical College, 1896; aged 45; formerly a Fellow of the American Medical Association; a member of the Illinois State Medical Society, and American Association of Railway Surgeons; formerly coroner of Peoria; chief surgeon of the Toledo, Peoria and Western Railway; and local surgeon for the Chicago, Peoria and St. Louis Railway; died at his home, April 21.

Edgar Fossin Green, State Sanatorium, Minn.; Medical College of the State of South Carolina, 1908; aged 43; a Fellow of the American Medical Association; formerly a member of the South Carolina State Medical Association; formerly of the state reformatory at St. Cloud, Minn.; died in Walker, Minn., April 23, from pulmonary tuberculosis.

William Alexander Ewing, New York City; Bellevue Hospital Medical College, New York City, 1869; aged 75; a Fellow of the American Medical Association; a member of the New York Academy of Medicine; formerly sanitary superintendent of the New York City Health Department; associate member of the surgical staff of the New York City Railway; died at his home, April 21.

Surg. Lieut.-Com. William Henry Rush, U. S. Navy, retired, Ardmore, Pa.; University of Pennsylvania, Philadelphia, 1873; aged 65; formerly surgeon on the training ship *Saratoga;* he was commissioned as assistant surgeon in the Navy, Feb. 13, 1877; three years later he became passed assistant surgeon, and was promoted to surgeon in 1894; died at his home, April 26.

Edith Anderson Van Dyke, Faribault, Minn.; Women's Medical College of Philadelphia, 1909; aged 37; assistant physician at the Faribault State Hospital for the Feebleminded, and a member of the school board; formerly a member of the staff of the Walker Sanitarium; died at the Faribault State School for Feebleminded, April 18, from pneumonia.

William Lomax Graves, Los Angeles; Medical College of Georgia, Augusta, 1859; a veteran of the Civil War; founder of the Farmers' Bank at Fresno; and helped to establish the National Bank of California; and formerly president of the Merchants National Bank; died at his home, April 7.

Daniel U. Wadsworth, Tulsa, Okla.; Medical Department of the University of the South, Sewanee, Tenn., 1898; aged 43; a member of the Oklahoma State Medical Association; formerly professor of surgery in the Mississippi Medical College; died at his home, April 13, from pneumonia.

James H. Craig, Mansfield, Ohio; Western Reserve University, Medical Department, Cleveland, 1885; aged 60; formerly a Fellow of the American Medical Association; a member of the Ohio State Medical Association; formerly city health officer; died at his home, April 10, from interstitial nephritis.

Charles G. Shipman, Oceanpark, Calif.; Rush Medical College, 1881; aged 61; a Fellow of the American Medical Association; formerly health officer of Santa Monica; director of the First National Bank of Ocean Park; died suddenly, April 10, in his office, from heart disease.

Charles Bowman Sturtevant, Manchester, N. H.; Dartmouth Medical School, Hanover, N. H., 1875; aged 67; a member of the New Hampshire Medical Society; formerly superintendent of schools of New Boston, N. H.; died at his home, April 12, from arteriosclerosis.

Lyle Barnes Rich, Willow City, N. D.; Johns Hopkins University, Medical Department, Baltimore, 1918, aged 26; died from typhoid fever in Base Hospital 18, December 18, 1917, while with the American Expeditionary Forces in France.

Guy Sumpter Waters, Prospect Station, Tenn.; Vanderbilt University Medical Department, Nashville, 1911; aged 37; a member of the Tennessee State Medical Association; died April 11, from a gunshot wound, self inflicted while despondent, it is believed.

Robert Shields Stedman, Brooklyn; Columbia University, College of Physicians and Surgeons, New York, 1889; aged 76; formerly a well known practitioner of Manhattan; retired for twenty-eight years; an inventor; died suddenly, April 13, from heart disease.

William Bratten Munford, Banks, Ore.; Kansas Medical College, Topeka, 1905; aged 44; formerly a Fellow of the American Medical Association; a member of the Oregon State Medical Association; died in Colorado Springs, April 10.

Oliver Allen McIntosh, Macomb, Ill.; Rush Medical College, Chicago, 1903; aged 53; formerly a Fellow of the American Medical Association; died at the Marietta Phelps Hospital, Macomb, Ill., January 8, from septic infection.

Willard Ammi Long, Lewiston, Mont.; Cooper Medical College, San Francisco, 1882; aged 59; formerly a Fellow of the American Medical Association; formerly health officer of Fergus County; died in Miami, Fla., about April 12, from acute dilatation of the heart.

William C. Wilkerson, Paris, Ky.; University of Louisville, Ky., 1881; aged 63; formerly a Fellow of the American Medical Association; formerly a practitioner of Little Rock, Ark.; died at his home, April 11, from cancer.

Jacob Stickel, Williamsport, Pa.; University of Michigan, Medical School, Ann Arbor, 1867; aged 73; formerly a member of the Medical Society of the State of Pennsylvania; died at the Williamsport Hospital, March 26.

John Boice Whittaker, Central City, Neb. (license, Nebraska, 1891); aged 73; a veteran of the Civil War; formerly coroner of Merrick County, and at one time Mayor of Central City; died at his home, April 5.

Richard H. Alfred, Dayton, Va.; Victoria University, Medical Department, Coburg, Ont., 1862; aged 83; formerly a member of the Medical Society of Virginia; died at his home, February 19, from senile debility.

H. Williams Smith, Crookston, Minn.; University of Minnesota, Minneapolis, 1897; aged 52; formerly a Fellow of the American Medical Association; died at his home, March 13, from heart disease.

George F. Brubaker, Springfield, Ohio; Medical College of Ohio, University of Cincinnati, 1893; aged 55; formerly president of the City Hospital staff; died at his home, April 10, from diabetes.

Charles Frank Ruch, Summithill, Pa.; Jefferson Medical College, Philadelphia, 1891; aged 48; a Fellow of the American Medical Association; died at his home, April 10, from rheumatic fever.

John A. Wheeler, Chicago; University of Michigan, Department of Medicine and Surgery, 1852; aged 90; was burned to death at his summer home in South Haven, Mich., April 28.

Alfred Stratford, Indianapolis; University of Louisville, Ky., Medical Department, 1871; aged 73; also a druggist; died at his home, January 20, from organic heart disease.

John Plutarch Avery, Indianapolis, Ind.; Bellevue Hospital Medical College, New York, 1866; aged 76; died at the Methodist Episcopal Hospital, Indianapolis, April 9.

Edwin Timothy Rucker, Richmond, Va.; Kentucky School of Medicine, 1877; aged 64; a Fellow of the American Medical Association; died at his home, April 9, from nephritis.

Anna Colby Smith Grigsby, Concordia, Kan.; Homeopathic Hospital College, Cleveland, 1883; aged 69; died at her home, January 8, from cerebral hemorrhage.

Charles Henry Wheeler, Fall River Mills, Calif; Eclectic Medical College, Cincinnati, 1889; aged 58; died at his home, April 11, from cerebral hemorrhage.

Emeline Tanner, Fairmont, Minn.; University of Michigan, Homeopathic Medical School, 1880; died in California, April 2, from heart disease.

J. Edwin Frazier, Tuolumne, Calif.; Louisville, Ky., Medical College, 1885; aged 62; died at Dr. Bromley's Sanitarium in Sonora, Calif., April 7.

Firmen C. Brooke, Chicago; Eclectic Medical College of Pennsylvania, Philadelphia, 1866; aged 75; also a druggist; died April 16.

Jane V. Myers, Philadelphia; Pennsylvania Medical College, Philadelphia, 1853; aged 87; died at her home, March 27.

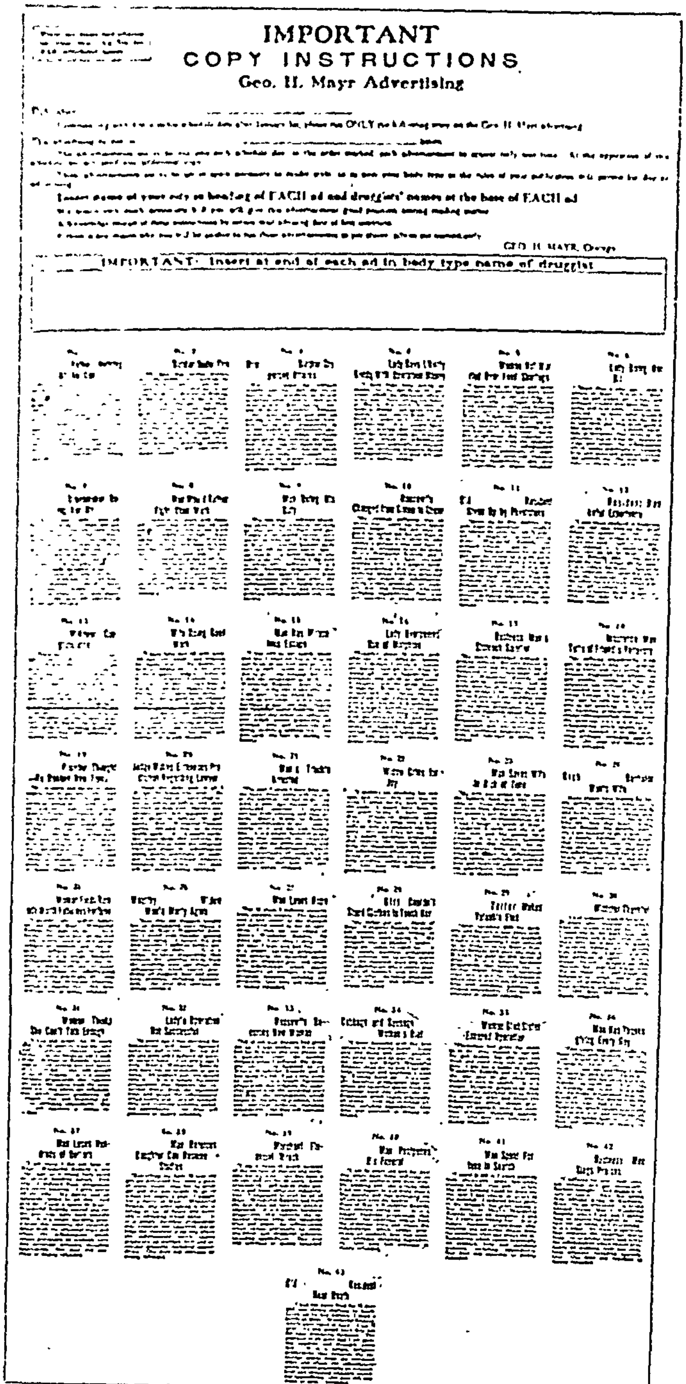
The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

MAYR'S WONDERFUL STOMACH REMEDY ADVERTISING

Also Mayr's Wonderful, Universal, Ready-Made Testimonials

"Mayr's Wonderful Stomach Remedy" has been the subject of more than one article in The Journal. Briefly, it may be said, for those who have forgotten this picturesque humbug,



IMPORTANT
COPY INSTRUCTIONS
Geo. H. Mayr Advertising

Insert name of your city in heading of EACH ad and druggists' names at the base of EACH ad

GEO. H. MAYR,

IMPORTANT: Insert at end of each ad in body type name of druggist

Reduced photographic reproduction of the "Copy Instructions" sent out to newspapers by George H. Mayr. The original was 16 inches by 32 inches. Notice that the newspapers are told (in black-faced type) to "insert name of your city in heading of each ad." This means, in effect, that the newspaper accepting this contract, agrees for a financial consideration knowingly to deceive and mislead its readers.

that it is a "patent medicine" adaptation of the old "fake gallstone" trick. The trick consists in administering a large dose of some such oil as olive, peanut or cottonseed, followed by a saline cathartic. The result of taking this combination is the passage of a number of soapy concretions which the victim is persuaded to believe are gallstones.

"It Removes Gall Stones and Shows Them to You" used to be the claim that appeared on the bottles of the "Wonderful Remedy." This disappeared after the federal Food and Drugs Act began to be a force for good. However, Mayr was not quite as shrewd as he might have been, for he continued to make claims in the trade package to the effect that his stuff was "a positive remedy for appendicitis" and "absolutely the best, most positive and permanent remedy for all stomach, liver and intestinal diseases." These claims, and some others, the government rightly charged were "false and fraudulent" and had been applied by Mayr "knowingly and in reckless and wanton disregard of their truth or falsity." Although Mayr was given an opportunity to prove that his claims were true, he pleaded guilty!

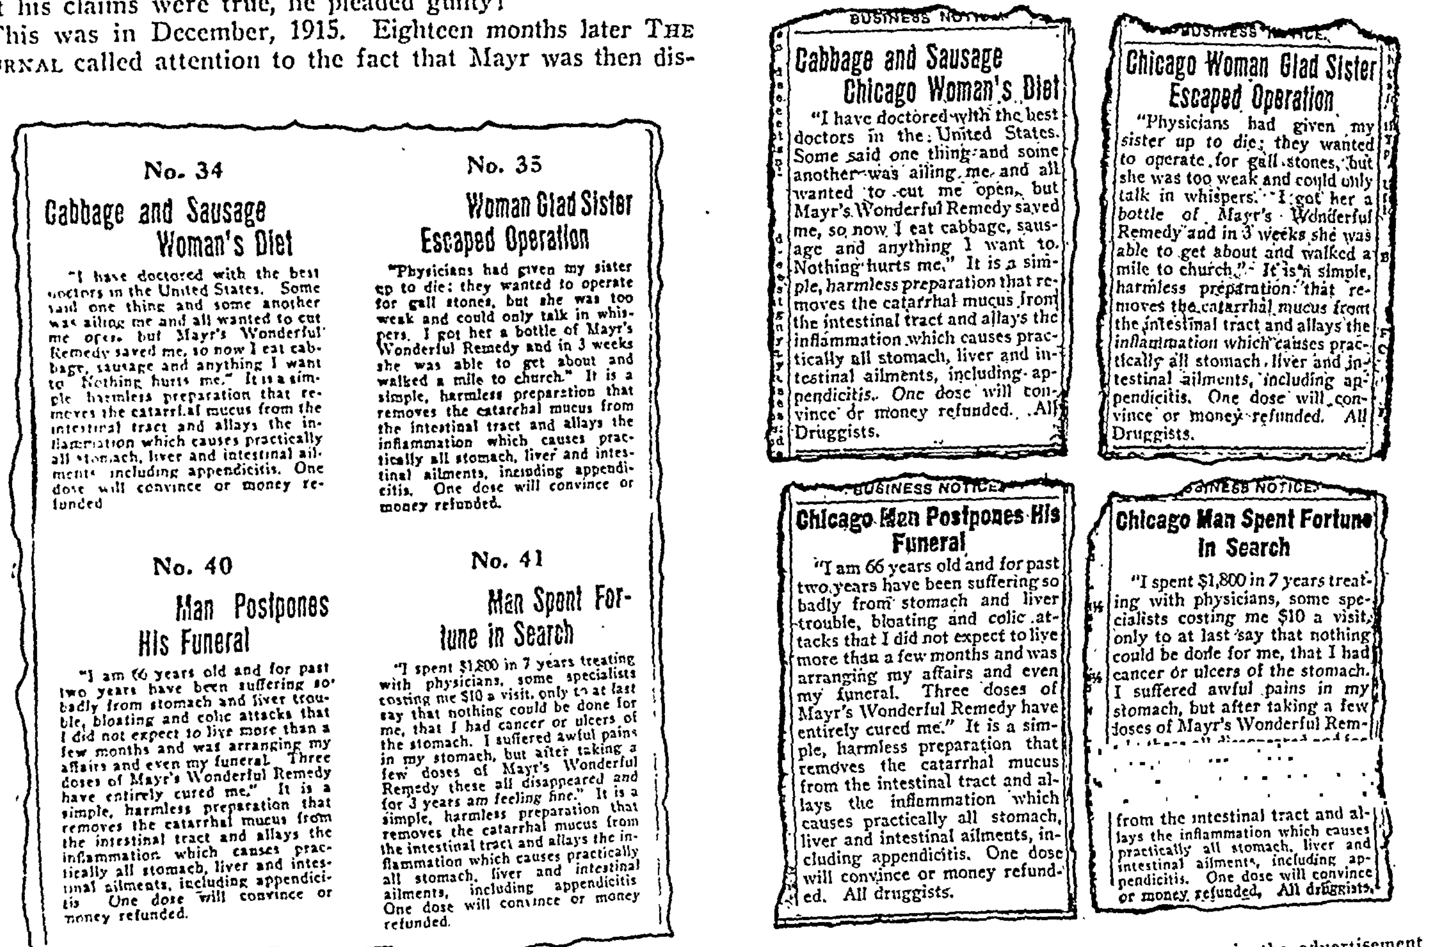
This was in December, 1915. Eighteen months later The Journal called attention to the fact that Mayr was then displaying in the windows of his Chicago store large placards containing not only essentially the same claims that the government had declared were fraudulent, and to which he had pleaded guilty, but claims that were even more false. Now, twenty-eight months later (May, 1918) Mayr still has painted over his store window the claim that his "Wonderful Remedy" is "the Only Known Cure for All Stomach, Liver and Intestinal Complaints"! Mayr's apparent contempt for federal authority may lie in the fact that the federal law cannot touch him for making false and fraudulent claims if he is careful to keep such claims off the trade package.

The present article, however, deals, not with his store-window advertising, but with his newspaper advertising. Mayr, it seems, is his own advertising agent and places his own "copy." In common with most "patent medicine" advertisers, his advertisements are of the testimonial type and the copy is frequently changed. Mayr's "Copy Instructions" to the papers are here reproduced in miniature. They consist, as will be seen, of forty-three pieces of advertising copy each with a heading in black-faced type, followed by what purports to be a quotation from a testimonial. Four of these pieces of copy (Nos. 34, 35, 40 and 41) are reproduced in such size as to be plainly readable. There are also reproduced four advertisements using the same "copy," each taken from copies of the Chicago *Examiner* of recent dates. It will be noticed that the copy furnished by Mayr differs from the advertisement as it appears in the papers, in that the latter has had inserted in the caption the name of the city in which the advertisements are published. For instance, the heading of Copy No. 35, as furnished by Mayr, reads:

"——— Woman Glad Sister Escaped Operation."

When this advertisement appears in, say, a Chicago paper, the newspaper carrying it obligingly inserts the name of the city, so that the heading reads:

"Chicago Woman Glad Sister Escaped Operation."



No. 34

Cabbage and Sausage Woman's Diet

"I have doctored with the best doctors in the United States. Some said one thing and some another was ailing me and all wanted to cut me open but Mayr's Wonderful Remedy saved me, so now I eat cabbage, sausage and anything I want to. Nothing hurts me." It is a simple harmless preparation that removes the catarrhal mucus from the intestinal tract and allays the inflammation which causes practically all stomach, liver and intestinal ailments including appendicitis. One dose will convince or money refunded

No. 35

Woman Glad Sister Escaped Operation

"Physicians had given my sister up to die: they wanted to operate for gall stones, but she was too weak and could only talk in whispers. I got her a bottle of Mayr's Wonderful Remedy and in 3 weeks she was able to get about and walked a mile to church." It is a simple, harmless preparation that removes the catarrhal mucus from the intestinal tract and allays the inflammation which causes practically all stomach, liver and intestinal ailments, including appendicitis. One dose will convince or money refunded.

No. 40

Man Postpones His Funeral

"I am 66 years old and for past two years have been suffering so badly from stomach and liver trouble, bloating and colic attacks that I did not expect to live more than a few months and was arranging my affairs and even my funeral. Three doses of Mayr's Wonderful Remedy have entirely cured me." It is a simple, harmless preparation that removes the catarrhal mucus from the intestinal tract and allays the inflammation which causes practically all stomach, liver and intestinal ailments, including appendicitis One dose will convince or money refunded.

No. 41

Man Spent Fortune in Search

"I spent $1,800 in 7 years treating with physicians, some specialists costing me $10 a visit, only to at last say that nothing could be done for me, that I had cancer or ulcers of the stomach. I suffered awful pains in my stomach, but after taking a few doses of Mayr's Wonderful Remedy these all disappeared and for 3 years am feeling fine." It is a simple, harmless preparation that removes the catarrhal mucus from the intestinal tract and allays the inflammation which causes practically all stomach, liver and intestinal ailments, including appendicitis One dose will convince or money refunded.

BUSINESS NOTICE.

Cabbage and Sausage Chicago Woman's Diet

"I have doctored with the best doctors in the United States. Some said one thing and some another was ailing me and all wanted to cut me open, but Mayr's Wonderful Remedy saved me, so now I eat cabbage, sausage and anything I want to. Nothing hurts me." It is a simple, *harmless preparation* that removes the catarrhal mucus from the intestinal tract and allays the inflammation which causes practically all stomach, liver and intestinal ailments, including appendicitis. *One dose* will convince or money refunded. All Druggists.

BUSINESS NOTICE.

Chicago Woman Glad Sister Escaped Operation

"Physicians had given my *sister up to die*; they wanted to *operate for gall stones*, but she was too weak and could only *talk in whispers*." I got her a *bottle of Mayr's* Wonderful Remedy and in 3 weeks she was *able to get about* and walked a mile to church." It is a simple, harmless preparation that removes the catarrhal mucus from the intestinal tract and allays the *inflammation which* causes practically all stomach, liver and intestinal ailments, including appendicitis. One dose will convince or money refunded. All Druggists.

BUSINESS NOTICE.

Chicago Man Postpones His Funeral

"I am 66 years old and *for* past two years have been suffering so badly from stomach and liver trouble, bloating and colic attacks that I did *not expect* to live more than a few *months* and was arranging my affairs and even my funeral. Three doses of Mayr's Wonderful Remedy have entirely cured me." It is a simple, harmless preparation that removes the catarrhal mucus from the intestinal tract and allays the inflammation which causes practically all stomach, liver and intestinal ailments, including appendicitis. One dose will convince or money refunded. All druggists.

BUSINESS NOTICE.

Chicago Man Spent Fortune In Search

"I spent $1,800 *in 7 years* treating with physicians, some specialists *costing me* $10 a visit, only to at last say that nothing could be done for me, that I had cancer or *ulcers of the stomach*. I suffered awful *pains in my* stomach, but after taking a few doses of Mayr's Wonderful Rem-

from the intestinal tract and allays the inflammation which causes practically all stomach, liver and intestinal ailments, including appendicitis. One dose will convince or money refunded, All druggists.

Photographic reproduction (reduced) of four pieces of Mayr's advertising *copy* (on the left) and the same copy set up in the advertisement form as it appeared in some recent issues of the Chicago *Examiner*. Thus the "*Chicago* Woman" who had "doctored with the best doctors in the United States," all of whom "*wanted to cut me open*," would be a *St. Louis woman*, or a *Kalamazoo* woman, or an *Oshkosh* woman if the papers published in those cities could be hired to print the advertisements.

And the "*Chicago* Woman" would be a "*St. Louis* Woman," a "*Kalamazoo* Woman" or an "*Oshkosh* Woman" if papers published in those cities could be hired to print the Mayr advertisements. It will be noticed by again referring to the "Copy Instructions," which are reproduced in miniature, *that* the newspapers are told, in black-faced type, to "Insert *name* of your city in heading of EACH ad. . . ."

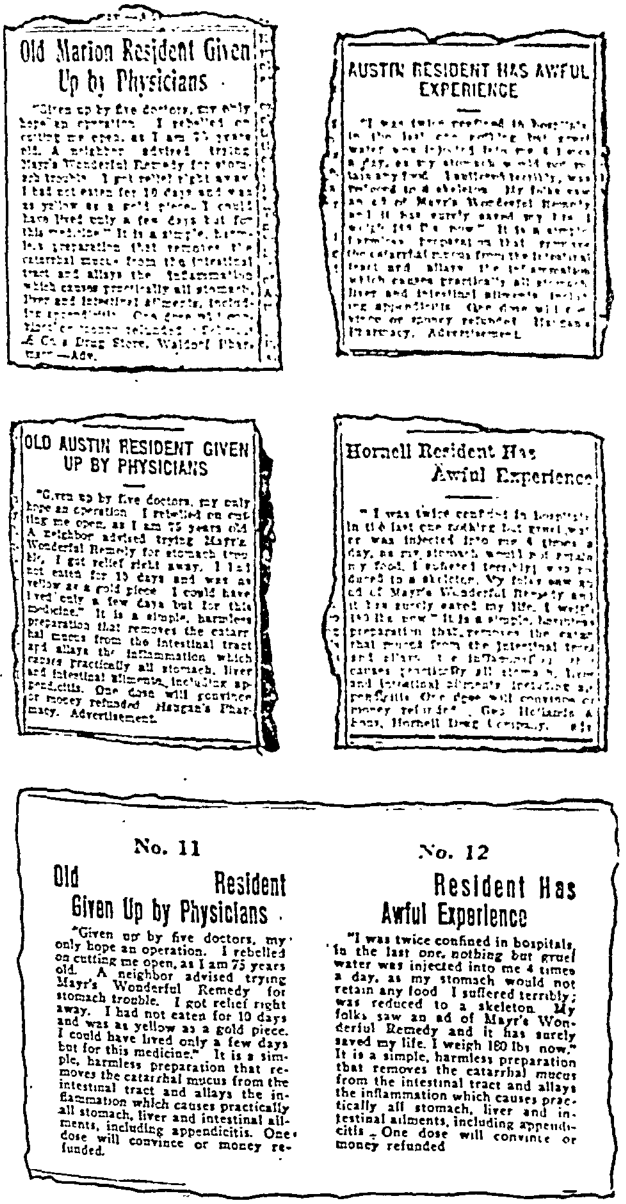
Was there ever a more cynical disregard for the elemental principles of common truthfulness and decent business methods? Here are what purport to be forty-three *testimonials* from people who have taken Mayr's Wonderful Stomach Remedy and received benefit or cure. The newspaper *accepting* this copy becomes frankly *particeps criminis* with Mayr in his lying campaign. Copy instructions alone *prove* that each of these forty-three testimonials is a distinct and separate lie and that these lies are to be multiplied by as many times as there are papers which will publish the advertisements.

Notice the testimonials in Copy Nos. 11 and 12: "Old ——— Resident Given Up By Physicians" and "——— Resident

Has Awful Experience." Just notice our reproductions from the Marion (Ohio) *Daily Star*, the Austin (Minn.) *Daily Herald* and the Hornell (N. Y.) *Evening Tribune-Times*. Here we read that the "Old Austin Resident," the "Old Marion Resident" and the "Hornell Resident" have been "Given Up By Physicians" or had "Awful Experiences."

It is entirely in keeping with the type of ethics shown by Mayr in his advertising that he should have attempted to capitalize the present national situation:

"———— Soldier Under Fire."
"How ———— Soldier Dispersed Attacks."
"———— Lady Buys Liberty Bonds With Operation Money."
"———— Woman Not Worried Over Food Shortage."



Old Marion Resident Given Up by Physicians

AUSTIN RESIDENT HAS AWFUL EXPERIENCE

OLD AUSTIN RESIDENT GIVEN UP BY PHYSICIANS

"Given up by five doctors, my only hope an operation. I rebelled on cutting me open, as I am 75 years old. A neighbor advised trying Mayr's Wonderful Remedy for stomach trouble. I got relief right away. I had not eaten for 10 days and was as yellow as a gold piece. I could have lived only a few days but for this medicine." It is a simple, harmless preparation that removes the catarrhal mucus from the intestinal tract and allays the inflammation which causes practically all stomach, liver and intestinal ailments, including appendicitis. One dose will convince or money refunded. Haugan's Pharmacy. Advertisement.

Hornell Resident Has Awful Experience

No. 11

Old Resident Given Up by Physicians

"Given up by five doctors, my only hope an operation. I rebelled on cutting me open, as I am 75 years old. A neighbor advised trying Mayr's Wonderful Remedy for stomach trouble. I got relief right away. I had not eaten for 10 days and was as yellow as a gold piece. I could have lived only a few days but for this medicine." It is a simple, harmless preparation that removes the catarrhal mucus from the intestinal tract and allays the inflammation which causes practically all stomach, liver and intestinal ailments, including appendicitis. One dose will convince or money refunded.

No. 12

Resident Has Awful Experience

"I was twice confined in hospitals, in the last one, nothing but gruel water was injected into me 4 times a day, as my stomach would not retain any food. I suffered terribly; was reduced to a skeleton. My folks saw an ad of Mayr's Wonderful Remedy and it has surely saved my life. I weigh 160 lbs now." It is a simple, harmless preparation that removes the catarrhal mucus from the intestinal tract and allays the inflammation which causes practically all stomach, liver and intestinal ailments, including appendicitis. One dose will convince or money refunded

Photographic reproduction (reduced) of advertising copy Nos. 11 and 12 together with reproductions of four advertisements from the Marion (Ohio) *Daily Star*, the Austin (Minn.) *Daily Herald* and the Hornell (N. Y.) *Evening Tribune-Times*, respectively. One wonders whether these newspapers have ever heard of the movement toward "truth in advertising"!

Possibly Mr. Mayr, having found that, so far as his store-window claims are concerned, he can, figuratively speaking, put his thumb to his nose at Uncle Sam, may have figured that he is equally free to continue his present lying campaign in the newspapers. If this is Mayr's theory, we are of the opinion that it is likely to be revised.

Correspondence

PROTECTION AGAINST LICE

To the Editor:—In The Journal, April 27, 1918, p. 1247, your London correspondent mentions some important facts respecting the role of the louse as the cause of trench fever; and, from what is there said, it would appear that, while the typhus disease is conveyed by the bite of the louse, trench fever is the result of an infection from the other end of that insect. Indeed, it would seem that man, proud man, has been reduced to the last stage of physical degradation by being trodden on, preyed on, and his comfort, health and life placed in jeopardy by the excrement of this abhorred parasite—the indignity being literally rubbed into him in a double sense; and, in this connection, the means of prevention are of first importance; and as they appear to be simple and available, I now take the liberty of speaking on this subject.

In the accounts given of John Howard and his work in visiting English jails, prisons and lockups, where typhus was actively present, it is mentioned that he always bathed, and changed his clothes after visits to such centers of infection; but this sanitary recourse cannot have been the whole story, for it is not said that he ever suffered in bodily comfort or health from such extended benevolent ministrations.

The fact is known that the courts, where prisoners from such centers of virulent infection were tried, were sometimes broken up by the death from typhus of the judges and minor officials; but precisely how this fatal communication occurred has not been altogether made clear.

An early professional experience that I had in connection with service in a public institution may throw some light on the question; for, in dealing with emergency patients picked up in the streets, some of whom proved lousy, a very unfavorable prognostic sign was found in the decamping of lice from such a body—the probable explanation being that these parasites, being sensitive to temperatures, felt the coming chill as circulation ceased, and promptly departed, seeking lodgment elsewhere. That they are known to be capable of a considerable migration may explain the infection of judges on the bench.

In my personal experience as a country youth, it was common practice to smear with grease the arms and legs as a protection against wood ticks, chiggers, sand flies, lice, etc.; and, when well applied, this was an effective safeguard against such vermin. It is accordingly suggested that Howard must have known and used such means of defense; but he may not have been willing to let it be generally known through fear of the coarse ridicule too often visited on benefactors of the human race.

Some years ago when war broke out in the Balkan states and pandemic typhus appeared, a contingent of physicians from this country went over to lend their aid, and some of them died of that infection. In commenting on this sad dénouement even The Journal spoke of them as martyrs to science, an opinion I could not share; for, though it may seem ungracious to say so, they appeared to me rather as the victims of ignorance through not knowing the means of prophylaxis.

Any form of sticky fat that does not melt freely at body temperature seems effective, the explanation presumably being that the spiracles of the insect are clogged, and death by suffocation follows; while the newly hatched young die likewise when attempting to feed, even if the nits are not destroyed, as such.

It was recently stated publicly here, by a medical officer lately returned from France, that gasoline is not effective in dealing with body lice, and an explanation that occurs is that they are rather benefited by its solvent action in clearing the breathing pores of possible obstruction. It has been claimed, also, that silk underwear is useful, as the fiber is said to afford no foothold to the louse in its effort to pierce the epidermis; but an oiled fabric of any kind would be very likely to prove equally effective, if the contention as to the indicated physical difficulty of the insect is well based.

A suggestion of fatty agents for protective bodily inunction would be a combination of castor oil and tallow, sticky and substantial, not expensive, and which in use would probably meet all the leading indications. Petroleum products may be found equally effective.

George Homan, M.D., St. Louis.

MEDICAL SCHOOL RECOGNIZED IN NEW YORK

To the Editor:—Table D, published in The Journal, April 13, indicates that the University of Virginia Department of Medicine is not a registered medical school in New York and New Jersey.

With regard to New Jersey, I wish to state that this board dropped the University of Virginia without consulting or even notifying me. The first intimation I had of its action was a letter received a week ago from one of our graduates informing me that this board had declined to allow a graduate of this school to take the licensure examination until he had spent an additional year of study in one of their registered schools. A letter from the secretary of the New Jersey board informs me that their list of acceptable schools is the New York list.

With regard to New York, the University of Virginia was registered with the regents until the spring of 1917. It was then transferred to their list of "accredited" schools for the sole reason that at that time we were not ready to agree to the absolute prohibition of entrance conditions on certain parts of our two year college requirement. During the fall and winter of 1917 we had an extensive correspondence with this board, urging that special provision be made for entrance conditions in special cases. Our suggestions received careful and courteous consideration by the board, but the regents finally declined to change their rule, absolutely forbidding any entrance conditions whatever.

Although the University of Virginia was and still is strongly of the opinion that this is an unwise and unnecessary measure—and the editorial comment as well as Dr. French's paper shows that we are not alone in this opinion—still it was clear that it would be unfair to our school and its graduates to have them excluded from practice in the state of New York. We therefore voted in January to abolish all entrance conditions hereafter. When this action was reported to the regents, they restored the University of Virginia to their list of registered schools, Jan. 31, 1918.

I regret that my inadvertent failure to notify the Council on Medical Education of this action of the regents has led to an erroneous statement which can be only imperfectly corrected. The Journal, of course, is in no way to blame for the mistake.

Theodore Hough, Charlottesville, Va.
Dean, Department of Medicine, University of Virginia.

[Comment.—Table D is based on official reports received from the various state medical boards. Since its publication, however, New York has notified us that the University of Virginia Department of Medicine should not have been included among the medical schools not fully recognized by the Board of Regents, thus confirming Dean Hough's statement.—Ed.]

PEANUTS AS FOOD

To the Editor:—I have read with a great deal of interest the food articles appearing in The Journal in Current Comment. March 23, special reference was made to peanuts, and on page 1004, April 6, to the yield of food per acre. This comment referred especially to corn, and stated that 35 bushels of corn per acre produce 150 pounds of protein and more than 3,000,000 units of energy. Further reference was made to the soy bean.

The peanut is unusually interesting for several reasons: First, it produces an average of 1,000 pounds of nuts per acre, containing 2,000,000 units of energy and approximately 220 pounds of protein. If the peanuts are properly handled, they will produce about 500 pounds of peanut flour, which contains 44 per cent. of protein and 7.5 per cent. of fat. This peanut flour blends readily with all flour and flour substitutes as well as corn meals, and is now an official substitute for flour in Florida. When this thousand pounds of peanuts are crushed, they produce 300 pounds of edible oil. In addition, there is a yield per acre of hay, testing 13 per cent. protein, which is a most excellent food for live stock, which gives an additional 130 pounds of protein per acre.

The peanut can be grown all over the South, is one of the surest crops, and can be produced in less time, with less labor, at smaller cost than most of the staple crops. Every farmer in the South knows how to grow peanuts, and the South in 1919 could easily put in 10,000,000 acres. This would produce 3,000,000,000 pounds of fat, which would take care of the fat shortage, and 5,000,000,000 pounds of peanut flour, running 44 per cent. protein and 7.5 per cent. fats.

Allowing 4 ounces of protein per day for an adult under the most strenuous working conditions, this production could supply all the protein consumed by 24,000,000 adults under the most strenuous conditions for 365 days. This crop can be produced in four months from the time of planting, and the land on which it was planted can be planted with small grains during the other eight months. Without doubt, the peanut will produce more food for man and beast in less time, with less labor and less acreage than any other known crop. This is one crop than can be made to take care of both the meat and fat shortage.

We are manufacturers of peanut flour on a commercial scale, and it is being widely used throughout the South.

B. F. Williamson, Gainesville, Fla.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

COTARNIN HYDROCHLORID

To the Editor:—Please describe the action of cotarnin hydrochlorid and indications for its use. Is it derived from opium?

W. E. Smith, M.D., *Rossford, Ohio.*

Answer.—In New and Nonofficial Remedies, 1918, p. 83, cotarnin is stated to be an artificial alkaloid derived by oxidation from narcotin, by a process analogous to the derivation of hydrastinin from hydrastin (which again differs from narcotin only by an additional OCH_3 group). Cotarnin hydrochlorid is marketed as "stypticin," the phthalate as "styptol." Cotarnin is used systematically mainly against uterine hemorrhage; especially in menstrual menorrhagia, endometritis, and congestive conditions. It is ineffective against postpartum hemorrhage or bleeding from gross anatomic lesions, and probably also against hemorrhage in other internal organs. The clinical reports in its favor are often superficial and sometimes contradictory, but seem to justify the preceding statements. No satisfactory explanation for these actions has been established. The most probable is the (unproved) assumption of a special constrictor action on the uterine vessels. The circulatory changes observed in experiments are small and probably do not occur in the therapeutic use. The uterine stimulation observable on excised uteri probably does not occur in life. Local application of cotarnin in substance or concentrated solution has a direct vasoconstricting effect and is used in tooth extractions, epistaxis, etc.

Typhus Lesions.—E. Fraenkel relates that the roseola patches of typhus can be brought out again by applying a tourniquet to the limb, week after week, up to the tenth week after defervescence. In his communication on the subject in the *Münchener medizinische Wochenschrift*, No. 40, he remarks that probably the similar changes found in and around the arteries of the internal organs persist in the same way long after defervescence. (From abstract in *Nederlandsch Tijdschrift*.)

WISCONSIN: Milwaukee, June 25. Sec., Dr. J. M. Dodd, Ashland.

Vermont February Examination

Dr. W. Scott Nay, secretary of the Vermont State Board of Medical Registration, reports the oral and written examination held at Burlington, Feb. 12, 1918. The examination covered 12 subjects and included 90 questions. An average of 75 per cent. was required to pass. Six candidates were examined, all of whom passed. One candidate was licensed through reciprocity, and 1 candidate was granted a reregistration license. The following colleges were represented:

College PASSED	Year Grad.	Per Cent.
Rush Medical College	(1917)	89.6
Tufts College Medical School	(1918)	91.1
Vanderbilt University	(1917)	90.1
University of Vermont	(1917)	88.1, 88.3
McGill University	(1910)	88.1

College LICENSED THROUGH RECIPROCITY	Year Grad.	Reciprocity with
University of Vermont	(1902)	New Hamp.

Book Notices

THE IMMEDIATE CARE OF THE INJURED. By Albert S. Morrow, A.B., M.D., Clinical Professor of Surgery in the New York Polyclinic. Third edition. Cloth. Price, $2.75 net. Pp. 356, with 242 illustrations. Philadelphia: W. B. Saunders Company, 1917.

The recent great impetus to the study of the care of the sick and injured has been met in part by the formation of countless classes in first aid. An experience of several years as a teacher of such classes has impressed the reviewer with the desirability of a textbook that would give in greater detail than does the little Red Cross Manual (Women's Edition) the essential facts of the normal anatomy and physiology of the body in conjunction with a discussion of the cause and management of various pathologic changes with which the lay first aider might be expected to cope. Dr. Morrow's book appears to fill this need admirably. The first part is devoted to a consideration of the anatomy and physiology of the human body. The structure (gross and microscopic) and function of the various tissues and organs are presented in a clear, concise manner. The second part is a general discussion of bandages and slings, dressings, practical remedies, such as hot packs, enemas and counterirritants, and of antiseptics and disinfectants. In the third part the questions of how to act and what to do in emergencies are taken up in detail. Here the facts and principles described in the preceding parts are applied to specific cases. The book is well illustrated While intended for the instruction of those who are not trained in medicine, it is probable that there are few physicians who could not peruse its pages with benefit.

Freezing Is an Accident; Also, Heat Stroke

(State ex rel. Virginia & Rainy Lake Co. v. District Court of St. Louis County et al. (Minn.), 164 N. W. R. 585, State ex rel. Nelson v. District Court, Ramsey County, et al. (Minn.), 164 N. W. R. 917)

The Supreme Court of Minnesota says that the direct authorities upholding findings in freezing cases are few. That freezing is a personal injury within the meaning of the workmen's compensation act, the court says, in the first of the foregoing two cases, is not open to question. Nor is it to be questioned that within the statutory definition it is an "unexpected and unforeseen event," or that it is an event "producing at the time injury to the physical structure of the body." The difficult question is whether the requirement that the event be one "happening suddenly and violently" excludes it. Freezing comes suddenly and violently as distinguished from gradually and naturally or in ordinary course. In common talk a sudden or violent death is one occurring unexpectedly and not naturally or in the ordinary course of events. In some such sense the words are used in the statute. Their effect is not to exclude from accidental injuries all except such as result from physical force applied from without. A fair construction of the statutory definition does not exclude freezing, and the court holds that it is a personal injury caused by accident within the meaning of the act.

The freezing involved in the first case occurred in January, 1916. The workman was employed by the Virginia & Rainy Lake Company as a swamper in the woods in the northern part of St. Louis County. He was cutting and handling timber and making roads for swamping. He used an ax, handled the timber with his hands, and they came into contact with the snow. The weather was severely cold. He was 4 or 5 miles from camp. There were no facilities for warming. The building of fires was not permitted. It was not questioned that the employee received his injury, a freezing of his thumb which resulted in its amputation, in the course of his employment. But the court also thinks that the evidence fairly sustained the view that the character of his work subjected him to a risk of freezing not shared by the generality of the community and sustained a finding that the freezing arose out of the employment. It was not enough that it occurred while work was in progress. It must have arisen under such circumstances that a causal connection was traceable between the employment and the freezing, and the freezing must be more than a consequence, shared by the community in general, of exposure to cold.

In the second case, the court holds that the evidence sustained a finding that the injury to relator Nelson, a janitor, was one "arising out of his employment" within the workmen's compensation act, when, while shoveling snow from the sidewalks about a building in severely cold weather, he froze the great toe, which resulted in the amputation of the leg.

A similar question, the court says, is presented by cases involving sunstrokes or heat strokes, which are the subject of review in *State ex rel. Rau v. District Court*, 164 N. W. R. 916, a heat stroke case, wherein the evidence was held such as to authorize a finding that the injury arose out of the employment.

Current Medical Literature

AMERICAN

Titles marked with an asterisk (*) are abstracted below.

American Journal of Diseases of Children, Chicago

April, 1918, **15**, No. 4

1 *Familial Splenomegaly. *C. de Lange and J. C. Schippers*, Amsterdam, Holland.—p. 249.
2 *Hydrocephalus of Poliomyelitis. *J. G. Regan, Brooklyn.*—p. 259.
3 *Experience with Vaccine in Prevention of Whooping Cough. F. Vander Bogert, Schenectady, N. Y.—p. 271.
4 Abdominal Injury Due to Blunt Force; Difficult Diagnosis. H. P. De Forest, New York.—p. 272.

1. **Familial Splenomegaly.**—Two cases which presented the clinical picture of splenomegaly of Gaucher's type were examined by De Lange and Schippers. There were seven children in this family. The enlargement of liver and spleen was already noticed in one child when 4 years old; in the other when 2 years old. There is every reason to believe that the disease in question is congenital in origin. The Wassermann reaction was, in the beginning, slightly positive. On later examination, carried out by another serologist, the test was slightly positive in the case of one girl, negative in that of the other child; on third examination, performed by the same serologist, the reaction proved negative in both instances. The first examination of the father's blood showed a slight leukopenia; the second and third were practically normal, although somewhat low; a relative lymphocytosis was always present. The other members of the family, the mother, paternal grandmother, maternal grandfather and maternal grandmother were negative. Based on the data obtained no other clinical diagnosis but splenomegaly of Gaucher seemed possible.

2. **Hydrocephalus of Poliomyelitis.**—According to the type of symptoms and the time they persist, Regan has found it advisable to divide the hydrocephalus of poliomyelitis into the following forms: 1. That of the *onset* (including the preparalytic and early paralytic stages). 2. That persistent after the first week of the disease and comprising three varieties: (*a*) a mild form commonly encountered in which there is only a slight increase in fluid and in which symptoms are practically absent; (*b*) a more severe form comprising various degrees, in which there are distinct signs of pressure; (*c*) a very severe type, more or less insidious in onset, indefinite in physical signs, and associated with evidences of progressive emaciation. Symptoms of these various types are described and suitable case reports are included to amply explain these descriptions. Regan is convinced that Macewen's sign provides a definite means by which these symptoms of hydrocephalus may be easily recognized and suitable treatment by rachiocentesis instituted, and therefore its employment in the routine physical examination of a patient with poliomyelitis is of the utmost importance.

3. **Vaccine in Prevention of Whooping Cough.**—At the Children's Home in Schenectady, one of the forty-six inmates developed whooping cough on or about Nov. 27, 1917, but because of failure of diagnosis was allowed to mingle for nearly a week with other children, after which he was isolated in a separate building. It was later learned that during this time he was known to have whooped and vomited. An epidemic of the disease was well under way in the city at the time, and several of the whooping cough patients had been attending the school to which the children of the home were sent daily. Seven weeks after the development of the case, there were nearly 400 records of pertussis at the city health department. Dec. 3, 1917, thirty-one who gave no record of having had whooping cough were inoculated, each with 50 million plain pertussis vaccine (stock). No reactions were noted, but one child complained of a sore arm. Up to the present time (Jan. 24, 1918) not a single case has developed in the home. The original case was given one dose of vaccine immediately after the diagnosis was made and ceased whooping at the end of one week. The vaccine was *not* repeated.

14 *Superiority of Inoculations with Mixed Triple Vaccine (B. Typhosus, B. Paratyphosus A, and B. Paratyphosus B). W. C. Davison, Philadelphia.—p. 437.
15 *Study of Metabolism of Asthma. E. Zugsmith, Pittsburgh, and M. Kahn, New York.—p. 510.
16 *Conglomerate Tubercle and Combined Degeneration of Cord as Complications of Visceral Tuberculosis. P. Bassoe, Chicago. —p. 519.
17 *Pituitary Gland in Epileptics. J. F. Munson, Sonyea, N. Y. —p. 531.
18 *Intravenous Serum Treatment of Epidemic Cerebrospinal Meningitis. W. W. Herrick, Camp Jackson, S. C.—p. 541.

14. **Superiority of Inoculations with Mixed Triple Vaccine.**—Davison carried out a series of inoculations in a number of men and rabbits with vaccines prepared from cultures of one, two or all three of the bacilli (*B. typhosus, B. paratyphosus* A and *B. paratyphosus* B), varying the order of their introduction in the successive immunizations of different groups of rabbits. The details of all the experiments are given in full and the results are discussed. The following conclusions bearing on the practical problem of prophylactic inoculation in man against the typhoid-paratyphoid group of organisms stand out as possessing paramount importance: 1. When a mixed vaccine is used the immunity obtained for each of its constituent bacilli is at least as good as, and very often greater than, that obtained against *any* one of

these organisms when it is employed alone in the same dosage for a first immunization. 2. When single vaccines are employed in succession and the immunizations are carried out independently, the response is greatest to that vaccine which is introduced first. To the later immunizations with other micro-organisms the specific response is almost always less intense. It has associated with it, however, as a secondary result the production of a new rise of variable extent in the agglutinin titer of the serum of the bacillus of the first immunization.

15. **Metabolism of Asthma.**—Asthmatic individuals seem to suffer from a condition of tissue suboxidation. Whether this is due to the lack of oxygen induced by the functional failure of the pulmonary system, or whether the suboxidation is the result of the causative factor of the disease and is, perhaps, the etiologic factor in the production of the spasmodic seizure, cannot be at the present time decided. If it were possible to study the metabolism of a patient who did not suffer from asthma, but who had the etiologic factors present that may induce asthma, as, for example, an anaphylactic state that is present without the asthma, this point might be cleared up. The neutral sulphur fraction (consisting of the various unoxidized sulphur derivatives, like taurine, taurocarbamic acid, cystin, sulphocyanates, the oxyproteic and uroferric acid, the volatile sulphids, etc.) increase shows this lack of oxidation. This seems to agree with the findings of various observers who noticed a decrease of tissue oxidation in dyspneic animals. Zugsmith and Kahn find also that the creatinin output is low, thus indicating a lessened tissue oxidation, for, according to Folin and others, the creatinin output depends only on the endogenous katabolism of the body. While they did not notice that there was a lessened excretion of urea in urine, they found that the observation of Colosanti that there was a decrease in tissue breakdown during dyspnea, held true in human beings suffering from asthma. It is not true, however, that secretion of urine stops during the dyspneic attack, for in one case the secretion of urine seemed to be stimulated during the spasm, at least the patient voided urine frequently.

16. **Cord Degeneration and Visceral Tuberculosis.**—Bassoe reports two cases. Case 1.—Conglomerate tubercle in midthoracic region: Onset with epigastric paresthesia, then girdle pains, numbness and weakness of legs, finally picture of transverse lesion. Much pus in urine, but no pulmonary symptoms. Tuberculosis not recognized during life. Death seven months after onset. Necropsy: Pulmonary and genito-urinary tuberculosis. Conglomerate intramedullary tubercle at level of seventh thoracic vertebra. Numerous tubercle bacilli in sections from cord. Case 2.—Man of 46 years with history of stroke causing right hemiplegia five years before death. Only partial weakness left behind. Later, pain and weakness of right side, followed by paraplegia and sphincter disturbance. Increased tendon reflexes and Babinski sign. No pulmonary symptoms and only slight physical signs. Necropsy: Chronic pulmonary and pleural tuberculosis. Atrophy of brain and cord. Old hemorrhagic softening in left hemisphere. Nodule in left Sylvian fissure. Extensive bilateral cord degeneration.

17. **Pituitary Gland in Epileptics.**—The sellas from a series of unselected epileptic subjects examined by Munson presented a wide variation in type. The average size seems a trifle smaller than the figures given for normals and the contained gland seems to weigh less. Roofing will be seen in the roentgenogram, but in reality the gland is well exposed and pressure seems a remote possibility. Bony changes are present but seem to be the anomalies which might well be present in a similar series of nonepileptic cases. There was no characteristic change to be seen in epileptic sellas.

18. **Intravenous Serum Treatment of Cerebrospinal Meningitis.**—A camp epidemic of 208 cases of cerebrospinal meningitis is reported by Herrick. He claims that the disease is in most, probably in all, instances a primary meningococcus sepsis with usual, but not necessarily universal, secondary meningitis. The diagnosis can be made in at least 50 per cent. of the cases in the premeningitic stage of sepsis. Treatment by large amounts of antimeningococcus serum intravenously, combined with active spinal drainage and intraspinal serum administration, has reduced the duration of the disease, the number and severity of complications and the mortality. The total mortality of the entire series of 203 cases is 26 per cent. In the 129 cases treated by intraspinal methods alone or with intravenous serum doses of 10 to 45 c.c., it is 31.7 per cent.; in 79 treated by larger amounts of serum intravenously and average or smaller amounts intrathecally, 16.4 per cent. The mild cases do well by either method of treatment. It is in the severe types that the intravenous methods give the most striking results. Another important effect of intravenous therapy is the apparent reduction in number of complications.

52. **Enzymes of Tubercle Bacillus.**—As a result of experiments Corper and Sweany state that evidence of the presence of a connective tissue, or elastic tissue, disintegrating enzyme in the tubercle bacillus was not obtained, at least by the methods used for this purpose. Tubercle bacilli of both the human and bovine varieties possess autolytic enzymes, as indicated by the noncoagulable nitrogen and amino-acid, a nitrogen liberated at incubator temperature after the bacilli have been killed by toluene and chloroform. The bacilli themselves, or autolysates therefrom, also possess a trypsin-like enzyme capable of splitting proteins in alkaline solution, an erepsin-like enzyme capable of decomposing peptone in acid solution, a weak pepsin-like enzyme capable of splitting proteins in acid solution, a nuclease capable of splitting nucleic acid and a urease capable of decomposing urea. The tubercle bacilli, or autolysates therefrom, do not possess enzymes capable of hydrolyzing starch or inverting sucrose, demonstrable by the delicate Lewis and Benedict picramic acid method. Autolysates from tubercle bacilli do not possess enzymes capable of digesting elastic tissue prepared from lamb lung, or .connective tissue prepared from tubercles, at least.

58. **Health and the Army Uniform.**—Nowhere, says James, is the irrational in dress more striking than in military life. In private life, excepting for fashion and modern police requirements, every man is at liberty to dress as he wishes. In the army his dress is determined for him without any choice on his part. Military tradition and a desire to look different from other armies seem to have been the determining factors. The chief points in the army uniform that seem not to be in accord with the principles before demonstrated and which prevent free contact between the skin and the air, which is necessary for health, resistance to disease, and for efficiency, are the closefitting woolen and often padded coat which must always be kept closely buttoned; the high closefitting collar; the woolen puttees resembling the bands in which the legs of infants were swaddled in a former and more barbaric age; and the regulation which necessitates the constant wearing of the hat or cap when out of doors. The modern soldier is almost hermetically sealed from the soles of his feet to his chin. From the point of view of modern science the clothing of the navy is far more rational than is that of the army. The open front blouse and the bell-bottom trousers flapping in the wind secure at least a moderate exposure of some part of the body.

7. **Nonunion of War Fractures of Mandible.**—Among 270 cases of jaw fractures which have come under the care of Cole and his associate Bubb immediately or soon after the infliction of their injury, there were thirty ununited fractures, an inclusive nonunion percentage of approximately eleven.

Of these thirty cases, union was in twelve absolutely hopeless; judged by no matter how exacting a standard. The resulting figure is approximately 7 per cent. In the treatment of many of these cases use has been made of a pedicled graft method which Cole regards as being a novel procedure. He used that portion of the jaw lying in front of the masseter attached to its lower margin the deep cervical fascia, to its outer surface the platysma, and to its inner surface near the symphysis the anterior belly of the digastric. On clinical and anatomic grounds this portion can be detached and utilized as a pedicled graft. The feasibility of the procedure was clearly demonstrated at operation. The procedure adopted is as follows: The skin incision is made extending well into the neck reaching a lower level in front than behind A flap consisting of skin only is raised to the requisite level. The posterior fragment is thoroughly exposed. The extremity only of the anterior fragment is exposed, so that the extent of the gap may be gaged. An incision is then made through the soft parts clothing the outer aspect of the anterior fragments at a level immediately below the buccal sulcus. The basal margin of this portion of the jaw is then sawed off. The periosteum on the inner aspect of the fragment is incised. Lateral incisions through platysma and deep fascia are made to define the pedicle, which is then dissected from the underlying structures.

The graft is thus freed to an extent sufficient to allow easy adaptation in its new position. The posterior fragment it now freshened to provide as broad a surface of contact as possible. Anterior and posterior fragments are now drilled for the passage of a fine silver wire. The wires are passed through the pedicle, surround the graft, and, when tightened and twisted, ensure snug contact between graft and freshened fragments. The soft parts are brought together with a few catgut sutures and the skin is sewed up. A drainage tube is inserted and retained for twenty-four hours. The vast majority of ununited fractures occur on the lateral aspect of the mandible and exhibit a gap rarely exceeding 3 cm. in length. This operation, then, enjoys a wide range of applicability. The results obtained by this method are rapid and certain. Cole says that to such an extent is this so that in cases with nonunion, amenable to treatment by means of a pedicled graft, success can practically be guaranteed.

8. **Bone Grafting in Injuries of Mandible.**—The authors report nine cases of jaw injury in which tibial bone grafts were implanted successfully.

11. **Gunshot Injuries of Peripheral Nerves.**—Stopford points out that there is strong reason to conclude that irritative nerve lesions can produce changes in the walls of the arteries supplied by the affected nerves. These changes seriously reduce the caliber of the vessel and must inevitably diminish the blood supply to the muscles, bones, joints and skin. From the clinical and pathologic evidence brought forward in this paper it seems probable that the so-called trophic disturbances are the result of vascular changes produced by an irritative nerve lesion. The contention held by Todd that vascular changes precede trophic lesions is strongly supported by Stopford's clinical observation. The appearance of gangrene and other features in the late stages of some of his patients who had received uncomplicated gunshot injuries of peripheral nerves strongly suggested arterial obstruction, although there was no indication that any main blood vessel had been primarily or secondarily implicated by the injury or healing of the wound. The constant fibrous contracture of muscles in these cases showed a more serious condition than was to be expected from a simple nerve injury, and the histologic examination points to this being due largely to diminished blood supply in consequence of the endarteritis. It is important to emphasize the fact that this contracture is only found to occur in the muscles whose nerve supply has been affected.

13. **Cardiac Pathology.**—The diagnosis of the condition, Price says, rests on the detection of the extremely rapid contractions of the auricle, and this is not infrequently impossible without the employment of the polygraph or electrocardiograph; indeed, in some cases a correct diagnosis cannot be made with certainty, even though the polygraph be employed, an electrocardiographic examination being necessary. Besides it is necessary to distinguish the electrocardiograms of auricular flutter from those of auricular fibrillation. In the case of the latter, however, the R deflections occur at irregularly irregular intervals; the amplitude of the R deflections varies from cycle to cycle; and there is often no relation between the length of a pause and the amplitude of the deflection R which follows it, that is, a short pause may be followed by an R deflection of large amplitude and a long pause by one of small amplitude. In the case of auricular flutter it will be found that these features are not present, even though the ventricular rhythm is markedly irregular. Further, the deflections due to auricular systole in cases of auricular flutter may be distinguished from the oscillations that are found in auricular fibrillation. In the case of the former they are less frequent, ranging between 180 and 380 per minute, rhythmic, and of constant form in each lead, whereas in the latter they are more numerous, irregular in rhythm, inconstant in form in each lead, and smaller in size.

Whenever an individual is conscious of a marked increase in the cardiac rate or complains of attacks of palpitation, occurring suddenly and without apparent cause, or suffers from dyspnea on exertion and other indications of cardiac failure coming on rapidly, the possibility of auricular flutter should be considered, especially if the rhythm of the pulse be regular Auricular flutter should be diagnosed from tachycardia associated with a normal rhythm. When the attacks are transient absolute rest is advisable and the treatment is that of paroxysmal tachycardia. When they are of longer duration, or the condition has become permanently established one of the digitalis series of drugs should be administered in large doses. One may employ the tincture of digitalis, commencing with a dram, or in urgent cases with even 1½ or 2 drams, per diem. These doses should be continued until the full physiologic reaction is obtained. After this one or two plans may be adopted: (1) The dosage may be lessened, and afterward the administration of the smallest dose necessary to control the ventricular rate continued in the hope that the flutter may cease; or (2) large doses may be continued, in the hope of inducing auricular fibrillation, after which the administration of the drug is discontinued for some days in anticipation of a return to the normal rhythm. Price says that the first plan is generally to be preferred.

15. **Inoculation Against Typhoid.**—A brief partial report is made by the authors in order to record their observations made on animals and man in relation to the use of triple vaccine. They were from the first of the opinion that the doses recommended and employed by Castellani were too small, and of this they soon became convinced. In their own investigations they have used vaccine made up to the following strengths per cubic centimeter: (1) 1,000 million *B. typhosus;* 500 million *B. paratyphosus* A; 500 million *B. paratyphosus* B; (2) 1,000 million *B. typhosus;* 750 million *B. paratyphosus* A; 750 million *B. paratyphosus* B; (3) 1,000 million *B. typhosus;* 1,000 million *B. paratyphosus* A; 1,000 million *B. paratyphosus* B. As regards the degree of local and general reaction produced by the inoculations the authors found that the vaccines do not produce appreciably greater disability than the ordinary typhoid vaccine. Comparing earlier results, following the use of the weakest vaccine, with those obtained with the two stronger vaccines the authors have no doubt that both the degree of immunity developed and its duration were distinctly greater in the case of paratyphoid A and B where the stronger vaccines were used. This was particularly evident in the case of paratyphoid A.

Curves of agglutinin formation worked out on man have enabled Dreyer and his associates to reach the following general conclusions: (*a*) as the result of a single first inoculation with triple vaccine. 1. Agglutinins begin to make their appearance in the serum about the seventh day. 2. Thereafter they undergo a rapid increase in amount, reaching their maximum somewhere between the sixteenth and the twenty-fourth day, usually about the eighteenth to the twentieth. 3. After the maximum is passed a regular fall begins similar to that familiar from animal experiment. 4. The actual height of the titer reached for each bacillus varies very greatly with the individual subject of inoculation, as also does the relative height of the titers obtained respectively for T., A, and B. Nevertheless, the individual differences in reaction remain very striking. These facts suggest an explanation of how it happens that one individual freely and continuously exposed to typhoid infection may not become infected (while others similarly situated may do so), but will, nevertheless, readily acquire infection if exposed to paratyphoid A or paratyphoid B as the case may be, and similarly mutatis mutandis. (*b*) What occurs when the usual routine of giving two inoculations at ten days' interval is followed.

At the moment when the second inoculation is given the rise in agglutinin titer following the first inoculation has usually just begun to become rapid. There occurs immediately a marked change in the rate of agglutinin production. This change is normally characterized by an actual fall in the curve of a few days' duration, after which the rapid rise again sets in and reaches its maximum between the sixteenth and twenty-fourth day, most frequently the eighteenth to twentieth day. The regular fall, then, follows as in the case of a single inoculation. It follows that the use of two inoculations, at least, is an essential feature in the prophylaxis of enteric fevers, since it secures a more persistent relatively high immunity. A most important factor affecting duration of immunity is the time interval allowed between the first and second inoculation. A more lasting immunity is obtained by administering the second dose of vaccine at a time when the effect of the first has reached (approximately) its maximum. The authors are of opinion, therefore, that it would prove advantagous to lengthen the interval between the first and second dose of vaccine from ten days to eighteen or twenty days (about three weeks) in making prophylactic inoculations against typhoid and paratyphoid.

18. **The Oil Pustules of Munition Workers.**—Summarized in the Paris Letter, page 1247.

19. **Nervous Form of Slow Endocarditis.**—Claude recalls that malignant endocarditis with a protracted course was described by Jaccoud in 1882. Osler has called attention recently to the frequency of infectious nodules and purpura in its course, and he has also described a meningitic form endo- which belongs, however, more to the acute type of carditis. Claude here reports a case, in a young man, of typical slow endocarditis remarkable in that the symptoms menin- were predominantly nervous: a two months' chorea, gism, hemiplegia and alternate facial paralysis. Necropsy six months after the first symptoms showed foci of infectious arteritis with ectasia. Fine chains of streptococci were found in sections of the mitral valve.

21. **Treatment of Grave Stenosis of the Esophagus.**—Sencert reports two new cases which bring to fourteen the number of his cases of practically impassable cicatricial catheteriza- stenosis of the esophagus corrected by retrograde tion. An opening is made into the stomach and then, ten or esopha- fifteen days later, he works a fine catheter up into the gus from below, under direct visual control through the gastrostomy. This allows a thread to be drawn through the esophagus, and a fine rubber tube, tied to this thread, can be drawn through. A thread tied to the tube is drawn through with it and is left till next day when the progressive dilation is continued.

26 Amputation *to Precede Disarticulation.* P. Bertein.—p. 216.
27 Feet *Frozen in* Repatriating Trains. F. Baup.—p. 220.

22. ***Amputation of the Foot.***—From their comprehensive study of prostheses applied for partial or total amputation of a foot, Trèves and Paramelle declare that the functional use of the leg is more nearly perfect when the amputation removed the whole of the foot. Amputation in the lower third of the leg gives the best results, farmers, mechanics, and others being able to resume their occupation in practically exactly the same conditions as before their injury, after they once get accustomed to their artificial leg. The leg is stouter and is not so liable to get out of order as the more complicated artificial foot. A severely maimed foot is more of a handicap than an artificial leg. In the present state of things, the best advice to give for severe mutilation of the foot is to have it amputated at the ankle. (The concluding portion of this article was suppressed by the censor.)

23. **Dental Infections.**—Baude insists that with enlarged glands in the neck, the primary lesion should be sought in the teeth, before incriminating the tubercle bacilli. If there is not already softening, treatment of the teeth generally brings the return to normal of conditions in the glands. In a large proportion of cases the tubercle bacilli locate only secondarily in the inflamed glands. Ordinary inflammation makes the bed for tuberculosis, in both children and adults. He has encountered cases of chronic septicemia from oral sepsis, and urges that the physician should insist on the teeth being put in order as an indispensable element of whatever treatment he is instituting. If the patient cannot afford the time or expense for careful dentistry, the tooth should be pulled.

24. **Difference Between Internal and External Temperature.**—Satre found in all but fifty-one of 500 persons examined that the temperature in the rectum was from 0.1 to 0.5 centigrade degree higher than the external temperature. The average was 0.3, and this may be regarded as the normal, the standard difference between the two temperatures. When the difference is less than this, or more, abnormal conditions prevail. Judging from his observation and clinical experience, the prognosis is fatal when the difference amounts to 1.5 or 2 degrees C. If the figure is 0.8 or 1 early in the disease and keeps at this figure, the outlook is grave but there is still a chance of recovery. Much difference, in the course of an infectious disease, often indicates acute insufficiency of the myocardium. When he finds that the difference is 1 degree, he begins to give stimulants and stops all cooling baths and packs, to refrain from augmenting further this heart weakness. When the difference keeps within the normal range in the course of acute infectious diseases, the outlook may be regarded as good, notwithstanding the delirium, rapid pulse and occasional arrhythmia. An abnormal difference in the course of convalescence from diphtheria, warns of acute insufficiency of the myocardium. In chronic heart disease, the difference may amount to 1 or 1.2 degrees; as it goes higher than this, the prognosis grows graver. A difference of 1 degree differentiates cardiac asthma from other forms of asthma, and organic tachycardia from the nervous form. A difference within normal excludes appendicitis and peritonitis, suggested otherwise by the symptoms. With all internal or external purulent affections, there is a difference of about 1 degree.

Presse Médicale, Paris

March 14, 1918, **26**, No. 15

28 *Treatment of Deformity of Hand or Foot from Contracture. J. Boisseau *and* M. d'Oelsnitz.—p. 133.
29 *The Rhythm of Retention of Salt. P. Vallery-Radot.—p. 135.
30 *Spinal Anesthesia by Lumbosacral Cocainization. P. Delmas.—p. 137.

28. **War Contracture of Hand or Foot.**—Illustrations are given of hand or foot in extreme contracture cured by a single sitting. The curability is independent of the duration, of the degree of secondary disturbances, and of the clinical form of contracture. Boisseau and d'Oelsnitz report all cured but 9 in 143 cases of contracted hand, *mains figées*, and all cured but 6 in 62 cases of war clubfoot. The mental condition is that of hysteria, and this is responsible for the motor disturbance. The preparation of the patient by a wholesome environment with his mates in the ward, the contagion of example, and the direct or indirect progressive psychotherapy proper of the motor disturbance, are reenforced by weak faradic electricity. In 81 hand cases and 44 foot cases the contracture was overcome at the first trial. They regard it as important from a prophylactic point of view to have these men return when cured to their mates in camp. The outlook for them then is on the same plane as for any men with the hysteria temperament.

29. **Rhythmic Retention of Salt.**—Radot emphasizes that from 10 to 15 per cent. of the chlorids ingested is retained in physiologic conditions. If after a salt-poor period a normal person takes 10 gm. of additional sodium chlorid, part of this is retained for two or three days. The rest is thrown off by steps until the salt balance is reached, and then practically all the salt ingested is eliminated. In chronic nephritis there is more or less accentuation of the normal retention, and of the elimination by steps, *échelons progressifs*. The elimination of salt may increase from less than 2 gm. to over 10 gm. in the third or fourth day in the normal; or not until the seventh day; or it never reaches 5 gm.; or even 1 gm.—these are the three different types of retention of chlorids with diseased kidneys. This test ingestion daily of 11.5 gm. of sodium chlorid, after the patient has been getting only 1.5 gm. for some time, is the only means for determining with precision the permeability of the kidney for chlorids. But it is indispensable to watch the elimination for ten or twelve days in dubious cases, as the elimination may be only retarded. To attempt to draw conclusions in two or three days after giving the superposed 10 gm. is misleading.

30. **Lumbosacral Cocain General Anesthesia.**—Delmas states that in his 300 cases and in Le Filliatre's 3,000, there have been no mishaps with this cocain technic, which he here describes in detail. Two antagonistic injections are given first; one of 1 mg. scopolamin and 1 cg. morphin, the other of 3 mg. of strychnin to counterbalance any toxic action from the other. The eyes are bandaged to ward off dizziness. After waiting half an hour, two more antagonistic injections are made, one, subcutaneous, 5 cg. of spartein. The other is the intraspinal injection of from 2 to 6 cg. cocain, dissolved in the spinal fluid. The analgesia begins in the feet and gradually extends up to the head, going off in inverse order. Delmas reiterates that this method permits anesthetization of any segment of the body desired, including the head, without any disagreeable by-effects at the time or later.

35 *Displacement of Liver from Interposed Intestine. L. Moreau. —p. 92.
36 Posterior Mastoiditis. R. Moreaux.—p. 95.

32. **Symptoms from Complete Section of Spinal Cord.**—Lhermitte warns that the symptoms observed at first may give way to others later. This change is responsible for the conflicting testimony that has been published on this subject. All discrepancies are explained by the varying length of time since the injury to the cord. He analyzes the different symptoms, especially the tardy exaggeration of the reflexes and the automatic defensive movements, spasmodic contraction of certain muscles. Cases of this kind seem to demonstrate that certain centers must exist in the spinal cord which preside over skin, tendon and bone reflexes.

34. **Somnambulism in Hysteria and Epilepsy.**—The practical conclusion of Bernheim's study of this subject is that the somnambulism is merely a secondary manifestation, superposed on the hysteria or the epilepsy. Hence the somnambulism is amenable to psychotherapy.

35. **Ptosis of Liver from Interposed Loop of Intestine.**—In one of Moreau's two cases the colon had become interposed between the diaphragm and the liver; in the other case, loops of small intestine. In the first case a cancer of the stomach was evidently responsible for the displacement, by traction from adhesions. In the other case there was cystic disease of the intestines.

Revue de Médecine, Paris

July-August, 1916, **35**, No. 7-8, Published November, 1917

37 The Menace of Declining Vitality in French Nation. L. Landouzy. —p. 407.
38 *Nervous Shock. H. Roger.—p. 422.
39 War Microbian Skin Diseases. H. Gougerot.—p. 461. Continuation.

42 *Variations in Pressure of Cerebrospinal Fluid. E. Cottin and C. Saloz.—p. 511.
43 Sugar Content of Blood after Inhalation of Chloroform. R. Lepine.—p. 528.

38. **Nervous Shock.**—Roger analyzes nervous shock as a set of inhibiting phenomena following on some violent excitation, and entailing secondary paralysis of the centers primarily excited or inhibited. The dynamic disturbance is felt in all or nearly all the cells of the entire body. It arrests or modifies their functioning, thus inducing a series of new morbid manifestations: reduction of the blood pressure; attenuation of the cellular metabolism; lowering of the temperature; disturbance in the internal and the external secretions; acidification of the blood, and reduction of the proportion of carbon dioxid. Thus, as the process develops, it keeps growing more complex. Physical and chemical manifestations become superposed on the primary dynamic disturbances. Treatment, therefore, must be addressed to all three. Shock retards the action of drugs. He has found that frogs in a state of shock from a blow on the head or an electric shock did not respond to the effect of a poison until after a period eight or ten times longer than under normal conditions, even when strychnin, for example, was injected by the vein. Roger reviews the various measures in vogue for combating shock, including pneumatic pressure to drive the blood from the periphery inward after severe hemorrhage; anesthesia of the region, and inhalation of carbon dioxid with oxygen.

40. **Diagnosis of Pregnancy from the Urine.**—Koopman's trials of various technics for this purpose proved disappointing, with the exception of the miostagmin reaction. For this he uses a stalagmometer, an increase in the number of drops from the capillary tube or the weight of the fluid thus dropped, per second, is the miostagmin reaction. In thirty pregnant women he found that the urine always showed two or three more drops than the controls, up to six drops. The only misleading findings he obtained were in a case of cancer of the esophagus and one of uterine fibroma. The reagent used was an extract of chorionic villi, or Izar's reagent (1 c.c. each of linolic and ricinolic acid), or Abderhalden's placenta antigen.

42. **Pressure in the Cerebrospinal Fluid.**—Cottin and Saloz found wide variations in the pressure in healthy persons according as they were seated, standing or reclining. In eighty pathologic cases the variations were still more marked, but no special laws for this could be detected. In normal persons the pressure was from 20 to 23 cm. water, reclining, and from 40 to 42 cm., seated. Hence in recording the pressure the position at the time should be specified.

44 *Paralysis Left by Anterior Poliomyelitis. H. Hoessly.—p. 305.
45 *Internal Topography of Peripheral Nerves. H. Hoessly.—p. 309.
46 *The Function of the Patella. H. Hoessly.—p. 311.
47 *Lactation and Mammary Cancer. B. von Steiger.—p. 312.
48 "Iron Placenta" Test for Pregnancy. Kottmann.—p. 318. See Abstr. 51, p. 658.

44. **Sequels of Poliomyelitis.**—Hoessly thinks that it is more than a casual coincidence that, at the Zurich orthopedic institute, in fifty-two patients under treatment for bilateral paralysis from poliomyelitis, one foot was in pronation, and the other in supination. The paralysis always involved the antagonists in the two feet.

45. **Internal Topography of Peripheral Nerves.**—Hoessly has found an instructive means for study of the inner topography of nerves to be research on the peripheral nerves in cases of old central paralysis. In four cases of arthrodesis of the knee requiring operative correction, in patients who had long been paralyzed as result of poliomyelitis nearly twenty years before, a segment of the external popliteal nerve was resected and examined to determine the topography of the fiber tracts. He assumes that the motor fibers must have been all destroyed during the long interval. On this assumption, the findings indicated that the motor and sensory fibers do not run in cables but blend in their course, weaving in and out. This "secondary degeneration method" for determining the internal topography of a nerve may give interesting results when applied to trunk nerves.

46. **The Function of the Patella.**—Hoessly presents arguments to show that one of the main functions of the patella is to serve as a leverage point.

47. **Mammary Cancer and Lactation.**—Von Steiger's statistics from the public hospital at Bern confirm the general assumption that the normal physiologic activity of the mammary glands does not predispose to cancer. In 108 women with mammary cancer, less than 25 per cent. had had normal lactation; more than 50 per cent. had never borne children, and the others had nursed only defectively. The average age of those who had never borne children was 55, while the average age of the others was a little over 52.

50 *The 1917 Epidemic of Malaria. G. Cremonese.—p. 153.

49. **Skull Wounds.**—Riccioli analyzes his experience with thirty-three operative cases of war wounds of the skull. The mortality was 38.7 per cent., and in 16.6 per cent. of the fatal cases the dura mater was apparently intact. The operation followed the wound within a few hours.

50. **Malaria in 1917.**—Cremonese remarks that malaria exacted high tribute all over Europe last year, and especially in Italy. Until 1917 malaria in Italy had been gradually assuming a milder form. The ability to procure quinin at cost at every postoffice made it possible for everyone to take it freely, and people did this, even without calling in a physician, aborting the disease as it developed, or materially attenuating it. The only plausible explanation for the virulence of the malaria during 1917 is that new and virulent strains of the malaria parasites had been imported. The quotidian type was especially prevalent. The treatment found successful was a double injection of the quinin (1 gm. bichlorid : two vials), and 2 gm. by the mouth in ten tablets during the day. Then for two or three days, 0.5 gm. by injection and five or six tablets, or ten tablets alone. This was kept up for two or three days; then for about three days, eight tablets; then six for a week (1.20 gm.), and finally four daily for a month (0.80 gm.). In children over 5 he began also with the 1 gm. by injection, but under this age he gave the quinin only by the mouth.

59 Mycosis from Oospora d'Agatae n. sp. G. D'Agata.—p. 86.
60 Experimental Lesions of the Pituitary. A. Chiasserini.—p. 87 Continuation.

51. **Ascending Cultures of Bacteria.**—Gorini called attention in 1903 to the faculty possessed by certain bacteria of climbing to the surface of the tube of agar when only the condensation fluid at the bottom of the tube was inoculated. Bacteria can be classed by this phenomenon as climbing and nonclimbing, and this supplies another element for differentiating them. It is the most convenient and the most certain method for distinguishing the proteus, and obtaining it in pure cultures. The bacteria of the typhoid group and certain races of colon bacteria are of the ascending type.

52. **Bullet Wound of Heart.**—The small bullet was found close to the sternum of the boy of 8 about an hour after the accident. The grave symptoms indicated hemorrhage in the pericardium but not a trace of perforation of the pericardium could be found. Nevertheless the pericardium was opened with a Y incision and the apex of the heart brought out. A jet of blood suddenly spurted nearly 70 cm. high, but was arrested with the left thumb and finger. With the right hand an X suture was taken in the myocardium and the heart was replaced. The interest of the case lies in the injury of the heart with no signs of perforation of the pericardium. The heart seems perfectly normal now.

53. **Abortive Treatment of Gonorrhea.**—The Italian authorities have recently decreed that soldiers with venereal disease are to be treated in their own units. Especially with acute gonorrhea, this imposes a heavy task on the regimental medical officers. Acute gonorrhea is not infrequent, in spite of all the precautions taken. Vecchia reports the subsidence of all symptoms in four days in eight of eleven men given energetic abortive treatment within thirty-six or forty-eight hours. He first anesthetized the urethra with cocain, and then injected a 5 per cent. solution of silver nitrate and a 4 or 5 per cent. solution of silver proteinate. The dose was 10 c.c. of each, and the injections were given three times a day for three days. The fluid was retained for four or five minutes and the urethra passively stretched to flatten out recesses.

61 *Fever Following Infectious Disease. U. Baccarani.—p. 202.
62 Ossification of Ligaments. C. Guarini.—p. 208.

61. **Meta-Infectious Fevers.**—Baccarani refers to the slight fever he has frequently noted a few days after defervescence in some acute infectious diseases. He accepts as febrile any temperature over 36.5 C. in the axilla in the morning and 36.7 at evening. When it is 37 or 38, he seeks for some complication and almost invariably finds it in constipation, in adenoids, or processes in the internal genitals, the gallbladder, periosteum or heart. Instead of enquiring whether the bowels have moved, he asks the typhoid convalescent whether there was a sensation that the bowels had been completely emptied or not. This often reveals latent constipation in spite of the regular morning movement. In an instructive post-typhoid case related, only this tendency to very slight fever gave the clue to an otherwise latent appendicitis, confirmed by operation. A tendency to cholecystitis may likewise be responsible for the slight fever. The urine may disclose signs of pyelitis, or the fluctuations in the pulse and slight modifications in the heart sounds may reveal a mild endocarditis. Since he has made a special study of this "feverette" after typhoid or paratyphoid, he very seldom fails to discover some cause to explain it. The infectious disease may have roused some slumbering process, or it may have directly damaged the organ. In either event, prompt

discovery and appropriate measures may ward off serious danger.

Rivista di Clinica Pediatrica, Florence

March, 1918, **16**, No. 3

65 Pathogenesis of Infantile Atrophy. D. Pacchioni.—p. 113.
64 *Rachitis. A. Gismondi.—p. 128.

64. **Nature and Treatment of Rachitis.**—Gismondi theorizes to explain the favorable action of cod liver oil, phosphorus and calcium in rachitis, and relates clinical experiences confirming their efficacy. He says that fully 80 per cent. of the children under 2 brought to the dispensary in his town in the last three years have had rachitis. He regards it as a disease of the entire organism, not of the bones alone. The blood and soft parts, as well as the bones, lack the normal content of calcium. His experience indicates that any milk allowed at night after the first year of age directly favors the development of rachitis. A little soft mashed vegetables helps to ward it off, even commencing at the seventh or eighth month. The yolks of eggs, under the age of 2, especially before the child is a year old, have seemed to him to do more harm than good. In treatment of rachitis, he prefers to give the cod liver oil in the form of a 50 per cent. emulsion. To each 100 gm. of this emulsion he adds 0.01 gm. phosphorus. A teaspoonful thus represents 0.5 mg. of phosphorus, and he gives one or two a day, immediately before eating. Along with this, calcium acetate is given, in doses of 0.5 gm. daily, fractioned. He says that a much larger proportion of the acetate is retained—up to 20, 30 or even 60 per cent.—than of the phosphate or citrate. This same treatment has a curative action also in spasmophilia. The results of his experience with this combination in the last three years, he says, could not have been more satisfactory. The outcome has always been most excellent both in dispensary and private practice. Restoration to normal proceeds most rapidly under this treatment during the period of repair. It is at this stage that the child begins to move about more, and the soft bones bend under the weight of the body and the traction from the muscles. The above treatment hastens the consolidation of the bone, and thus materially shortens this danger period before actual deformity results.

66 *Epidemic Meningitis and Serotherapy. A. Fabbretti.—p. 121. Commenced in No. 9, p. 99.

66. **Cerebrospinal Meningitis.**—Fabbretti discusses the present status of serotherapy in meningitis and reports his experiences in thirty-two cases at the hospital for infectious diseases at Florence. The serum does not seem able to arrest the disease in the graver toxic cases, but in the others has a decidedly beneficial action, shortening and attenuating the disease and warding off sequels. To avoid danger of anaphylaxis—which is undoubtedly responsible for the untoward by-effects of serotherapy in certain cases—he advises to push the serotherapy vigorously before the anaphylactic state has time to develop, that is, during the first eight or ten days. After this, the serotherapy should be applied only when there are serious relapses with meningococci in the cerebrospinal fluid. When the fluid is under high pressure, it is best to refrain from injecting the serum. He had serum sickness in seven of his cases. In three cases in which the injection was made after an interval of one or two weeks after the last injection, the meningeal phenomena returned more intense than at first, but subsided within twenty-four hours. One patient had collapse, with cessation of respiration for a few seconds, at the fifth injection, the sixteenth day of the treatment. Two patients had convulsions after the third or fourth injection the second week of treatment. One patient with severe kidney disease did not have it aggravated by the serotherapy but it was benefited by the dietetic measures imposed. Only one of his patients developed appreciable sequels; he was left totally blind, with slight spastic paralysis. The total mortality was 41.3 per cent., but a third of the patients were over 40 years old.

68 Eugregarina Parasites of Arthropods. C. F. Pinto.—p. 49.
69 Addison's Disease. C. Fonte.—p. 50.

67. **Sporotrichosis in Brazil.**—De Rezende describes the case of a woman of 43 who had noticed for a month two red patches on the left hand. They rapidly assumed the appearance of extragenital primary syphilitic lesions, and some improvement followed injection of a salvarsan preparation. This improvement proved only transient, discrediting the diagnosis, but the lesions finally healed under two months of a tonic and iodids internally, plus Reclus' ointment. Soon after, de Rezende encountered a case of similar lesions in a boy of 11. They had begun five months before as hard lumps, but soon ulcerated. After failure of other measures, the lesions healed under cotton dipped in a 2 per thousand solution of mercuric chlorid. No medicine was given internally. There was no enlargement of glands or impairment of the general health in either case. The retrospective diagnosis was sporotrichosis, although this had never been known before in his region. Two other cases in a boy and girl of 15 and 10 confirmed this diagnosis, and recovery was soon complete under potassium iodid internally and local application of the 2 per thousand mercuric chlorid. The girl's arm showed nine lumps—a centripetal lymphangitis. These four cases within a year in a small town in Brazil show that sporotrichosis is not so rare as assumed. The 1 or 2 per thousand solution of mercuric chlorid seems to exert an almost specific action on the lesions.

76 Influence of Arthritism and Endocrine Disturbance on Heart Disease. D. F. Huertas y Barrero.—p. 253.

70. **Hyperemia in Therapeutics.**—Coderque relates that Sehrt and Lindember in Germany have been publishing very favorable reports of the favorable influence of passive hyperemia on the healing of war wounds. They say that the pain vanishes as a rule in ten or twelve hours after the constricting band has been applied. Grenade wounds of joints are said to heal rapidly, with retention of joint functioning. They left the constricting band in place for from six to twelve days but did nothing else to the wound except cover it with gauze and a loose bandage, trusting the cleansing of the wound to the profuse secretion from the stasis hyperemia. Sehrt insists that there is no other treatment that ensures so promptly and so certainly the salvation of limbs and joints with conservation of function. In France, active hyperemia has been applied in treatment of wounds in the form of a jet of superheated air. Coderque has had favorable results with hyperemia induced with a suction glass in mastitis and with the constricting band in gonorrheal arthritis. He declares that there is no antiseptic with such a powerful action as that of induced hyperemia, relieving pain, killing bacteria and softening the tissues. With acute processes, the constriction hyperemia can be maintained for twenty or twenty-two hours at a time, but with tuberculous lesions one or two hours is the rule, skipping one day in five, and supplementing this treatment with heliotherapy. He reports a few cases to illustrate the frequent advantage from hyperemia as an adjuvant.

73. **Prostatism Without Enlargement.**—Seres describes ten operative cases to show the different types of prostate mischief which may induce symptoms resembling those from enlargement of the prostate. In some of the cases there was a group of incipient adenomas, with complete retention. These groups encircled the urethra at a point where there was

stenosis, or they encircled the neck of the bladder, or were in the lumen of the prostatic urethra. They were all readily shelled out. In other cases chronic prostatitis or an intravesical bar caused the obstruction.

84 Normal Beef Serum in Treatment of Anthrax. J. Penna, J. B. Cuenca and R. Kraus.—p. 333. Continuation.

77. **Production of Antitoxin.**—Kraus and Sordelli comment on the numerous questions that have to be solved before the production of immune serums will pass from the empiric stage to a solid scientific foundation. They review the various methods in vogue for rapid production of antitoxin and other serums, and then describe the method they have been using of late to hasten and render more certain the production of diphtheria antitoxin. They injected toxin neutralized with antitoxin, giving progressively increasing doses, and using horses over 10 years old, making the injections twice a week or oftener. One horse, 12 years old, received five injections in twelve days, and seven days later the serum gave 400 units. Two others, 13 and 18 years old, receiving six injections in sixteen days, gave 500 and 300 units. Three other horses given thirteen injections gave 300, 800 and 250 units. These results with old horses surpass in the number of units and in the shortness of the time anything previously realized with the old technic, thus saving both time and expense. The toxin was neutralized with antitoxin up to Ehrlich's "Lo" guinea-pig standard. The results obtained harmonize with and even surpass those recently published by McClintock and Ferry. Experiments are now under way to decide whether the age of the horses is an essential factor .

78. **Raynaud's Disease and Paroxysmal Hemoglobinuria of Syphilitic Origin.**—The man of 36 had moist gangrene develop in the Raynaud syndrome. For seven years he had been having occasional hematuria. He denied syphilis but had had several sieges of gonorrhea. The Raynaud's disease and gangrene had been developing for eleven months, commencing with a septic ingrown toenail. He had lost 21 kg. The Wassermann test was negative. He suffered from the cold one day so that his bed had to be artificially heated. In five or ten minutes after having felt so extremely chilly, he voided almost pure blood. The diagnosis was ignored syphilis plus tobacco poisoning, the latter mainly responsible for the permanent vasoconstriction entailing the Raynaud clinical picture. Specific treatment as for syphilis promptly restored clinically normal conditions, confirming the diagnosis, notwithstanding the negative Wassermann findings and the negative blood findings. Both the Raynaud syndrome and the hemoglobinuria were evidently of syphilitic origin.

81. **Spirochetes and Filtrable Viruses.**—Kraus cites various data which seem to establish that certain spirochetes at a certain stage of their development are so minute that they can pass through a Berkefeld filter. Schaudinn was convinced that the germ causing yellow fever was a spirochete of this type. Organs that contain the spirochete of infectious jaundice yield filtrates which induce the infection in guinea-pigs, according to Japanese investigators. Nicolle has also reported that the filtrate of the blood in typhus is very infectious. Futaki's finding of spirochetes in the kidneys in seven cases of typhus adds another link to the chain connecting spirochetes with invisible viruses.

82. **Venereal Granuloma.**—The extensive ulcerating granuloma was of nine years' standing, but it retrogressed completely under twenty intravenous injections of a 1 per cent. solution of tartar emetic. There was no general reaction after the first injection. The doses were from 0.02 to 0.05 gm. in the first series of six injections, and after this from 0.05 to 0.10 gm. The microphotographs show the characteristic cultures. Zerbini reports two other cases cured likewise with tartar emetic.

86 *Cholecystectomy for Gallstones. J. B. Abalos.—p. 1. Conclusion.
87 *Dyspepsia from Perigastritis. R. Araya.—p. 15.
88 Chronic Cervical Glandular Lesions in Inherited Syphilis. A. Luque.—p. 29.
89 Social Medicine as a Special Chair in the Medical Schools. E. Mazzini.—p. 34.

86. **Cholecystectomy.**—Abalos has removed the gallbladder in 100 cases and advises this operation, as medical measures in treatment of gallstone cholecystitis have only a palliative action. By the technic he describes there is no danger of pseudorecurrence of gallstones, as is liable to occur with Kehr's ligation of the cystic duct. When the gallbladder is free he works from below, but when it is adherent he detaches it first, working from above downward. He severs the cystic duct between two clamps. The clamp seizing the central stump of the cystic duct rests on a wick with epinephrin, which drains the bed of the gallbladder. This clamp is left for two or more days. The cystic artery is clamped with the duct when possible; when not, a separate clamp is applied to this artery and left likewise for two or more days. These retention clamps have to be silver plated or gold plated, to ensure their nonrusting. When he has to operate without an assistant, he uses a retractor which has a special device for lifting the liver up out of the way. By this technic no suture materials are left in the wound. Even the bed of the gallbladder is left to heal spontaneously, with no attempt at peritonization. The incision is sutured except the small opening left for the gauze and clamp. With this technic, no foreign body is left in the tissues, while the whole operatior is so simple it takes very little time. Sprengel's transvers incision, severing merely the rectus, gives ample access as the clamp seizing the cystic duct in the depths does no require much of an opening for it. With this clamp close t the gallbladder, the latter is easily drawn up, exposing th liver. The other clamp, to be left for two days, can b applied with precision and ease to the cystic duct, close t its junction with the hepatic duct. If drainage is indispensable, he drains the common bile duct with a small rubbe tube, but refrains here also from using any suture material He says that cholecystectomy is indicated with rebellion and repeated gallstone disturbances even although there ma not be any stones in the gallbladder itself.

87. **Dyspepsia from Perigastritis.**—Araya reports four case in which long years of suffering from the stomach, dyspepsi and gastralgia, rebellious to all other measures, were cure at one stroke by a laparotomy to break up adhesions fron perigastritis. In one case gastro-enterostomy was don besides. His cases teach anew the lesson of the multiplicit of the causes that may be responsible for stomach distur bances, and the necessity for removing the cause instead o combating symptoms. Pain is the most constant sympton with adhesions; it may range from a simple oppression i the stomach region to actual crises. The pain is generall exaggerated by eating, by movements affecting the abdomen and by walking. It is relieved more or less by reclining o wearing an abdominal band. Pain on pressure below th left false ribs is considered significant by some. The increas in the pain when the stomach is inflated is also instructive it may also show a depression in its outline from traction b some linear adhesion. The symptoms from the dyspepsi from adhesions hampering the stomach may be associate with or masked by intestinal lesions, including appendicitis His patients were all women between 33 and 50, and th adhesions were located at different points.

THE CHICAGO SESSION

AMERICAN MEDICAL ASSOCIATION, SIXTY-NINTH ANNUAL SESSION, CHICAGO, JUNE 10-14, 1918

OFFICIAL CALL

TO THE OFFICERS, FELLOWS AND MEMBERS OF THE AMERICAN MEDICAL ASSOCIATION

The sixty-ninth annual session of the American Medical Association will be held in Chicago, June 10-14, 1918.

The House of Delegates will convene at 10 a. m., Monday, June 10. In the House the representation of the various constituent associations for 1918 is as follows:

Alabama	3	New Hampshire	1
Arizona	1	New Jersey	3
Arkansas	2	New Mexico	1
California	4	New York	11
Colorado	2	North Carolina	2
Connecticut	2	North Dakota	1
Delaware	1	Ohio	5
District of Columbia	1	Oklahoma	2
Florida	1	Oregon	1
Georgia	3	Pennsylvania	9
Idaho	1	Rhode Island	1
Illinois	9	South Carolina	1
Indiana	4	South Dakota	1
Iowa	3	Tennessee	2

The fifteen scientific sections of the American Medical Association, the Medical Department of the Army, the Medical Corps of the Navy and the Public Health Service are entitled to one delegate each.

The general meeting, which constitutes the opening exercises of the Scientific Assembly of the Association, will be held at 8:30 p. m., Tuesday, June 11. The various sections of the Scientific Assembly will meet Wednesday, June 12, at 9 a. m., and subsequently, according to their respective programs.

The Registration Department will be open from 8:30 a. m. until 5:30 p. m., on Monday, Tuesday, Wednesday and Thursday, June 10, 11, 12 and 13, and from 8:30 a. m. to 12 noon, on Friday, June 14.

CHARLES H. MAYO, President.
HUBERT WORK, Chairman, House of Delegates.
ALEXANDER R. CRAIG, Secretary.

MEMBERS OF THE HOUSE OF DELEGATES

A Preliminary Roster of the Legislative Body of the American Medical Association

The list of members of the House of Delegates for the session is incomplete, as a number of the state societies are yet to hold their meetings at which delegates will be elected. The following is a list of the holdover delegates and of the newly elected members who have reported to THE JOURNAL in time to be included:

STATE DELEGATES

ALABAMA
E. F. Moody, Dothan
S. W. Welch, Montgomery.

ARKANSAS
W. T. Wooton, Hot Springs.

CALIFORNIA
A. B. Spalding, San Francisco.
H. P. Newman, San Diego.

COLORADO
L. H. McKinnie, Colorado Springs.
Oliver Lyons, Denver.

CONNECTICUT
D. Chester Brown, Danbury.

DELAWARE
Willard Springer, Wilmington.

DISTRICT OF COLUMBIA
G. Wythe Cook, Washington.

GEORGIA
M. A. Clark, Macon.

IDAHO
C. R. Scott, Twin Falls.

ILLINOIS
Don Deal, Springfield.
R. R. Ferguson, Chicago.
C. J. Whalen, Chicago.

INDIANA
C. H. Good, Huntington.
Miles F. Porter, Fort Wayne.
Charles Stoltz, South Bend
A. E. Bulson, Jr., Fort Wayne.

IOWA
William B. Small, Waterloo.

ISTHMIAN CANAL ZONE
William B. Pierce, Ancon, C. Z.

KANSAS
James W. May, Kansas City.

KENTUCKY
A. T. McCormack, Bowling Green.
M. E. Alderson, Russellville.

LOUISIANA
W. H. Seemann, New Orleans.

MARYLAND
A. McGlannan, Baltimore
Randolph Winslow, Baltimore.

MASSACHUSETTS
F. B. Lund, Boston.
J. B. Blake, Boston.
H. G. Stetson, Greenfield.
L. F. Woodward, Worcester.

MICHIGAN
Guy L. Connor, Detroit.
J. D. Brook, Grandville.

MINNESOTA
H. P. Ritchie, St. Paul.
George D. Head, Minneapolis.

MISSISSIPPI
T. M. Dye, Clarksdale.

MISSOURI
E. J. Goodwin, St. Louis.
R. M. Funkhouser, St. Louis.

MONTANA
Rudolph Horsky, Helena.

NEBRASKA
LeRoy Crummer, Omaha.

NEVADA
William Z. Dahl, Reno.

NEW JERSEY
William S. Lalor, Trenton.

NEW MEXICO
H. A. Miller, Clovis.

NEW YORK
F. M. Crandall, New York.
John O. Polak, Brooklyn.
William F. Campbell, Brooklyn.
Grover W. Wende, Buffalo.
W. Stanton Gleason, Newburgh.
E. Eliot Harris, New York.

NORTH CAROLINA
H. A. Royster, Raleigh.
C. P. Ambler, Asheville.

NORTH DAKOTA
Chas. MacLachlan, New Rockford

OHIO
J. H. J. Upham, Columbus.
H. C. Haning, Dayton.
A. B. Walker, Canton.
B. R. McClellan, Xenia.
C. D. Selby, Toledo.

OKLAHOMA
Charles R. Hume, Anadarko.

PENNSYLVANIA
David N. Dennis, Erie.
Edward D. Heckel, Pittsburgh.
John D. McLean, Philadelphia.
C. L. Stevens, Athens.
W. F. Bacon, York.
George R. S. Corson, Pottsville.
H. B. Gibby, Wilkes-Barre.
George G. Harman, Huntington.
Wilmer Krusen, Philadelphia.

PORTO RICO
Jose S. Belaval, San Juan.

SOUTH CAROLINA
E. A. Hines, Seneca.

SOUTH DAKOTA
Percy D. Peabody, Webster.

TENNESSEE
A. F. Richards, Sparta.
E. T. Newell, Chattanooga.

TEXAS
C. E. Cantrell, Greenville.
H. D. Barnes, Childress.
M. M. Carrick, Dallas.

UTAH
Sol G. Kahn, Salt Lake City.

VIRGINIA
Robert C. Bryan, Richmond.

WASHINGTON
D. E. McGillivray Port Angeles.
H. H. McCarthy, Spokane.

WEST VIRGINIA
C. R. Ogden, Clarksburg.
Frank LeMoyne Hupp, Wheeling.

WISCONSIN
Rock Sleyster, Waupun.
H. M. Brown, Milwaukee.
C. H. Lemon, Milwaukee.

WYOMING
J. D. Lewellen, Powell.

DELEGATES FROM THE SECTIONS

PRACTICE OF MEDICINE
W. J. Stone, Toledo.

SURGERY, GENERAL AND ABDOMINAL
Floyd W. McRae, Atlanta, Ga.

OBSTETRICS, GYNECOLOGY AND ABDOMINAL SURGERY
Horace G. Wetherill, Denver.

OPHTHALMOLOGY
Thomas B. Hollaway, Philadelphia.

LARYNGOLOGY, OTOLOGY AND RHINOLOGY
George L. Richards, Fall River.

DISEASES OF CHILDREN
T. C. McCleave, Oakland, Calif.

PHARMACOLOGY AND THERAPEUTICS
Torald Sollmann, Cleveland.

STOMATOLOGY
William C. Fisher, New York.

NERVOUS AND MENTAL DISEASES
G. A. Moleen, Denver.

DERMATOLOGY
Sigmund Pollitzer, New York.

PREVENTIVE MEDICINE AND PUBLIC HEALTH
Otto P. Geier, Cincinnati.

GENITO-URINARY DISEASES
E. O. Smith, Cincinnati.

ORTHOPEDIC SURGERY
John Ridlon, Chicago.

GASTRO-ENTEROLOGY AND PROCTOLOGY
J. C. Johnson, Hamilton, Ala.

MEDICAL CHICAGO

The Medical Features of the Convention City

The word "Chicago" is derived from an Indian word meaning "wild onion" which should not, however, reflect unfavorably on the metropolis of today. There remains much that is "wild," and from time to time the odor of the stockyards may be reminiscent of the "onion"; but the development of Chicago in literature, in art, in finance, in manufacturing, and as a medical center is typical only of the strength of the onion and of none of its disagreeable features. Its strength is also typified by its ability to continue this life after two very notable relapses—the Fort Dearborn Massacre of 1812 and the Chicago Fire of 1871. Chicago is the fifth largest city in the world, being preceded by London, New York, Paris and Berlin. As there is grave doubt concerning the population of the center of Kultur, Berlin might well be omitted. Forty railroads, twenty-three of which are trunk lines, terminate in Chicago. The development of Chicago as a manufacturing center is measured in figures running into billions, as shown by the annual bank clearings, which exceed twenty billion dollars. However, the growth of the city in literature, art and science has kept pace with its magnificent commercial development.

MEDICAL COLLEGES

It was the custom, not so long ago, for Chicago to boast of the number of medical students it turned out annually; today it prefers to boast of the quality. There are now seven medical colleges in Chicago, three of them listed by the Council on Medical Education of the American Medical Association in Class A, two in Class B and two in Class C.

Rush Medical College: This institution, one of the oldest of the Northwest, was founded by Daniel Brainard in 1837, the same year in which the city was incorporated. At the meeting of the American Medical Association in St. Louis in 1854, Dr. Brainard received a premium from the committee on prize essays for "An Essay on a New Method of Treating Ununited Fractures and Certain Deformities of the Osseous System," which was exceptional for that time. The first two years of the medical work of Rush Medical College have been given at the University of Chicago since the affiliation of the college with the university; the last two years are conducted in three buildings at the corner of Harrison and Wood streets, as well as in hospitals affiliated with the college. The juniors and seniors have thus been strangers to the underclassmen. By raising $3,461,000, the University of Chicago secured a fund of $2,000,000, offered by the General Education Board of the Rockefeller Foundation for the organization of medical instruction at the university. Rush Medical College will therefore merge with the new school and become the Medical Department of the University of Chicago. The plans of reorganization include the erection of a hospital on the grounds of the university on the South side, the transfer of all undergraduate medical education to the university, and the creation of a postgraduate medical school at the present location of the college. By this means the underclassmen will regain the enlightening influence lent by the presence of the higher grades.

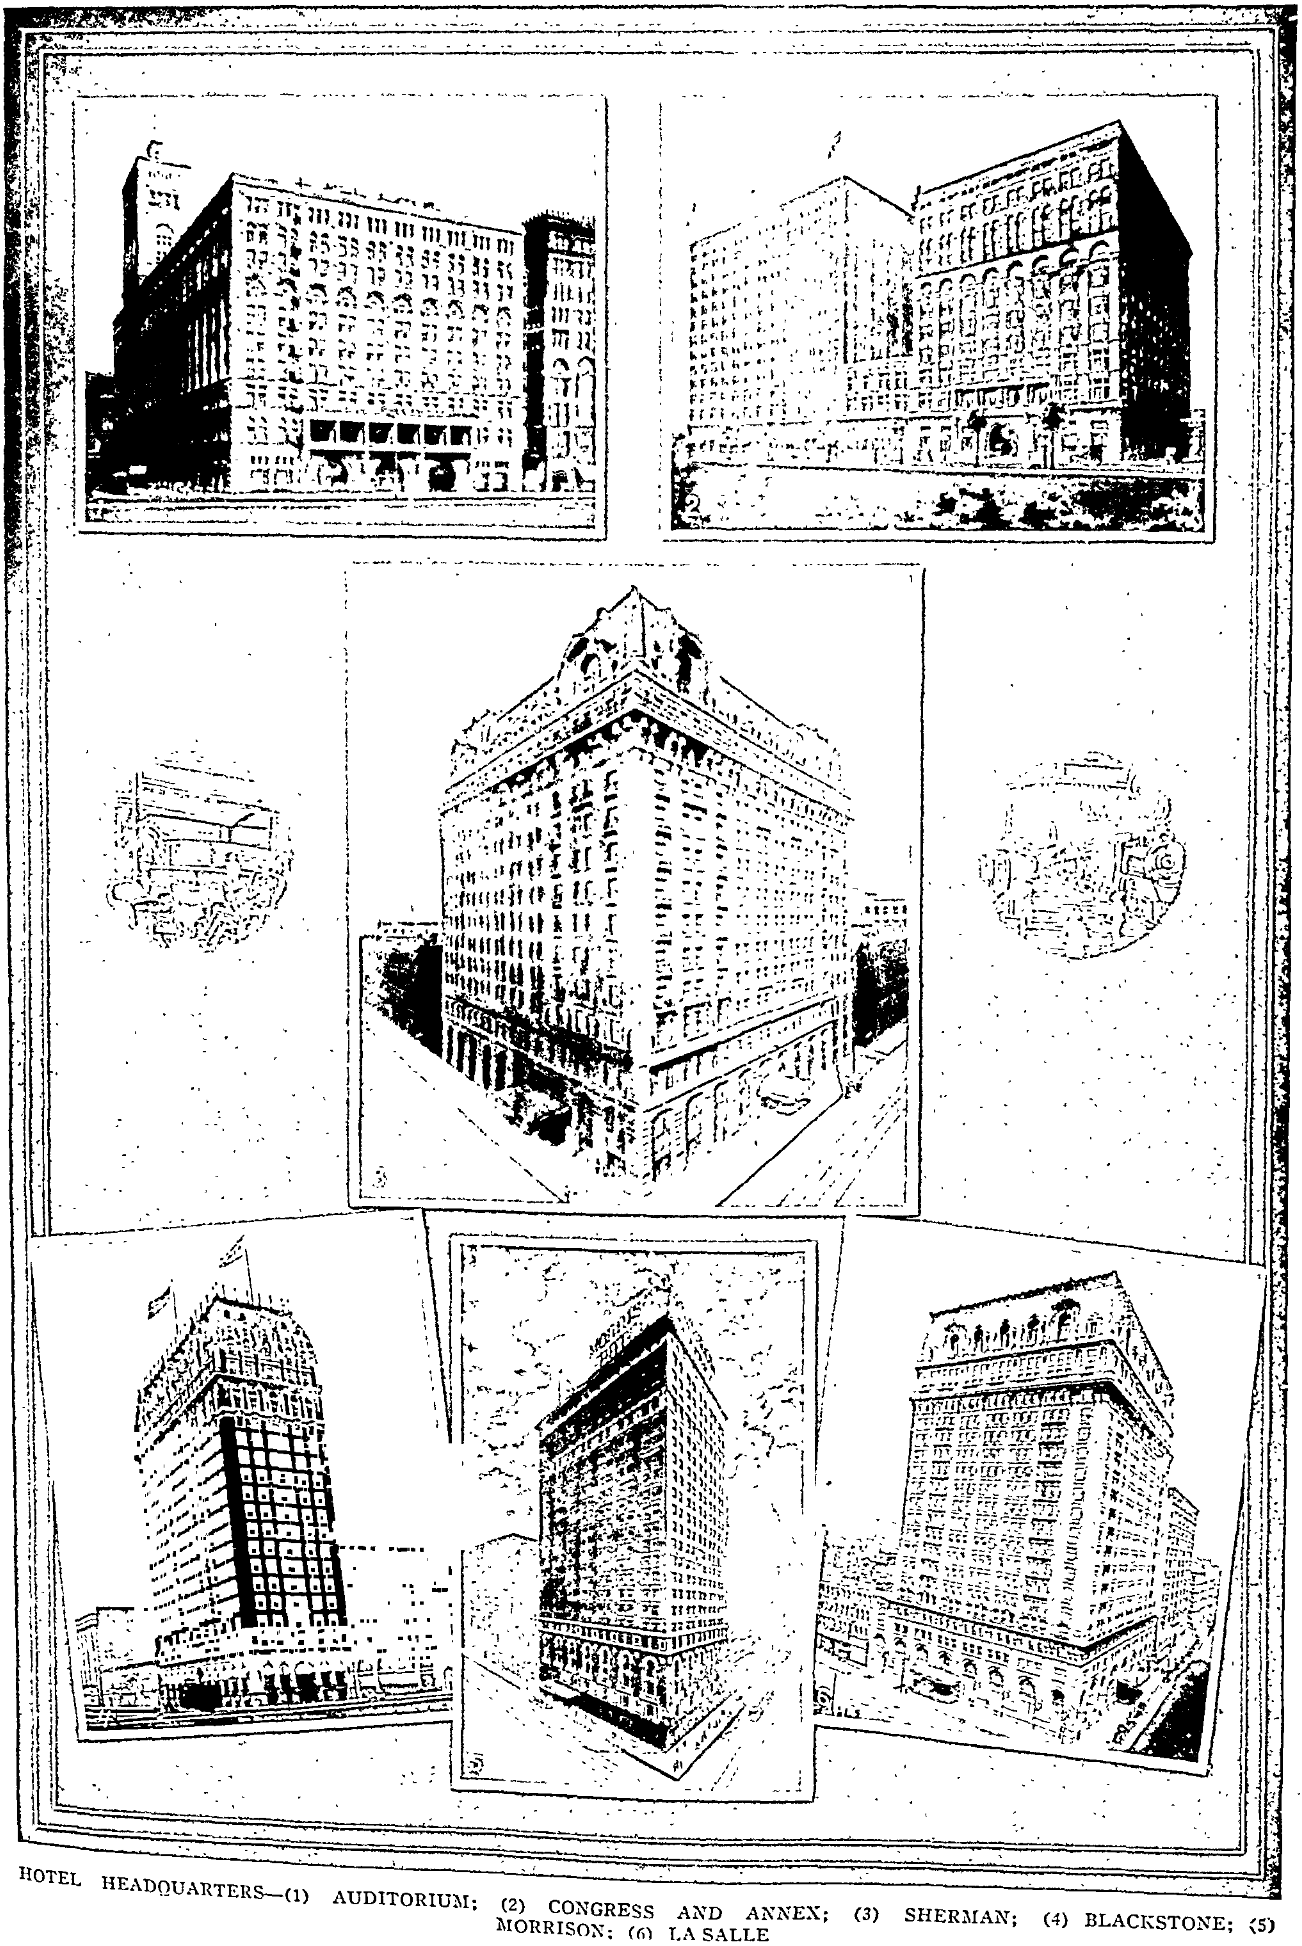
Northwestern University Medical School: This school was established in 1859 by Dr. Hosmer A. Johnson as the medical department of Lind University. In 1864, the Northwestern University Medical School became independent as the Chicago Medical College under the leadership of Dr. Nathan S. Davis, the "Father of the American Medical Association." In 1869, the Chicago Medical College united with Northwestern University, retaining, however, the name of Chicago Medical College until 1891. Adjoining the college building is Wesley Memorial Hospital. Recently Mr. James Deering set aside an endowment fund of $1,000,000 to be used in the maintenance of Wesley Memorial Hospital and in the furtherance of clinical teaching in the medical school. Northwestern University Medical School claims the honor of being "the first American school to enforce a standard of preliminary education, to adopt longer annual courses of instruction, and to initiate, in 1859, the graded curriculum in which studies were assigned in logical order and in which laboratory departments prepared the way for the practical clinical branches."

University of Illinois College of Medicine: This school was organized in 1882 as the College of Surgeons. It became the medical department of the University of Illinois by affiliation in 1897, and an integral part in 1910. In the same year the American Medical Missionary College was absorbed. The relationship with the university was canceled in June, 1912, and was restored in March, 1913. This school is now supported in part by an annual appropriation made by the state, is rejuvenated, and is rapidly growing.

Other Colleges: Chicago is also the home of the Hahnemann Medical College and Hospital of Chicago, of the combined school representing the Chicago College of Medicine and Surgery and the Loyola University School of Medicine (formerly Bennett Medical College), and of the Jenner Medical College and the Chicago Hospital College of Medicine.

POSTGRADUATE MEDICAL EDUCATION

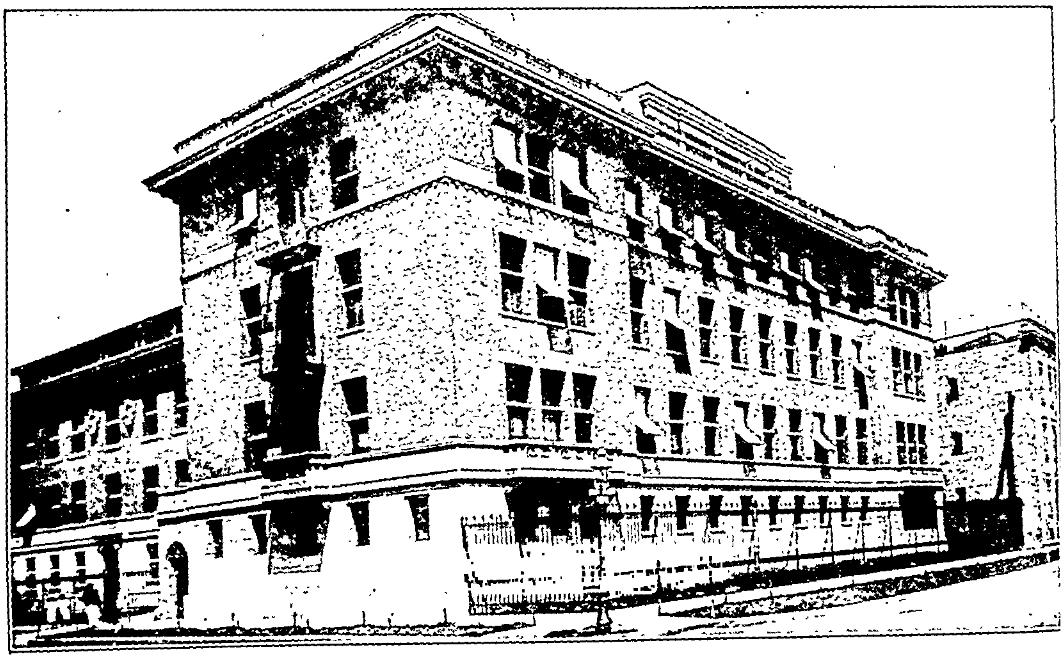
Chicago Postgraduate Medical School: The Chicago Postgraduate Medical School was established in 1887 by a



HOTEL HEADQUARTERS—(1) AUDITORIUM; (2) CONGRESS AND ANNEX; (3) SHERMAN; (4) BLACKSTONE; (5) MORRISON; (6) LA SALLE group of physicians, prominent among whom was the late Dr. John H. Hollister. In addition to the college, a general hospital of 100 beds is conducted by the teaching staff.

Chicago Polyclinic: In 1886, Dr. Truman W. Miller founded this school. Its clinical facilities are furnished by a large dispensary that has been built up in a densely populated portion of the city, and by two hospitals owned by the school—the Chicago Polyclinic Hospital and the Henrotin Memorial Hospital.

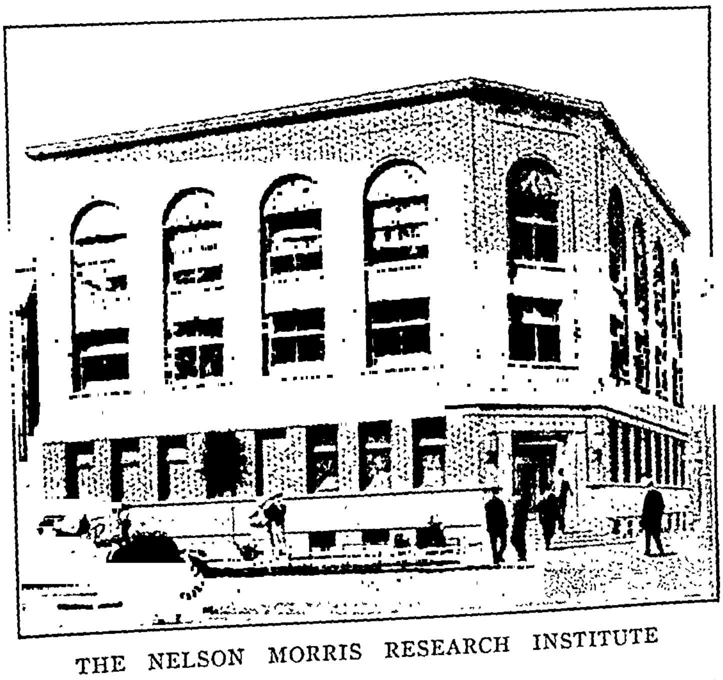
The Illinois Postgraduate Medical School: This school occupies its own building, and in connection with its educational work, it conducts the West Side Hospital, which has an equipment of 175 beds. It is fortunately located in what is known as the medical Rialto of Chicago, of which more will follow.



THE MEMORIAL INSTITUTE FOR INFECTIOUS DISEASES

RESEARCH INSTITUTIONS

Memorial Institute for Infectious Diseases: This institute was founded, Jan. 2, 1902, by Harold F. and Edith Rockefeller McCormick in memory of their son. The first board of trustees consisted of Frank Billings, Christian Fenger, Ludvig Hektoen, Charles L. Hutchinson and Stanley McCormick. It began work at once, utilizing the first floor of the laboratory building of Rush Medical College. In March, 1911, through a bequest from Mrs. Annie W. Durand, the institute was enabled to build a hospital to cost $200,000 with a minimum of forty beds for the free care of persons suffering from infectious diseases. The hospital was formally opened in February, 1913, and in 1914 a laboratory was built at a cost of $100,000. At the present time the total resources of the institute amount to nearly $2,000,000. The institute also has a serum division and publishes the *Journal of Infectious Diseases*. Many important investigations have been conducted by the workers in the institute. Its director is Dr. Ludvig Hektoen.

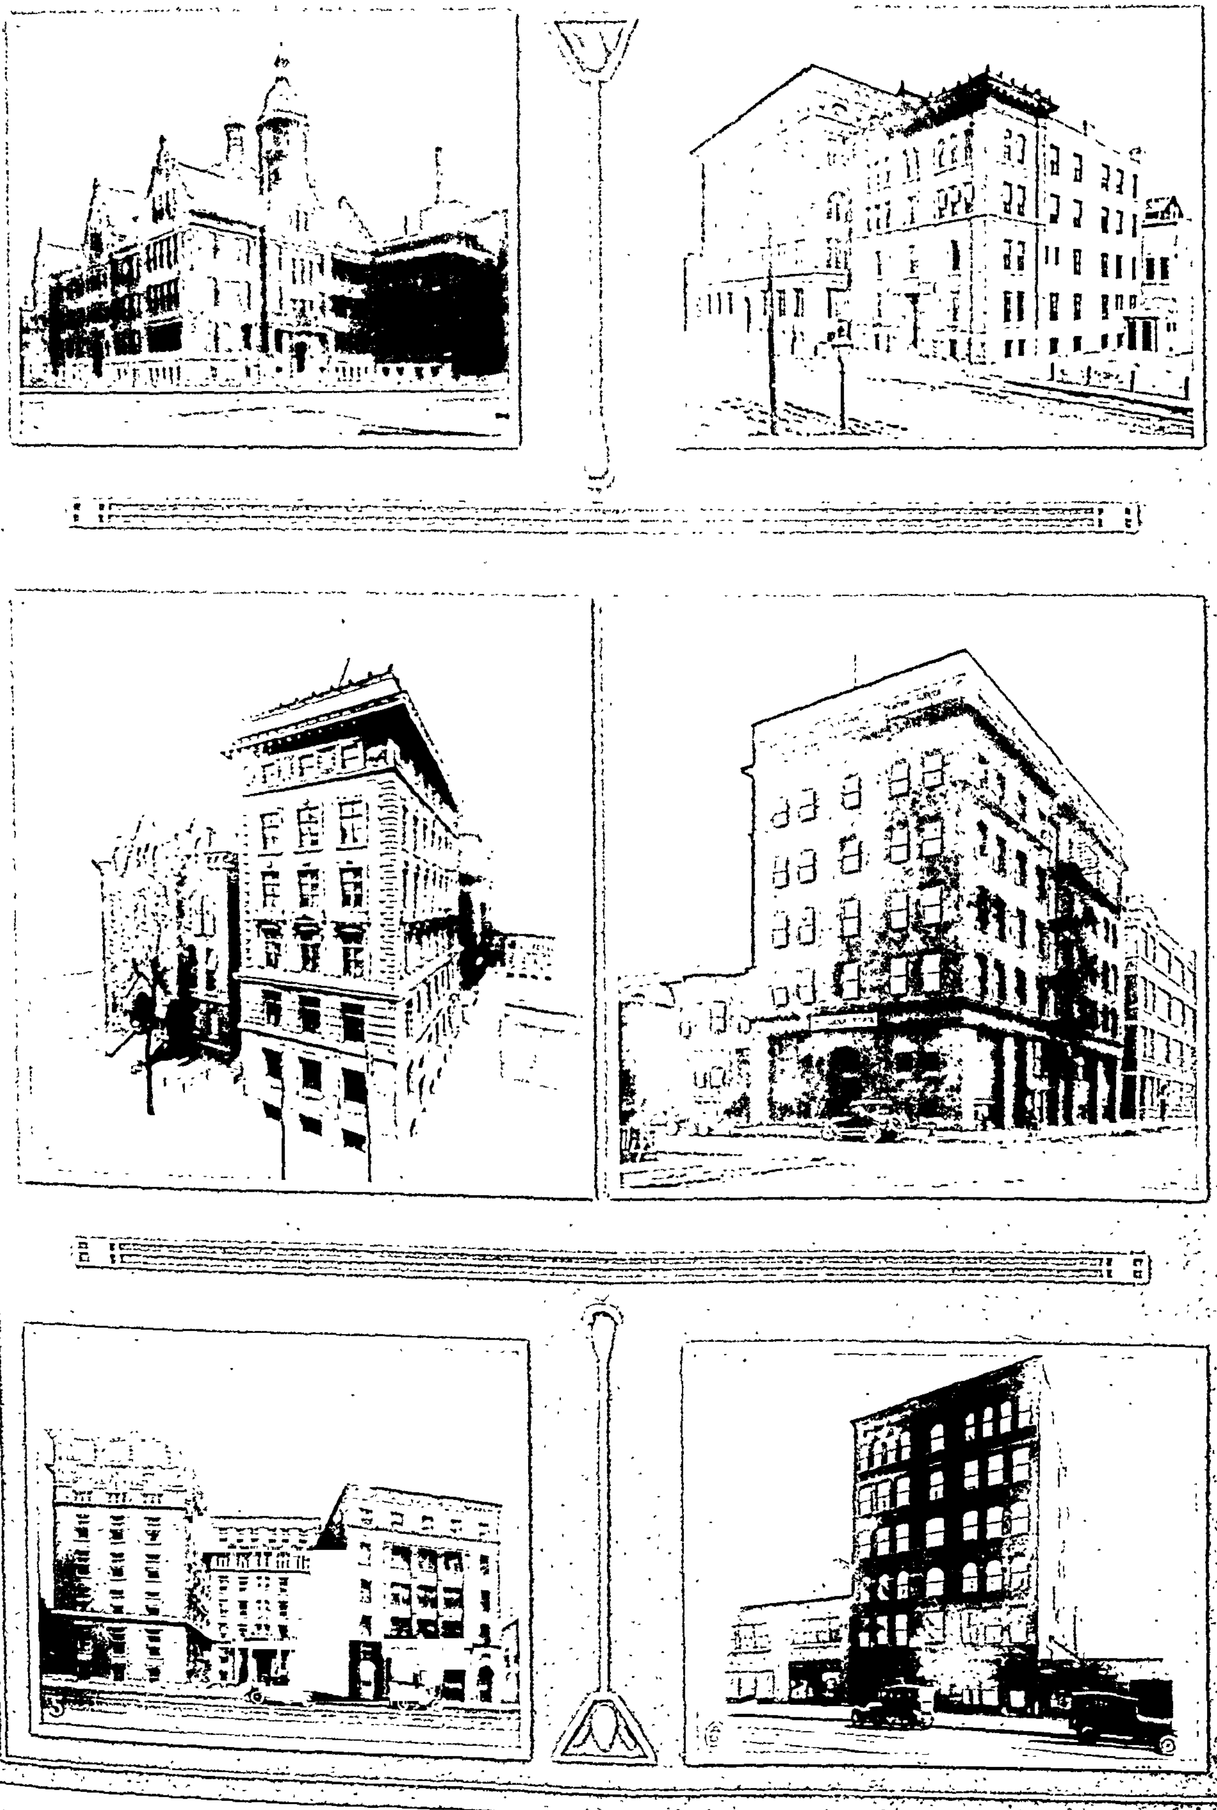


THE NELSON MORRIS RESEARCH INSTITUTE

The Nelson Morris Institute for Medical Research: This institute was established in 1910 as the result of a donation of $500,000 given by Mrs. Sarah Morris to the Michael Reese Hospital in memory of her husband, Nelson Morris, founder of the firm of Nelson Morris & Co. Dr. John A. Hornsby was superintendent of the hospital at this time, and Drs. James F. Jobling and Solomon Strouse were, respectively, pathologist and assistant pathologist. Of the original donation, $375,000 was expended for construction and the balance for equipment. The institution is supported by funds provided by the board of directors of the Michael Reese Hospital. During the present fiscal year the budget of the institute has been $18,000, exclusive of the maintenance of the library, of building maintenance and repairs, and of such general supplies as are obtainable directly from the Michael Reese and Sarah Morris hospitals, all three institutions being under the control of a single board of directors. The institute conducts medical research by its full-time staff and clinical research by those members of the hospital staff to whom research privileges are assigned. In addition, the staff has charge of the routine laboratory work of the Michael Reese and Sarah Morris hospitals. Th institute departmental heads at the present time are: Osca T. Schultz (M.D., Johns Hopkins, 1903), director; Katherin M. Howell (M.D., Rush Medical College, 1913), serology and Withrow Morse (Ph.D., Columbia University, 1909) chemistry.

The Otho S. A. Sprague Memorial Institute: This insti tute was organized in January, 1911, by Mr. Albert A Sprague, brother of the donor, who bequeathed a sum o money for the purpose of relieving human suffering. May 1 1911, Dr. H. Gideon Wells of the University of Chicago was appointed director of medical research. It was decided to use none of the money for the erection of buildings, but to cooperate with existing institutions in furthering medica research. Since its foundation, the institute has supported research work in the University of Chicago, Rush Medica College, the Presbyterian Hospital, the Children's Memoria Hospital and the pathologic laboratories of St. Luke's Hospital and of Cook County Hospital. The staff of the institute consists of about twenty members, exclusive of special assistants and investigators and untrained helpers. Of the investigators, about one half give their entire time to the work of the institute. It has also supported special investigations in industrial diseases, caisson disease, anesthesia, infant health, etc., by special workers. The scientific work of the institute is under the supervision of an advisory council consisting of Drs. James B. Herrick, Frank Billings, Ludvig Hektoen, Joseph L. Miller, E. R. LeCount, and Professors Julius Stieglitz and E. O. Jordan.

The University of Chicago: The University of Chicago was founded in 1857, and after some vicissitudes, in 1886 succeeded in interesting Mr. John D. Rockefeller, who has contributed an amount in excess of $34,000,000 to establish



(1) UNIVERSITY OF ILLINOIS MEDICAL SCHOOL; (2) NORTHWESTERN UNIVERSITY MEDICAL SCHOOL; (3) RUSH MEDICAL COLLEGE; (4) POST-GRADUATE MEDICAL SCHOOL OF CHICAGO; (5) ILLINOIS POST-GRADUATE MEDICAL SCHOOL; (6) THE CHICAGO POLYCLINIC

MICHIGAN BOULEVARD; ON THE RIGHT IS THE ART INSTITUTE

the institution on a firm and lasting basis. The college grounds comprise 92 acres, and there are fifty-three buildings devoted to educational purposes. The buildings are of a uniform type, a scheme of modern Gothic architecture being carried out in all of the structures.

Northwestern University: Northwestern University was founded in 1851, and is located in Evanston, 12 miles north of Chicago. It covers an area of 75 acres. The professional schools are all located in the city of Chicago, including the dental, pharmacy and law schools.

HOSPITALS

There are about eighty-five hospitals in Chicago, most of which are under denominational control. Many of them are closely affiliated with the medical schools, and are under the medical supervision of members of the faculties of the colleges.

Cook County Hospital: The Cook County Hospital occupies 12 acres at Wood, Harrison and Lincoln streets. New buildings recently erected, at a cost of $3,650,000, make this the largest and most modern institution of its kind in the Middle West. There are 2,700 beds available. During 1917, 34,400 patients were treated in the hospital, and 18,612 in the dispensary. An average of eight major surgical operations are performed at the hospital every day, and during 1917 over 10,000 roentgen-ray examinations were made and over 500 necropsies performed. There are two amphitheaters in the hospital, each seating 250 persons, for the holding of clinics.

A part of this hospital is the new psychopathic hospital, erected in 1915 at a cost of approximately $500,000. During 1917, over 4,000 patients were admitted to this department.

The Illinois Charitable Eye and Ear Hospital: This institution was founded by Dr. E. L. Holmes in 1859. It is located at Adams and Peoria streets, and has a capacity of 1,756, with an outpatient service which treats 25,000 patients annually. It is supported by an annual appropriation of about $80,000 by the state, and a recent appropriation of $500,000 provides for a new building. Clinics are held daily, and are open to all physicians who desire to come.

Municipal Tuberculosis Sanitarium: This institution, a part of which is shown in the illustration, is situated at North Crawford and Bryn Mawr avenues, within the city limits, and covers an area of 160 acres. The thirty-two principal buildings, including the administrative headquarters, and a concrete contagious building for men and women, cost approximately $2,500,000. There are 870 beds in addition to eight dispensaries, which are conducted in different parts of the city from which patients requiring institutional supervision are sent to the sanatorium. The sanatorium is supported by the annual taxes levied by the city.

THE CHICAGO MEDICAL SOCIETY

The Chicago Medical Society was organized in April of the year 1850, and continued under this name for two years, when it was changed to the Cook County Medical Society. The society continued until 1858, when it was changed back to its original name, the Chicago Medical Society, which name it has had ever since.

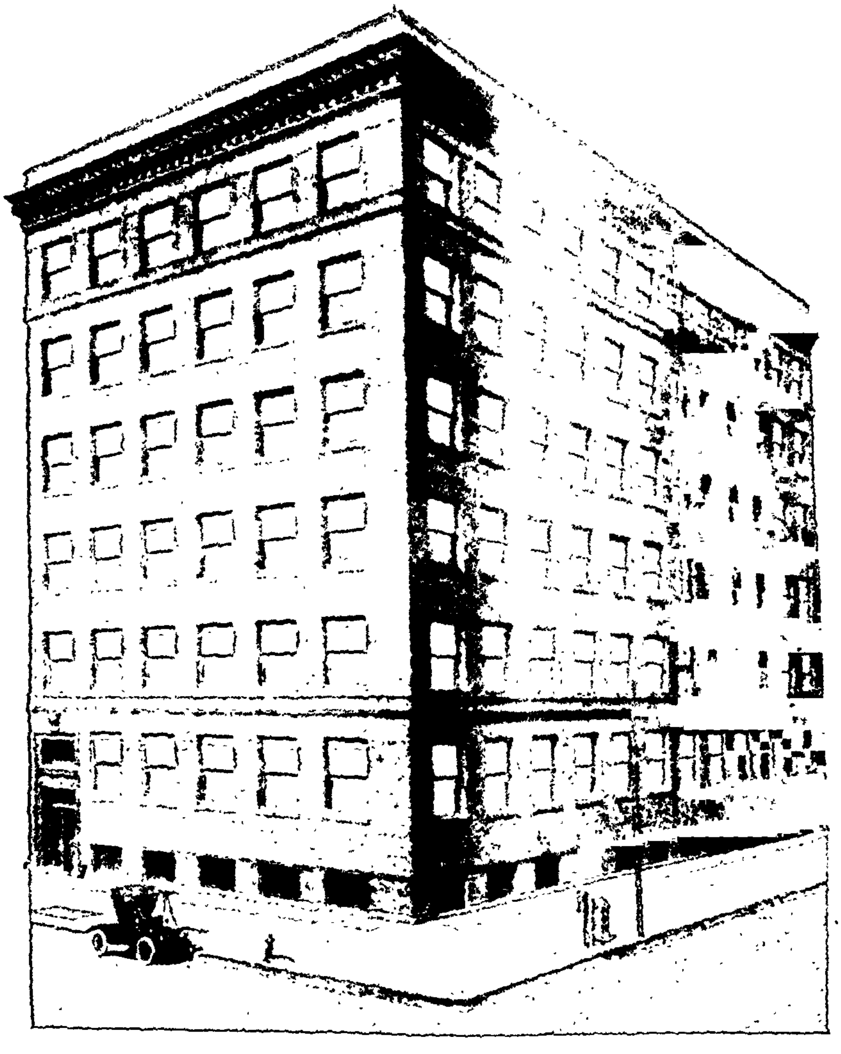
Among the founders of the society in 1850 were Drs. Levi D. Boone, Daniel Brainard, B. McVickar, W. B. Herrick, John Evans, Edwin Meek, J. H. Bird, J. V. Z. Blaney, Samuel W. Ritchey, Phillip Maxwell and N. S. Davis. Dr. Levi D. Boone was elected as the first president.

The society continued under its original constitution as drawn up at that time until February, 1903, when a new constitution was formulated and the society was divided up into districts, or "branches." At that time there were eleven branches with a total membership of 1,315. At present there are fifteen branches, and the active membership of the society is 3,084, a nonresident membership of thirty-five, making a total of 3,119.

The branches have their own branch officers, and hold scientific meetings each month, excepting during the months of July, August and September.

The central society holds a scientific meeting each week except during July, August and September. These meetings are arranged by the secretary and the president, and are presided over by the president.

A weekly bulletin known as the *Official Bulletin of the Chicago Medical Society* is published each week. The *Bulletin* contains the announcements of the central society and of the branches as well as those of the affiliated societies, and each week an abstract is published of the scientific meeting, of the papers read, and the discussions.



HOME OF THE AMERICAN MEDICAL ASSOCIATION

The council of the Chicago Medical Society meets each month, with the exception of July, August and September. The council is composed of fifty-four councilors who are elected by the branches, that is, each branch is entitled to one councilor for the first fifty members and an additional one for the first hundred and one for each additional hundred members. In addition to the councilors elected by the branches, there are five councilors-at-large elected each year to serve a term of three years, and the retiring president becomes a councilor to serve a term of three years. This body is presided over by the president-elect.

The council at its meeting in October elects nine standing committees as follows:

Membership Committee: This committee is made up of three members whose duty it is to investigate the personal and professional standing of all applicants for membership and report on them to the council with their recommendation.

Medicolegal Committee: This committee is made up of three members whose duty it is to represent the Chicago Medical Society on the Medicolegal Committee of the Illinois State Medical Society. They defend the members when sued for alleged malpractice. This legal defense is accorded to every member in good standing, and the expenses are covered by the regular dues, no assessment being made.

The Milk Commission: This is composed of six members and the president ex-officio. The work of the Milk Commission is to secure a supply of pure and clean raw milk that can be relied on for the feeding of infants, and the commission certifies to milk from farms where the milk is produced in accordance with the conditions imposed and equals the standard that has been designated. In addition to this the object is to disseminate knowledge concerning the hygienic importance of a wholesome milk supply.

Ethical Relations Committee: This committee is made up of three members whose duty it is to take cognizance of and investigate and make recommendations on questions affecting the ethical relations of members to each other, to the society, to the profession and to the public. The committee also makes proper investigations of any charges of unethical conduct preferred against any member, and submits its conclusions and recommendations to the council.

Criminal Abortion Committee: This committee is made up of three members whose duty it is to investigate all matters pertaining to criminal abortions.

Election Commission: This committee is composed of four members whose duty it is to conduct all elections, and they also have charge of all matters pertaining to the election.

Constitution and By-Laws Committee: This committee is composed of three members whose duty it is to take care of all changes to the constitution and by-laws. Any change is referred to them, and they then bring in their recommendations to the council.

Public Relations Committee: This committee is composed of three members together with the president and secretary ex-officio. Their duty is to take up all matters of public policy or legislative matters, and the work is carried on in conjunction with the State Legislation Committee on all matters pertaining to the medical profession.

Grievance Committee: This committee is composed of three members whose duty it is to investigate all complaints made against physicians, by the laity as well as by the profession. They are also working in conjunction with the state investigators in an effort to eliminate the "quacks."

There are ten special societies which by vote of the council are recognized as sections of the Chicago Medical Society. They are: the Chicago Neurological Society; Chicago Pathological Society; Chicago Urological Society; Chicago Dermatological Society; Chicago Laryngological and Otological Society; Chicago Pediatric Society; Chicago Orthopedic Society; Chicago Surgical Society; Chicago Ophthalmological Society, and Chicago Academy of Surgery.

Each special or affiliated society holds a meeting each month excepting during July, August and September, so that with the branch societies there are about twenty-five meetings held each month apart from the general society meeting.

The general society last year held thirty-five meetings, and there were 107 papers contributed to the scientific pro-

grams, and 112 men took part in the discussion of these papers.

OTHER MEDICAL ORGANIZATIONS

There are a great number of other medical organizations whose membership is limited to physicians and scientists. They include the Institute of Medicine of Chicago, the Chicago Society of Internal Medicine, and a Physicians' Club—a social organization.

TRANSPORTATION

On account of conditions incident to the war, it is impossible to announce any special railroad rates for the convention. The facilities of the railroads are being taxed to the utmost in moving troops, munitions, fuel and food. For the same reason extra train service is being restricted. Delegates coming to the convention from the Pacific Coast, according to information received from the Transcontinental Passenger Association, may take advantage of the regular nine months' excursion fares which are in effect daily from Pacific Coast common points to Chicago. These tickets are sold at a substantial reduction from double the one-way fares. Examples of some of the rates are: from *California* to Chicago and return, $110; from North Pacific Coast common points to Chicago and return, $100. These tickets are sold from California, Nevada, Oregon, Washington and British Columbia.

THE HOME OF THE ASSOCIATION

The Association headquarters are located at the corner of North Dearborn Street and Grand Avenue, easily accessible from the business district of the city. During the annual session, arrangements will be available for conducting visiting physicians through the building and giving information relative to the conduct of the work. The offices of the Association are open from 8 a. m. to 5 p. m.

ACCOMMODATIONS OFFERED BY CHICAGO HOTELS

The local Committee on Arrangements, on recommendation of its subcommittee on hotels, urges that those who plan to attend the Chicago session, June 10 to 14, should make their selection and write directly to the hotel, stating the accommodations desired and indicating the rate they are prepared to pay. The management of the hotel should be advised of the day on which guests expect to arrive in Chicago, and the length of time they plan to remain. If, in any instance, a satisfactory arrangement with some one of the hotels is not made, write to the chairman, subcommittee on hotels, Dr. C. J. Whalen, 25 East Washington Street, Chicago.

The accompanying table lists a number of Chicago hotels indicating the accommodations which are offered and naming the rates per day. All rates are for accommodation on the European plan except when, as indicated, the American plan is offered.

MEETING PLACES AND HOTEL HEADQUARTERS

The following hotels have been designated as general and section headquarters for the Chicago Session, June 10 to 14:

General Headquarter: Hotel Sherman, North Clark and West Randolph.

Practice of Medicine: Hotel Morrison, 83 West Madison.

Surgery, General and Abdominal: Auditorium Hotel, 430 South Michigan.

Obstetrics, Gynecology and Abdominal Surgery: Congress Hotel, South Michigan and Congress.

Ophthalmology: Hotel LaSalle, LaSalle and West Madison.

Laryngology, Otology and Rhinology: Hotel LaSalle, LaSalle and West Madison.

Diseases of Children: Congress Hotel, South Michigan and Congress.

Pharmacology and Therapeutics: Auditorium Hotel, 430 South Michigan.

Stomatology: Congress Hotel, South Michigan and Congress.

Nervous and Mental Diseases: Blackstone Hotel, South Michigan and East Seventh.

Dermatology: Blackstone Hotel, South Michigan and East Seventh.

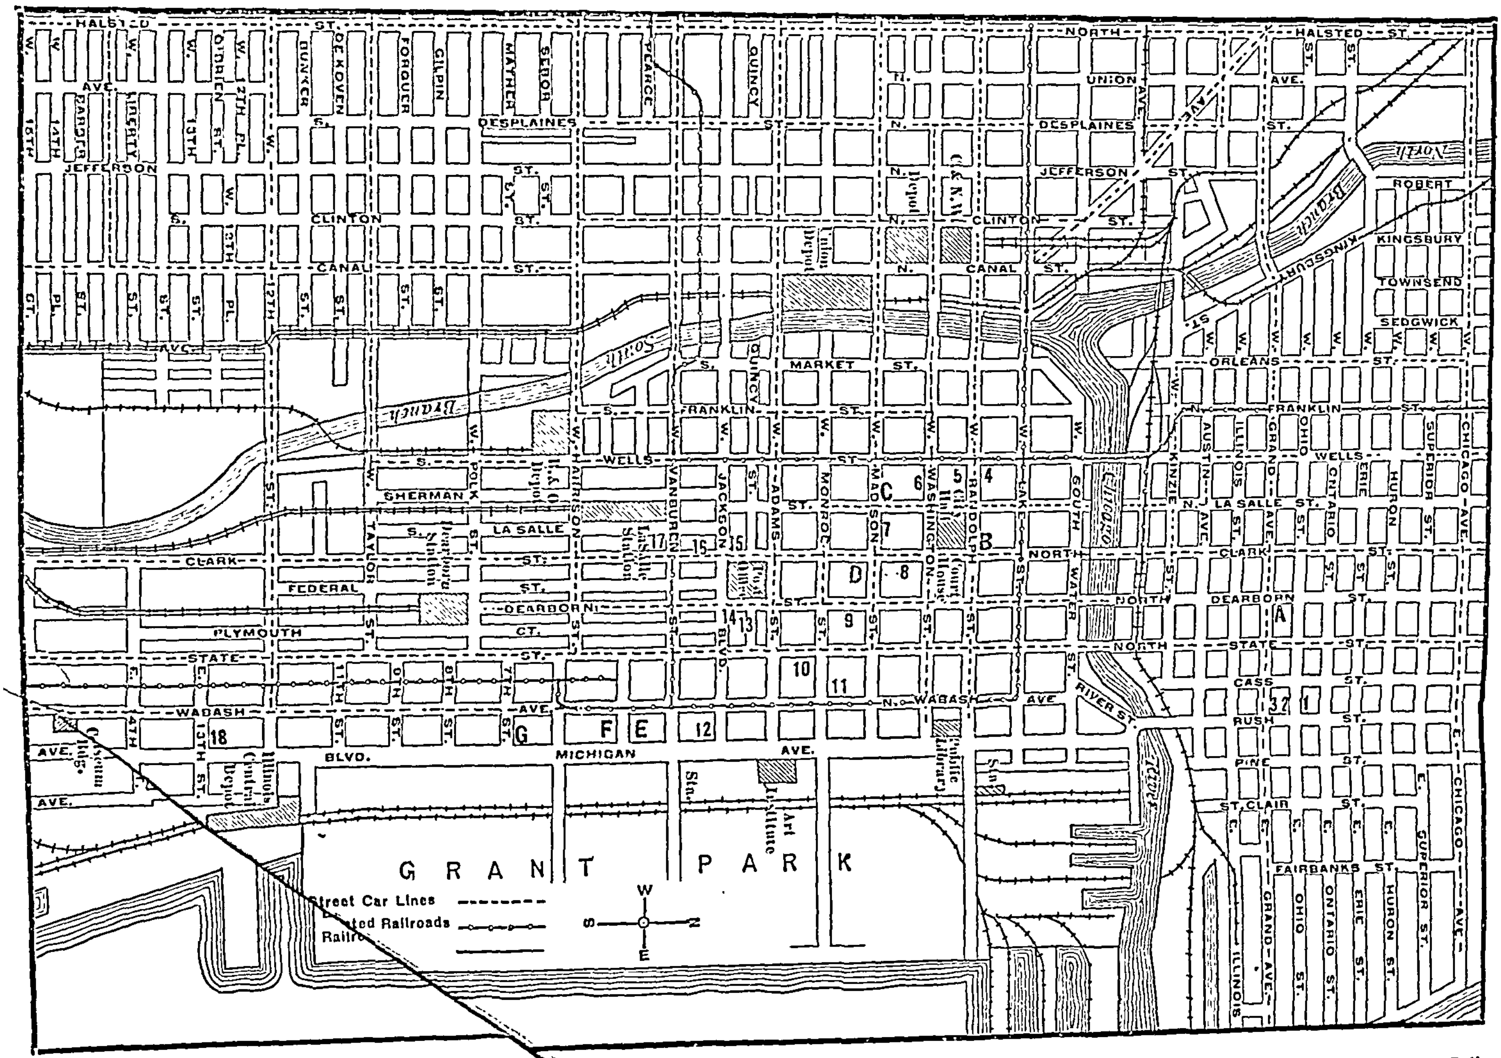
Preventive Medicine and Public Health: Auditorium Hotel, 430 South Michigan.

Genito-Urinary Diseases: Auditorium Hotel, 430 South Michigan.

Orthopedic Surgery: Congress Hotel, South Michigan and Congress.

Gastro-Enterology and Proctology: Auditorium Hotel, 430 South Michigan.

Scientific Exhibit, Registration Bureau, Commercial Exhibit, Information Bureau, and Branch Post-office: Hotel Sherman, North Clark and West Randolph.



A—American Medical Association Building, 535 N. Dearborn St., N. E. Cor. Grand Ave. and Dearborn St.

B—Hotel Sherman, N. W. Cor. Clark and Randolph Sts.

C—Hotel LaSalle, N. W. Cor. LaSalle and Madison Sts.

D—Morrison Hotel, 83 W. Madison St., S. E. Cor. Clark and Madison Sts.

E—Auditorium Hotel, 430 S. Michigan Blvd., N. W. Cor. Michigan Blvd. and Congress St.

F—Congress Hotel and Annex, S. W. Cor. Michigan Blvd. and Congress St.

G—The Blackstone, N. W. Cor. Michigan Blvd. and E. Seventh St.

1. Virginia Hotel, N. W. Cor. Rush and Ohio Sts.
2. Hotel Alexandria, 542 Rush St., S. W. Cor. Rush and Ohio Sts.
3. Hotel Bradley, 536 Rush St., N. W. Cor. Rush St. and Grand Ave.
4. Briggs House, 188 W. Randolph St., N. E. Cor. Wells and Randolph Sts.
5. Hotel Bismarck, 171 W. Randolph St., south side, between Wells and LaSalle Sts.
6. Hotel Washington, 167 W. Washington St., south side, between Wells and LaSalle Sts.
7. Hotel Brevoort, 120 W. Madison St., north side, between LaSalle and Clark Sts.
8. Hotel Planters, 19 N. Clark St., east side, between Washington and Madison Sts.
9. Saratoga Hotel, *23-29 S. Dearborn St.*, east side, between Madison and Monroe Sts.
10. Palmer House, S. E. Cor. State and Monroe Sts.
11. Windsor-Clifton Hotel, 39 S. Wabash Ave., N. W. Cor. Wabash Ave. and Monroe St.
12. Stratford Hotel, N. W. Cor. Jackson and Michigan Blvds.
13. Hotel Majestic, 29 Quincy St., south side, between State and Dearborn Sts.
14. Great Northern Hotel, Jackson, Quincy and Dearborn Sts., N. E. Cor. Dearborn St. and Jackson Blvd.
15. Grand [illegible] Jackson Hotel, 232 S. Clark St., N. W. Cor. Clark St. and Jackson Blvd.
16. Hotel Atlantic, [illegible] S. Clark St., west side, near Jackson Blvd.
17. Fort Dearborn [illegible] 125 W. Van Buren St., S. E. Cor. LaSalle and Van Buren.
18. New Southern Hotel, [illegible] Michigan Ave., N. W. Cor. Michigan Blvd., and Thirteenth.

REGISTRATION

The Importance of Registering Early—A Few Suggestions Which Will Facilitate Registration

The Bureau of Registration will be located in the Louis XVI Room, Sherman Hotel, Randolph and Clark Streets. A committee of local physicians will assist those desiring to register. A branch postoffice will be opened, and a bureau of information established in connection with the Registration Bureau.

Every one who registers will be required to fill out completely, except the blank space for the number, the spaces on both parts of the double registration cards, which will be found on the tables in front of the Registration Bureau. These entries should be written very plainly, or printed, as the cards are given to the printer to use as "copy" for the *Daily Bulletin*.

1. Fellows who have their pocket cards with them can be registered with little or no delay. They should present the filled out registration card, together with their pocket card, at one of the windows marked "Registration by Pocket Card." There the clerk will compare the two cards, stamp the pocket card and return it, and supply the Fellow with a copy of the official program and other printed matter of interest to those attending the annual session.

2. Those Fellows who have forgotten their pocket cards should present the filled in registration card at the window marked "Paid—No Card." The work of registration at this window will be conducted as rapidly as possible; but the necessity of finding the Fellow's name on the Fellowship roster will occupy time and will occasion inconvenience to those who neglect to bring their pocket cards with them.

3. The Fellow whose 1918 dues are unpaid should present his filled in registration card with the amount of his Fellowship dues ($5) at one of the windows marked "Cash." Here, too, there will be occasioned some delay; but the work of registering will be conducted as promptly as possible.

4. Subscribers and others desiring to qualify as Fellows should present a filled in registration card, together with a formal application for Fellowship at the window marked "New Fellows." These applications for Fellowship can be obtained at Window No. 1 of the Registration Bureau or from the members of the Committee on Registration. In order to qualify as a Fellow, the applicant must be officially reported as a member of the constituent association of the state in which he resides, and in addition to filing this formal application, he must pay his annual Fellowship dues for the current year; if already a subscriber to THE JOURNAL, with his subscription paid for a term to or beyond Jan. 1, 1919, no additional payment is necessary. If subscription is not paid in full for the current year, the payment of a sum to extend it to Jan. 1, 1919 is required.

The registration of new Fellows will be greatly facilitated if they will provide themselves with certificates of membership issued by the secretary of their state association, certifying to their membership in the state and county branches of the organization.

It will assist in registering if those who desire to qualify as Fellows will file their applications and qualify as Fellows by writing directly to the American Medical Association, 535 North Dearborn Street, Chicago, so that their Fellowship may be entered not later than June 1. Any applications received later than June 1 will be given prompt attention, but the Fellowship certificate and pocket card may not reach the applicant in time so that he can use this card in registering at the Chicago session, and he may be required to make a second payment of his Fellowship dues, which must be held until the records at headquarters can be consulted after the close of the session, when any excess payment will be adjusted.

If, however, a member of the Association neglects to qualify as a Fellow before reaching Chicago, he may be entered as a Fellow at the meeting, as suggested above.

POSTOFFICE

An Association Postoffice will be maintained at the Registration Bureau in the Louis XVI Room, Sherman Hotel, Randolph and Clark Streets. Guests are requested to order mail addressed to them "Care American Medical Association, Sherman Hotel, Chicago," or to their hotels, as preferred.

CLINICS AT CHICAGO SESSION

Extensive preparation for clinics in connection with the Chicago session has been made. Clinics will be given every day for five days beginning Thursday, June 6, and ending Tuesday, June 11.

The Local Committee of Arrangements appointed the following committee on clinics: Charles E. Humiston, chairman; Karl E. Meyer, secretary; E. Wyllys Andrews, Daniel Eisendrath, Thomas L. Gilmer, Joseph B. DeLee, A. J. Ochsner, Wilbur E. Post, Hollis E. Potter and Bertram W. Sippy.

This supervising committee called to its assistance representatives of the various hospitals and medical educational institutions of Chicago. A subcommittee for each specialty was selected and in addition a special committee of one for each hospital was chosen who was made responsible for the clinics and demonstrations in his own particular institution.

These clinics are presented for the benefit of the members of the American Medical Association and there is no charge or fee of any kind for the privilege of attending any of them. The "Pocket Card" or other evidence of membership in the Association is the "ticket" of admission.

A comprehensive schedule has been prepared covering the entire field of medicine and surgery. All specialties will be represented in one or more hospitals every day of the entire five day period.

The preliminary publication in this issue is necessarily incomplete. Details and hours of each clinic will be published in ample time for the guidance of those who are interested.

Autopsies at the Cook County Morgue both morning and afternoon will be held every day.

In order that proper steps may be taken to care for the interests of all visiting fellows the committee wishes to ascertain in advance the probable attendance and accordingly requests those who contemplate attending these clinics to inform the chairman as soon as convenient.

ALEXIAN BROTHERS HOSPITAL, 1200 Belden Ave.—*General Surgery:* M. L. Harris, Wm. E. Hesser and A. Zimmerman. *Genito-Urinary:* L. Diamesis, Herman L. Kretschmer, L. E. Schmidt and E. White. *Eye, Ear, Nose and Throat:* J. Holinger. *Medicine:* H. Klein and A. Luckhardt. *Nervous and Mental:* A. B. T. Heym.

AUGUSTANA HOSPITAL, 2043 Cleveland Ave.—*General Surgery:* A. T. Lundgren, A. J. Ochsner and H. M. Percy. *Medicine:* Frank Smithies.

CHICAGO STATE HOSPITAL, Dunning Station.—*Nervous and Mental:* H. Douglas Singer.

CHICAGO POLICLINIC AND HOSPITAL, 221 W. Chicago Ave.—*General Surgery:* J. A. Graham, M. L. Harris, Wm. Hessert and C. C. Rogers. *Gynecology:* C. V. Bachelle. *Orthopedics:* E. W. Ryerson. *Eye, Ear, Nose and Throat:* C. H. Francis, Otto T. Freer, J. W. Mahoney and C. M. Robertson. *General Medicine:* J. F. Hultgen and E. S. Moore. *Tuberculosis:* O. W. McMichael. *Pediatrics:* Paul Grabow. *Stomach:* A. Heinen. *Obstetrics:* C. S. Bacon. *Genito-Urinary:* Robert H. Herbst.

THE CHICAGO FRESH AIR HOSPITAL, Cor. Howard and Western Ave.—*Tuberculosis:* Pneumothorax Treatment, Ethan Allen Gray.

CHILDREN'S MEMORIAL HOSPITAL, 735 Fullerton Ave.—*General Surgery:* Coleman G. Buford, John Graham and Robert O. Ritter. *Orthopedic:* Robert O. Ritter. *Eye, Ear, Nose and Throat:* David Fiske, Edwin Norcross and John Williams. *Medical:* Arthur Parmalee and Samuel J. Walker. *Infant Feeding:* George Edwin Baxter.

CHICAGO LYING-IN HOSPITAL, 426 E. 51st St.—*Obstetrics:* C. S. Bacon, J. B. DeLee, H. M. Stowe and Anna Lapham.

COOK COUNTY HOSPITAL, Harrison and Wood Sts.—*General Surgery:* E. Wyllys Andrews, Charles Davison, Frederick G. Dyas, Daniel N. Eisendrath, Charles E. Humiston, Harry Jackson, A. Belcham Keyes, Paul F. Morf, Arthur B. Rankin, Harry Richter, Lawrence Ryan, Victor

L. Schrager, Geo. F. Thompson, Roger T. Vaughan and John A. Wolfer. *Gynecology:* Mary McEwen, H. M. Stowe, Bertha VanHoosen and Wesley J. Woolston. *Orthopedics:* Charles M. Jacobs, Charles A. Parker and Henry B. Thomas. *Eye, Ear, Nose and Throat:* Joseph C. Beck, G. W. Boot, E. V. L. Brown, J. W. Clark, Charles G. Darling and Robert Sonnenschein. *Genito-Urinary:* Frederick G. Harris, Ernest L. McEwen and Arthur W. Stillians. *Medicine:* Arrie Bamburger, Arthur F. Beifeld, Wm., J. Butler, Leon Bloch, James G. Carr, Harry B. Culver, W. W. Dicker, A. A. Goldsmith, Karl K. Koessler, Ludwig M. Loeb, M. Milton Portis, Joseph M. Patton, S. R. Slaymaker, Frederick Tice and Theodore Tieken. *Nervous and Mental:* Julius Grinker, George W. Hall, George B. Hassin and Sigmund Krumholz. *Tuberculosis:* Max Beisenthal, Frank Chauvet, J. F. Hultgen, Maurice Lewison, Wm. Ed. Putz, Katherine B. Rich and Isadore M. Trace. *Pediatrics:* May Michaels and August Strauch. *Obstetrics:* Frederick O. Bowe, Frederick H. Falls and Otto H. Rohrlack. *Pathology:* D. J. Davis, Ludvig Hektoen, E. R. LeCount, J. Simonds and H. Gideon Wells. *Contagious Diseases:* Maurice Blatt, Archibald L. Hoyne and H. E. Irish. *Oral Surgery:* Louis Schults and Herbert Potts.

Frances Willard Hospital, 710 S. Lincoln St.—*General Surgery:* Hugh N. MacKechnie, Lawrence Ryan, V. L. Schrager and Allen Stewart. *Eye, Ear, Nose and Throat:* W. D. Brode and L. B. Phelps. *General Medicine:* Wm. J. Butler and V. L. Sheets. *Stomach:* M. H. Mack. *Roentgen Ray:* B. H. Orndoff. *Oral Surgery:* T. W. Brophy.

Hahnemann Hospital, 2814 Ellis Ave.—*Surgery:* H. R. Chislett and Chas. E. Kahlke.

Home for Destitute Crippled Children, 1653 Park Ave.—*Surgery:* Ed. McGinnis. *Orthopedic:* Wallace Blanchard and Chas. A. Parker.

The Illinois Charitable Eye and Ear Infirmary, 904 W. Adams St.—*Eye:* W. A. Barr, Robt. H. Buck, David Evans, Michael Goldenberg, Louis G. Hoffman, Arthur P. Hunneman, Michael Lebensohn, Dwight C. Orcutt, Nils E. Remmen and Robert Vonder Heydt. *Ear:* Henry R. Boettcher, James R. Davey, S. M. Hager, Alfred Lewy and W. K. Spiece.

Illinois Central Hospital, 5744 Stoney Island Ave.—*General Surgery:* E. J. Hoglund, L. L. Iseman and T. H. Kelly. *Gynecology:* Wm. Cuthbertson. *Eye, Ear, Nose and Throat:* Geo. J. Musgrave and R. J. Tivnen. *General Medicine:* W. T. Harsha. *Roentgen Ray:* B. C. Cushway.

Mercy Hospital, 2537 Prairie Ave.—*General Surgery:* E. Wyllys Andrews, John F. Golden, G. W. Hochrein, P. H. Kreuscher, M. F. McGuire, E. L. Moorhead, Wm. E. Morgan, F. E. Pierce and C. F. Sawyer. *Eye, Ear, Nose and Throat:* G. T. Jordan, G. J. Musgreaves and R. J. Tivnen. *Genito-Urinary:* V. D. Lespinasse. *Medicine:* C. P. Caldwell, J. G. Carr, A. C. Kleutgen, J. M. Lillie, W. G. McGuire and F. Wright. *Nervous:* Julius Grinker. *Gynecology:* W. S. Barnes and W. J. Jeffries. *Pediatrics:* Robt. A. Black and T. J. Sullivan, Jr.

Michael Reese Hospital, 29th and Ellis Ave.—*General Surgery:* E. Wyllys Andrews, Geo. Davenport, Daniel N. Eisendrath, E. Friend and A. A. Straus. *Gynecology:* Emil Ries and L. Frankenthal. *Eye, Ear, Nose and Throat:* Ira Frank and H. Kahn. *Genito-Urinary:* Daniel N. Eisendrath and Gustav Kolischer. *General Medicine:* A. R. Edwards, E. L. Schram, Solomon Strouse and Frank Wright. *Pediatrics:* I. A. Abt and E. Lackner. *Nervous and Mental:* Archibald Church.

Northwestern University Medical School, 2431 S. Dearborn St.—*Nervous and Mental:* Hugh T. Patrick.

Norwegian Deaconess Hospital, 1138 N. Leavitt St.—*General Surgery:* J. R. Ballinger, Svening Dahl, J. V. Fowler, E. E. Henderson and A. Holmboe.

North Chicago Hospital, 2551 N. Clark St.—*General Surgery:* Carl Beck, Emil Beck and B. Katz. *Ear, Nose and Throat:* Joseph Beck and H. L. Pollock. *Roentgen Ray:* Paul Eisen.

Passavant Hospital, 149 W. Superior St.—*Surgery:* E. J. Brougham, Aime Paul Heineck, Frank R. Morton, Carl G. Swenson, O. J. Waters and A. G. Wermuth.

Provident Hospital (colored), 16 W. 36th St.—*General Surgery:* Geo. C. Hall. *Gynecology:* Bertha Van Hoosen. *Eye, Ear, Nose and Throat:* H. R. Smith and E. S. Stewart. *Genito-Urinary:* Albert E. Mowry. *Nervous and Mental:* Albert B. Yudelson. *Pediatrics:* Mark Jampolis and G. W. Prince. *General Medicine:* A. Wilberforce Williams. *Obstetrics:* E. R. Cornell. *Roentgen Ray:* C. D. Bell.

Post Graduate Medical School, 2400 S. Dearborn St.—*General Surgery:* C. J. Drueck, Chas. Frazier, W. J. Marvel, A. W. McNealy, J. C. Salyers and W. J. Sullivan. *Gynecology:* W. F. Dickson, H. L. Meyers, Emil Ries and Henry Scott. *Orthopedics:* R. W. Hardon. *Eye, Ear, Nose and Throat:* M. M. Jones, C. W. Hawley, A. Duncan, E. P. Norcross, Chas. Long, I. Sher, L. E. Schwarz, O. J. Stein and Robt. Sonnenschein. *Genito-Urinary:* Gustav Kolischer and Walter Venn. *Medicine:* F. B. Kirby, Harry Meissler, H. W. Traub, A. A. Jamieson and N. C. Gilbert. *Nervous and Mental:* Julius Grinker. *Pediatrics:* Robt. A. Black, O. J. Rabe and F. B. Combs. *Stomach:* A. A. Goldsmith. *Skin:* P. F. Shaffner.

Presbyterian Hospital, 1753 W. Congress St.—*General Surgery:* Arthur Dean Bevan and Carl B. Davis. *Gynecology:* J. C. Webster and N. S. Heaney. *Eye, Ear, Nose and Throat:* Wm. H. Wilder and Geo. E. Shambaugh. *Genito-Urinary:* Herman L. Kretschmer and Robert Herbst. *Medicine:* J. B. Herrick, B. W. Sippy and W. E. Post. *Nervous and Mental:* Thor Rothstein and Peter Bassoe. *Pediatrics:* Walter Hoffmann. *Skin:* O. S. Ormsby.

Psychopathic Hospital, Wood and Polk Sts.—*Nervous and Mental:* Herman M. Adler, Geo. W. Hall, G. B. Hassin, Julius Grinker, Julius Retinger and Sydney Kuh.

Ravenswood Hospital. 1917 Wilson Ave.—*General Surgery:* G. N. Bussey, Clark A. Buswell, G. W. Green, W. W. Mueller, A. G. Schroeder and J. J. Toeller. *Medicine:* Geo. Edwin Baxter and Josiah J. Moore.

Rush Medical College.—*Nervous and Mental:* James C. Gill and Thor Rothstein. *Genito-Urinary:* Robert H. Herbst.

St. Luke's Hospital, 1439 S. Michigan Ave.—*General Surgery:* E. Wyllys Andrews and L. L. McArthur. *Gynecology:* E. C. Dudley and L. E. Frankenthal. *Orthopedics:* J. L. Porter. *Eye, Ear, Nose and Throat:* F. Allport, Paul Guilford, G. P. Marquis and E. P. Norcross. *General Medicine:* A. R. Elliott and R. B. Preble. *Nervous and Mental:* A. Church. *Pediatrics:* F. X. Walls. *Obstetrics:* C. E. Paddock. *Oral Surgery:* T. L. Gilmer.

St. Bernard's Hospital, 6337 Harvard Ave.—*General Surgery:* J. C. Belson, W. H. Bohart, Carl Christoph, O. E. Christoph, G. M. Cushing, J. C. Hepburn, Henry Hoffman, J. B. Haeberlin, W. J. Hurley, Frederick Lofton, J. T. Meyers and Jacobson. *Eye, Ear, Nose and Throat:* *Austin A. Hayden* .

St. Joseph's Hospital, 2100 Burling St.—*General Surgery:* Wm. Hessert and Carl Wagner. *Gynecology:* Wallace Grosvenor. *Eye, Ear, Nose and Throat:* John B. Ellis, Austin Hayden, J. Holinger and J. Z. Bergeron. *Roentgen Ray:* Isadore Trostler. *Oral Surgery:* Truman Brophy.

Wesley Hospital, 2449 S. Dearborn St.—*General Surgery:* H. M. Richter, Wm. E. Schroeder, W. E. Shackleton and John A. Wolfer. *Gynecology:* Mark T. Goldstine. *Ear:* J. Gordon Wilson. *Medicine:* Achilles Davis, Chas. A. Elliott, N. C. Gilbert, A. A. Goldsmith, C. P. Horner and L. J. Osgood. *Obstetrics:* Charles B. Reed.

The University Hospital, Ogden Ave., Congress and Lincoln Sts.—*General Surgery:* Charles Davison. *Orthopedics:* Edwin W. Ryerson. *Eye, Ear, Nose and Throat:* E. V. L. Brown and Wm. E. Gamble. *Genito-Urinary:* Harry Culver. *Medicine:* Ed. L. Heintz. *Pediatrics:* Henry E. Irish. *Obstetrics:* Chas. S. Bacon.

Washington Boulevard Hospital, 2449 Washington Blvd.—*Surgery:* B. F. Lounsbury.

West Suburban Hospital, Ontario St. and Austin Ave., Oak Park (City limits, West).—*General Surgery:* Chas. E. Humiston.

West Side Hospital, 1844 W. Harrison St.—*General Surgery:* E. M. Brown, T. A. Davis, Paul Gronnerud, C. C. O'Byrne and Geo. F. Thompson. *Gynecology:* A. N. Claggett and J. M. Lang. *Eye, Ear, Nose and Throat:* James A. Clark and Wm. L. Noble. *Genito-Urinary:* John S. Nagel. *General Medicine:* W. L. Callaway. *Nervous and Mental:* C. N. King. *Skin:* K. A. Zurawski and Robt. A. Sempill.

AMERICAN MEDICAL GOLFING ASSOCIATION

The fourth tournament of the American Medical Golfing Association will be held on June 10 at the Glenview Golf Club. The following members of the local committee and section captains will be in charge of the entertainment: Section on Surgery—Arthur Bevan; Section on Practice of Medicine—John Dodson; Section on Surgery, Gynecology and Obstetrics—Thomas Watkins; Section on Dermatology—William Pusey; Section on Ophthalmology— Frank Brawley; Eye, Ear, Nose and Throat Section—Frederick Menge; Section on Pediatrics—Henry Helmholtz; Section on Orthopedics—Edwin Ryerson; Section on Pathology—Gideon Wells. Fellows of the American Medical Association who wish to enter the tournament should communicate without delay with the secretary, Dr. Will Walter, 1414 Chicago Avenue, Evanston, Ill. Visiting foreign surgeons are invited to attend the tournament.

MEETINGS FOR WOMEN PHYSICIANS

Sunday Afternoon, June 9, 3 p. m., a tea at the South Shore Country Club.

Tuesday, June 11, 12 m.-1 p. m., assembly room of the Chicago College Club, Dr. Mabel S. Ulrich of Minneapolis will speak on social hygiene.

Wednesday, June 12, 5:30 p. m. Banquet for medical women at La Salle Hotel.

Headquarters

Headquarters have been engaged at the Chicago College Club in the Stevens' Building. Luncheon and supper will be served in the club; there are reception and rest rooms; our guests can have their mail forwarded here, receive their friends, get telephone messages and rest between sessions.

Reservations

The Medical Women's Committee (Dr. Clara P. Seippel, chairman, 25 East Washington Street, Chicago) will be glad to be of service to women physicians who attend the convention. An entire floor of rooms has been reserved at the Hotel La Salle. They request that every medical woman who intends to be in Chicago from June 6 to 14 send them her name, address while in the city, and time of arrival, so that she may be notified of any gatherings.

THE SCIENTIFIC EXHIBIT

The Scientific Exhibit will occupy the mezzanine floor of Hotel Sherman. This is in direct contact with the general headquarters and the commercial exhibit, and is easily accessible to the visiting physicians. The exhibits promise to be unusually interesting as there are several of special military interest. In connection with many of the exhibits frequent demonstrations by especially qualified persons will be provided. One gold and two silver medals and several certificates of merit will be awarded for the exhibits which are adjudged most worthy. The following exhibits have already been arranged for:

DR. V. D. LESPINASSE, Chicago, Ureteral Stone—pictures, slides and specimens.

DR. DANIEL N. EISENDRATH, Chicago—1. Experimental effects of cholecystectomy. 2. Anatomy of common duct region. 3. Specimens of kidney surgery.

DR. LEIGH F. WATSON, Chicago—Experimental studies of goiter, specimens, photographs and photomicrographs.

DR. HENRY F. SMYTH, Laboratory of Hygiene, University of Pennsylvania—Industrial Dust—charts, photographs and museum specimens.

DR. ALFRED A. STRAUSS, Chicago—Stomach and intestinal surgery—operation for sterility in male.

DR. HIDEYO NOGUCHI, Rockefeller Institute, New York—Spirochaeta of infectious jaundice.

DR. EMIL G. BECK, Chicago—Stereoscopic roentgenographs illustrating localization of foreign bodies and lung abscess.

PRUDENTIAL LIFE INSURANCE COMPANY OF AMERICA, Newark, N. J.—Malaria eradication and control.

MAYO FOUNDATION, Rochester, Minn.—Selected exhibit.

MARY THOMPSON HOSPITAL, Chicago—Anesthetic cap and berthe, delivery bed, bedside cabinet, examining glove, hospital window and pictures.

FORT RILEY SANITARY LABORATORY, Fort Riley, Kan.—Army sanitation—fifty models of Army sanitary apparatus.

Introduction and Installation of President-Elect ARTHUR DEAN BEVAN, Chicago.

Address. DR. ARTHUR DEAN BEVAN.

Music.

GENERAL MEETING, WEDNESDAY EVENING

Military Meeting

Plans are being perfected for a general meeting to be held on Wednesday evening, June 12, at 8:30, at which representatives of the Medical Corps of our allied nations, together with other distinguished medical guests, will speak on medical war problems.

THURSDAY EVENING MEETING

Patriotic Meeting

A general popular patriotic war meeting will be held in the Auditorium Theater on Thursday evening at 8:30, when distinguished citizens of Chicago will present the appeal of the United States in the present war from the viewpoint of loyal citizenship.

THE PROGRAMS OF THE SECTIONS

Outline of the Scientific Proceedings — The Preliminary Program and the Official Program

The following papers are announced to be read before the various sections. The order here is not necessarily the order which will be followed in the Official Program nor is the list complete. The Official Program will be a pamphlet similar to those issued in previous years, and will contain the final program of each section with abstracts of the papers, also lists of committees, programs of the General Meeting and of the meetings of the House of Delegates, lists of entertainments, map of Chicago and other information. To prevent misunderstandings and to protect the interest of advertisers, it is here announced that this Official Program will contain no advertisements. It is copyrighted by the American Medical Association and will not be distributed before the session. A copy will be given to each member on registration.

SECTION ON MISCELLANEOUS TOPICS

MEETS IN AUDITORIUM THEATER

OFFICERS OF SECTION

Chairman—FRANK BILLINGS, Chicago
Vice Chairman—JAMES BORDLEY, JR., Baltimore.
Secretary—HARRY E. MOCK, Chicago.

Thursday, June 13—9 a. m.

1. Opening Address.
   WILLIAM C. GORGAS, Washington, D. C.
2. Chairman's Address: The National Program for the Reconstruction and Rehabilitation of the Disabled Soldiers. FRANK BILLINGS, Chicago.
3. Reconstruction and Rehabilitation Problems as Demonstrated by Experience in Foreign Countries.
   CASEY A. WOOD, Chicago.

12. "The Way Out": Educational Propaganda for the Disabled Soldiers and for the Public (Illustrated by Motion Pictures). Arthur H. Samuels, Washington, D. C., and Michael J. Dowling, Olivia, Minn.

SECTION ON PRACTICE OF MEDICINE

MEETS IN BANQUET ROOM, HOTEL MORRISON

OFFICERS OF SECTION

Chairman—Lawrence Litchfield, Pittsburgh.
Vice Chairman—A. W. Hewlett, San Francisco.
Secretary—James S. McLester, Birmingham, Ala.
Executive Committee—Thomas McCrae, Philadelphia; Roger S. Morris, Cincinnati; Henry A. Christian, Boston.
(Stenographer—Dr. W. W. Bellamy, Boston)

Wednesday, June 12—9 a. m.

1. Chairman's Address: Dextrose Intravenously as a Therapeutic Agent. Lawrence Litchfield, Pittsburgh.
2. War and Medical Education. Horace D. Arnold, Boston.
3. Further Studies in the Treatment of Acute Poliomyelitis with Immune Horse Serums. Edward C. Rosenow, Rochester, Minn.
4. Pulmonary Compression Signs Associated with Fibrinous Pericarditis. Henry A. Christian, Boston
5. On Ulceration of the Soft Palate Resembling Syphilitic Perforating Ulcer Due to Fusiform Bacilli and Spirillae (Vincent's Angina). Sydney R. Miller, Baltimore.

   Discussion to be opened by Roger S. Morris, Cincinnati, and Frank J. Sladen, Detroit.
6. The Complications of Cerebrospinal Meningitis and Their Treatment. William W. Herrick, New York.

Wednesday, June 12—2 p. m.

7. Measles in the Army Camp.
8. Report on Cases of Cerebrospinal Meningitis (Epidemic) Observed at General Hospital No. 6, Fort McPherson, Ga. Charles N. B. Camac, New York, and Karl M. Bowman, White Plains, N. Y.
9. Neurocirculatory Asthenia. William H. Robey, Jr., Boston.
10. The Training of the Medical Officers in the Army. William N. Bispham, Fort Riley, Kan.
11. The Significance of Presystolic Thrills in the Examination of Recruits. Roger S. Morris and Alfred Friedlander, Cincinnati.
12. Newer Aspects of Digitalis Therapy. Joseph H. Pratt, Boston.

    Discussion to be opened by Alfred E. Cohn, Washington, D. C., and George Canby Robinson, St. Louis.

Thursday, June 13

THIS SECTION WILL HOLD NO MEETING ON THIS DAY, BUT WILL JOIN WITH THE SECTION ON MISCELLANEOUS TOPICS

Friday, June 14—9 a. m.

Election of Officers

SYMPOSIUM ON PNEUMONIA

13. A Clinical Study of Eight Hundred Cases of Pneumonia. Willard J. Stone, Toledo, Ohio.
14. Unique Findings Gathered from the Observation of Eleven Hundred Cases of Pneumonia in a Base Hospital. Arthur A. Small, Chicago.
15. An Epidemic of Streptococcus Pneumonia and Empyema at Camp Dodge. Joseph L. Miller and Frank B. Lusk, Chicago.
16. Streptococcus Pneumonia. James G. Cumming, Ann Arbor, Mich.
17. The Pathology of the Pneumonia of the Army Camp. William G. MacCallum, Baltimore.
18. Practical Consideration of Epidemiology Drawn from a Classification of Streptococci. Ralph A. Kinsella, St. Louis.

    Discussion to be opened by Ernest E. Irons, Chicago; Rufus I. Cole, New York; Bruce G. Phillips, New York; Walter P. Bliss, New York; Hugh McKenna, Chicago, and George F. Dick, Chicago.

Friday, June 14—2 p. m.

19. Acute Mastoiditis as a Complication of Infectious Diseases. George H. Lathrope, Morristown, N. J.

    Discussion to be opened by William H. Robey, Jr., Boston, and Robert H. Fowler, New York.
20. The Prevention and Control of Contagious Diseases. Joseph A. Capps, Chicago.
21. Later Results of the Intraspinous Treatment of Cerebrospinal Syphilis, Based on Four Years' Observation. Clyde L. Cummer, Cleveland, and Richard Dexter, Toledo, Ohio.

    Discussion to be opened by John A. Fordyce, New York.
22. A Study of Diaphragmatic Movements in Acute Abdominal Inflammations. Llewellyn Sale, St. Louis.

SECTION ON SURGERY, GENERAL AND ABDOMINAL

MEETS IN AUDITORIUM THEATER

OFFICERS OF SECTION

Chairman—E. Starr Judd, Rochester, Minn.
Vice Chairman—Robert C. Coffey, Portland, Ore.
Secretary—Eugene H. Pool, New York.
Acting Secretary—George P. Müller, Philadelphia.
Executive Committee—Charles H. Peck, New York; E. Wyllys Andrews, Chicago; William D. Haggard, Nashville, Tenn.
(Stenographer—Mrs. M. C. Repp, Philadelphia)

Wednesday, June 12—9 a. m.

1. Chairman's Address. E. Starr Judd, Rochester, Minn.
2. Congenital Cleft Palate and Harelip. Truman W. Brophy, Chicago.

   Discussion to be opened by A. J. Ochsner, Chicago.
3. The Principles of Thyroid Surgery. Charles H. Mayo, Rochester, Minn
4. Temporary Loss of Voice Following Thyroidectomy. Donald Guthrie, Sayre, Pa.
5. Goiter in the Southeast. Edward G. Jones, Atlanta, Ga.

   Discussion on the foregoing papers by Charles H. Frazier, Philadelphia; Stuart McGuire, Richmond, Va.; Emil Goetsch, Baltimore, and Gordon B. New, Rochester, Minn.
6. On Glycophilia. Willy Meyer, New York.

   Discussion to be opened by Leo Buerger, New York.

Wednesday, June 12—2 p. m.

7. Reconstruction of the Common Duct from the Experimental Standpoint.
J. Shelton Horsley, Richmond, Va.
Discussion to be opened by William J. Mayo, Rochester, Minn. and W. W. Mattson, Tacoma, Wash.

8. Clinical Report on Reconstruction of the Common and Hepatic Ducts. LeGrand Guerry, Columbia, S. C.
Discussion to be opened by James F. Mitchell, Washington, D. C., and Stuart McGuire, Richmond, Va.

9. Rôle of the Cystic Duct in Recurring Cholecystitis.
J. Earl Else, Portland, Ore.
Discussion to be opened by Allen B. Kanavel, Chicago.

10. Traumatic Pancreatic Cysts.
John A. Hartwell, New York.
Discussion to be opened by George D. Stewart, New York.

11. Chronic Pancreatitis Associated with Cholecystitis and Cholelithiasis. Allen O. Whipple, New York.

12. The Ultimate Results in Cases of Chronic and Subacute Pancreatitis.
Edward W. Archibald, Montreal Canada.
Discussion on the foregoing two papers will be opened by John B. Deaver, Philadelphia.

Thursday, June 13

THIS SECTION WILL HOLD NO MEETING ON THIS DAY, BUT WILL JOIN WITH THE SECTION ON MISCELLANEOUS TOPICS

Friday, June 14—9 a. m.

Election of Officers

13. The Therapeutics of Tetanus.
Hermann B. Gessner, New Orleans.
Discussion to be opened by A. P. C. Ashhurst, Philadelphia.

14. Treatment of Suppurative Arthritis by Irrigation and by Staining with Gentian Violet.
John W. Churchman, New Haven, Conn.
Discussion to be opened by George P. Müller, Philadelphia, and Walton Martin, New York.

15. The Use of Dichloramin-T and Other Antiseptics in War Surgery. W. Estell Lee, Philadelphia.

16. The Hodgen Extension Suspension Splint and Its Exemplication in Both Civil and War Surgery.
Frank G. Nifong, Columbia, Mo.

17. A Method for the Relief of Medullary Pressure in Fracture of the Skull. John E. Jennings, Brooklyn.

18. The Fall of the Alkaline Reserve Under Surgical Conditions: Its Effects and Prevention.
Howard W. Haggard, New Haven, Conn.
Discussion to be opened by Carl Wiggers, New York.

Friday, June 14—2 p. m.

19. The Bearing of Hypertonic Sphincters on the Surgery of the Alimentary Tract.
Edward Martin, Philadelphia.

20. Duodenal Fistula and Its Treatment.
Daniel Fiske Jones, Boston.
Discussion to be opened by E. Starr Judd, Rochester, Minn.

21. Gastroptosis: Its Cause, Prevention and Care, with Special Reference to the Duret-Rovsing Operation.
George N. Kreider, Springfield, Ill.
Discussion to be opened by Carl E. Black, Jacksonville, Ill.

22. A New Principle in the Surgical Treatment of Brain Tumors. Arthur C. Strachauer, Minneapolis.
Discussion to be opened by Charles H. Frazier, Philadelphia.

23. Kondoléon's Operation.
Walter E. Sistrunk, Jr., Rochester, Minn.
Discussion to be opened by Rudolph Matas, New Orleans, and Carl B. Davis, Chicago.

24. End-Results in Hodgkin's Diseases.
Ralph E. Morter, Milwaukee.
Discussion to be opened by Charles H. Bunting, Madison, Wis

SECTION ON OBSTETRICS, GYNECOLOGY AND ABDOMINAL SURGERY

MEETS IN GOLD ROOM, CONGRESS HOTEL

OFFICERS OF SECTION

Chairman—Brooke M. Anspach, Philadelphia.
Vice Chairman—Roland E. Skeel, Cleveland.
Secretary—Sidney A. Chalfant, Pittsburgh.
Executive Committee—Thomas S. Cullen, Baltimore; Edward Reynolds, Boston; Howard W. Longyear, Detroit.

(Stenographer—Miss Lidie C. Alexander, Philadelphia)

Wednesday, June 12—9 a. m.

1. Chairman's Address: Enterostomy and Enterocolostomy in the Treatment of Intestinal Obstruction Following Pelvic Operations.
Brooke M. Anspach, Philadelphia.

2. The Clinical Observations and Results of the Newer Methods of Operations in Congenital Pyloric Stenosis and Gastric and Duodenal Ulcers (Lantern Demonstration). Alfred A. Strauss, Chicago.

3. Hypertrophic Pyloric Stenosis in Infancy (Lantern Demonstration).
William D. Haggard, Nashville, Tenn.
Discussion to be opened by Frank X. Walls and Weller Van Hook, Chicago.

4. The Relation of Anomalies of the Bile Ducts and Blood Vessels to Accidents in Biliary Surgery.
Daniel N. Eisendrath, Chicago.

5. Secondary Tuberculous Peritonitis.
William J. Mayo, Rochester, Minn.
Discussion to be opened by Albert J. Ochsner, Chicago.

6. Abdominal Visceropexy: An Original Method With a Report of Cases. J. Riddle Goffe, New York.
Discussion to be opened by C. A. L. Reed, Cincinnati.

7. The Use of the Rubber Band in Abdominal Surgery.
John W. Keefe, Providence, R. I.

Wednesday, June 12—2 p. m.

8. Goiter in Pregnancy (Lantern Demonstration).
Leigh F. Watson, Chicago.
Discussion to be opened by James W. Markoe, New York.

9. Extending the Care of Pregnancy.
Isadore L. Hill, New York.
Discussion to be opened by Barton Cooke Hirst, Philadelphia.

10. Uterine Inertia: Summary of a Series of Cases.
Paul Titus, Pittsburgh.
Discussion to be opened by Rudolph W. Holmes, Chicago.

11. The Use and Abuse of Pituitary Solution.
George W. Kosmak, New York.
Discussion to be opened by J. B. De Lee, Chicago.

12. Pus in the Female Pelvis: A Surgical Retrospect.
John Young Brown, St. Louis.

13. Rectal Section for Pelvic Abscess (Lantern Demonstration). Harry P. Ritchie, St. Paul.

14. Parotitis Following Induced Abortion in a Case of Pernicious Vomiting in Pregnancy.
W. P. Manton, Detroit.
Discussion to be opened by W. A. N. Dorland, Chicago.

Thursday, June 13

THIS SECTION WILL HOLD NO MEETING ON THIS DAY, BUT WILL JOIN WITH THE SECTION ON MISCELLANEOUS TOPICS

Friday, June 14—9 a. m.

Election of Officers

15. How Surgeons Can Help Win the War.
Franklin H. Martin, Chicago.

Joseph Rilus Eastman, Indianapolis.

17. Experience with Thirty-Five Cases of Gunshot Wounds of the Abdomen in 1917 at the Memphis General Hospital. Max Goltman, Memphis, Tenn.
Discussion to be opened by George L. Hays, Pittsbur

18. Avoidable Traumatic Abdomen.
John B. Deaver, Philadelphia.
Discussion to be opened by Thomas J. Watkins, Chicago.

19. Treatment of Incisional Ventral Hernia by the Transplantation of Fascia Lata (Lantern Demonstration).
Willard Bartlett, St. Louis.
Discussion to be opened by Arthur T. Mann, Minneapolis.

20. Short Circuiting Operations in Abdominal Surgery.
Alexius McGlannan, Baltimore.

21. Infantilism and Other Hypoplastic Conditions of the Uterus (Lantern Demonstration).
Emil Novak, Baltimore.
Discussion to be opened by William P. Graves, Boston.

Friday, June 14—2 p. m.

22. Paravertebral Anesthesia, with Report of One Hundred Cases. Nathaniel R. Mason and Frank C. W. Konrad, Boston.
Discussion to be opened by John Osborne Polak, Brooklyn.

23. Age of Menopause: Observations Based on Statistical Data of Eight Hundred Menopause Cases.
K. I. Sanes, Pittsburgh.
Discussion to be opened by Curtis S. Foster, Pittsburgh.

24. The Pathology of Hemorrhagic Myomas and Their Relation to Sarcoma (Lantern Demonstration).
Arthur E. Hertzler, Kansas City.
Discussion to be opened by Thomas S. Cullen, Baltimore.

25. The Radical Treatment of Cancer of the Cervix by Igni Extirpation (Lantern Demonstration).
Edward A. Weiss, Pittsburgh.
Discussion to be opened by Albert Goldspohn, Chicago.

26. The Conservation of Ovaries After Hysterectomy: With a New Technic of Extirpation of the Uterus.
George Gellhorn, St. Louis.
Discussion to be opened by Henry T. Byford, Chicago.

27. Plastic Operations in the Vagina and on the Pelvic Floor.
Stephen E. Tracy, Philadelphia.
Discussion to be opened by Horace G. Wetherill, Denver.

SECTION ON OPHTHALMOLOGY

MEETS IN GRAND BALL ROOM, HOTEL LA SALLE

OFFICERS OF SECTION

Chairman—Alexander Duane, New York.
Vice Chairman—F. Phinizy Calhoun, Atlanta, Ga.
Secretary—George S. Derby, Boston.
Acting Secretary—Edgar S. Thomson, New York.
Executive Committee—Edward C. Ellett, Memphis, Tenn.; Walter R. Parker, Detroit; William Zentmayer, Philadelphia.

(Stenographer—Dr. G. G. Taylor, Chicago)

Members are reminded that the meetings of the section will be called to order promptly on the hour scheduled for opening.

The formal reading of the papers will be omitted, as reprints of the papers on the program have already been delivered to members of the section.

Each essayist will be given ten minutes in which to summarize the points in his paper and introduce the discussion, and five minutes in which to close the discussion.

The member appointed to open the discussion of any paper will be allowed ten minutes. Subsequent speakers will be limited to five minutes.

The papers and all discussions will be printed and bound, forming the Transactions of the Section on Ophthalmology for 1917. Copies of the Transactions may be obtained at $1 each, if subscriptions are sent to The Journal of the American Medical Association, 535 North Dearborn Street, Chicago, by July 1, as only enough copies are printed to cover subscriptions received up to the time of going to press.

Members of the Section are requested to register in the section registration book at the entrance. The full name and complete postoffice address should be written plainly.

Wednesday, June 12—9 a. m.

1. Chairman's Address. Alexander Duane, New York.

2. Disciform Keratitis. John E. Weeks, New York.
Discussion to be opened by William Zentmayer, Philadelphia.

3. The Action of Miotic Drugs on Eyes, with Incomplete Sphincter Iritis. Robert J. Curdy, Kansas City, Mo.
Discussion to be opened by Frank C. Todd, Minneapolis.

4. Paralysis of the Sixth Cranial Nerve Associated with Otitis Media. John M. Wheeler, New York.
Discussion to be opened by Walter H. Snyder, Toledo, Ohio.

5. The Relation of Hereditary Defects of the Eye to Modern Genetics and Eugenics. Lucien Howe, Buffalo.
Discussion to be opened by Frank Allport, Chicago, and Harold H. Newman, Salisbury, N. C.

6. The Rational Etiology and Satisfactory Treatment of Dacryocystitis.
William R. Thompson, Fort Worth, Texas.
Discussion to be opened by Harry W. Woodruff, Joliet, Ill.

Wednesday, June 12—2 p. m.

EXHIBITION OF NEW INSTRUMENTS AND APPLIANCES

7. Some Aspects of Military Ophthalmic Surgery.
George E. de Schweinitz, Philadelphia.

8. Visual Standards of the U. S. Army.
William H. Wilder, Chicago.

9. Visual Standards of the U. S. Navy.
William E. Carson, Washington, D. C.

10. The Eyes of the Army. Allen Greenwood, Boston.
Discussion to be opened by Hiram Woods, Baltimore.

11. Maculocerebral Degeneration with Dementia.
Howard S. Clark, Minneapolis.
Discussion to be opened by F. Park Lewis, Buffalo.

Thursday, June 13

THIS SECTION WILL HOLD NO MEETING ON THIS DAY, BUT WILL JOIN WITH THE SECTION ON MISCELLANEOUS TOPICS

Friday, June 14—9 a. m.

Election of Officers

12. Pollakiuria or Excessive Frequency of Micturition as a Functional Disturbance Due to Eyestrain.
William W. Kahn, Detroit.
Discussion to be opened by Isaac Hartshorne, New York.

13. Astigmatism Against the Rule.
John Green and William F. Hardy, St. Louis.
Discussion to be opened by Walter B. Lancaster, Boston.

14. Common Changes in Regular Astigmatism and Their Causes. Edward Jackson, Denver.
Discussion to be opened by Arthur G. Bennett, Buffalo.

15. Focal Infections of the Eye from the Intestinal Tract.
James G. Dwyer, New York.
Discussion to be opened by Edgar S. Thomson, New York.

16. Alterations in the Visual Fields Associated with Pellagra.
F. Phinizy Calhoun, Atlanta, Ga.
Discussion to be opened by Edward V. L. Brown, Chicago.

17. A Study of the Histology and Pathology of the Superstructure of the Lid Occurring in Trachoma (Lantern Demonstration). Edward H. Cary, Dallas, Texas.
Discussion to be opened by Meyer Wiener, St. Louis.

Friday, June 14—2 p. m.

18. The Etiology of Phlyctenular Ophthalmia.
Hunter H. Turner, Pittsburgh.
Discussion to be opened by Edward B. Heckel, Pittsburgh.

19. Postciliary Scleral Trephining for Acute Glaucoma.
Arthur E. Ewing, St. Louis.
Discussion to be opened by Edward C. Ellett, Memphis, Tenn.

20. The Treatment of Blood Cysts of the Orbit.
HAROLD GIFFORD, Omaha.
Discussion to be opened by ALBERT E. BULSON, JR., Fort Wayne, Ind.

21. The Management of Certain Intractable Lid Conditions.
MELVILLE BLACK, Denver.
Discussion to be opened by GILES C. SAVAGE, Nashville, Tenn.

22. An Operation for Cataract. Especially Adapted to Cases of Intractable Sepsis of the Conjunctiva or the Lacrimal Sac. ARTHUR E. PRINCE, Springfield, Ill.
Discussion to be opened by JOHN D. PIFER, Joplin, Mo.

23. A Method of Acquiring Cataract Technic Leading to the Smith-Indian Intracapsular.
WILLIAM A. FISHER and H. D. THORNBURG, Chicago.
Discussion to be opened by LOUIS D. GREEN, San Francisco.

SECTION ON LARYNGOLOGY, OTOLOGY AND RHINOLOGY

MEETS IN RED ROOM, HOTEL LA SALLE

OFFICERS OF SECTION

Chairman—GREENFIELD SLUDER, St. Louis.
Vice Chairman—PHILIP D. KERRISON, New York.
Secretary—L. W. DEAN, Iowa City, Iowa.
Executive Committee—NORVAL H. PIERCE, Chicago; HILL HASTINGS, Los Angeles; FRANCIS P. EMERSON, Boston.
(Stenographer—Miss F. E. DILLAN, Indianapolis)

Wednesday, June 12—9 a. m.

1. Chairman's Address: The Specialist's Relations to the American Medical Association.
GREENFIELD SLUDER, St. Louis.
2. Acromegaly of the Larynx.
CHEVALIER JACKSON, Philadelphia.
3. Certain Traumatic Lesions of the Esophagus.
THOMAS HUBBARD, Toledo, Ohio.
4. Indurative Headaches. HUGH T. PATRICK, Chicago.
5. Ocular Headaches. JOSEPH W. CHARLES, St. Louis.

Wednesday, June 12—2 p. m.

EXHIBITION OF NEW INSTRUMENTS AND APPLIANCES

6. Otolaryngology in the Army Medical Service.
NORVAL H. PIERCE, Chicago.
7. Results of Concussion of High Explosive Shells on the Ear. J. GORDON WILSON, Chicago.
8. Endoscopic Diagnosis and Treatment.
EDGAR M. HOLMES, Boston.
9. Bilateral Ankylosis of the Crico-Arytenoid Joint, with Report of a Case. THOMAS J. HARRIS, New York.
10. Amputation of the Epiglottis in Cases of Laryngeal Tuberculosis. THOMAS E. CARMODY, Denver.

Thursday, June 13

THIS SECTION WILL HOLD NO MEETING ON THIS DAY, BUT WILL JOIN WITH THE SECTION ON MISCELLANEOUS TOPICS

Friday, June 14—9 a. m.

Election of Officers

11. Anatomy of the Nasal Accessory Sinuses in Infancy and Childhood. WARREN B. DAVIS, Philadelphia.

(Stenographer—Mr. J. M. Carney, Milwaukee)

Wednesday, June 12—9 a. m.

1. Chairman's Address: The Teaching of Pharmacology.
Arthur D. Hirschfelder, Minneapolis.

SYMPOSIUM ON ACTIVITIES BEARING ON THE WAR

2. Pharmacology in the War.
Torald Sollmann, Cleveland.

3. The Problem of Synthetic Drugs.
Julius Stieglitz, Chicago.

4. Industrial Hazards in War Time.
Alice Hamilton, Chicago.

5. The Chemical Control of Lice.
William Moore, St. Paul.

Wednesday, June 12—2 p. m.

JOINT MEETING WITH THE SECTION ON PATHOLOGY AND PHYSIOLOGY

SYMPOSIUM ON DISEASES DUE TO DEFICIENCIES IN NUTRITION

6. The "Vitamin" Hypothesis and the Diseases Referable to Faulty Diet. E. V. McCullum, Baltimore.

7. The Rôle of Antiscorbutics in Our Dietary.
Alfred F. Hess, New York.

8. Diet and Pellagra.
Joseph Goldberger, G. A. Wheeler and Edgar Sydenstricker, Washington, D. C.

9. Diet of the U. S. Army Soldier.
John R. Murlin, Washington, D. C.

10. Civilian War Rations.
Paul Roth, Battle Creek, Mich.

Thursday, June 13

THIS SECTION WILL HOLD NO MEETING ON THIS DAY, BUT WILL JOIN WITH THE SECTION ON MISCELLANEOUS TOPICS

Friday, June 14—9 a. m.

Election of Officers

11. On the Pharmacologic and Therapeutic Properties of Some Benzyl Esters. David I. Macht, Baltimore.

12. The Significance of Sounds Heard During the Auditory Measurement of Blood Pressure.
Clyde Brooks, Pittsburgh, and Albert M. Bleile, Columbus, Ohio.

13. The Chemical Groups in the Active Constituent of the Thyroid Which Are Responsible for Its Physiologic Activity. E. C. Kendall, Rochester, Minn.

14. Studies in a Case of Acute Bichlorid of Mercury Poisoning, Treated by the Newer Methods and Followed by Recovery. Jacob Rosenbloom, Pittsburgh.

15. A Study of the Delayed Kidney Injury Induced by Bichlorid of Mercury.
William DeB. MacNider, Chapel Hill, N. C.

Friday, June 14—2 p. m.

16. The Relationship of the Strength of the Effective Stimulus and the Irritability of the Respiratory Center.
Roy G. Pearce, Cleveland.

17. The Therapeutic Indications for the Inhalation of Oxygen.
Charles F. Hoover, Cleveland.

18. Clinical Studies of a Series of Cases Presenting the Phenomena of Cholesteremia.
John R. Williams, Rochester, N. Y.

19. Studies on the Valuation of Digitalis.
E. L. Newcomb, Minneapolis.

20. Pharmacologic Studies on Arnica.
E. D. Brown, A. M. Smith and A. C. Johnson, Minneapolis.

SECTION ON PATHOLOGY AND PHYSIOLOGY

MEETS IN THE BALL ROOM, AUDITORIUM HOTEL

OFFICERS OF SECTION

Chairman—Louis B. Wilson, Rochester, Minn.
Vice Chairman—Francis Carter Wood, New York.
Secretary—Isabella C. Herb, Chicago.
Executive Committee—A. J. Carlson, Chicago; F. P. Gay, Berkeley, Calif.; James Ewing, New York.
(Stenographer—Dr. Anna C. Landman, Chicago)

Wednesday, June 12—9 a. m.

1. Chairman's Address: Necropsies in American Hospitals.
Louis B. Wilson, Rochester, Minn.

2. The Function of Fats in Immune Reactions.
Carl C. Warden, Ann Arbor, Mich.

3. A New Method of Making the Gonorrheal Complement Fixation Test. R. B. H. Gradwohl, St. Louis.

4. A Further Consideration of Complement Fixation in Tuberculosis. V. H. Moon, Indianapolis.

5. Industrial Fatigue and the War.
Frederic S. Lee, New York.

Wednesday, June 12—2 p. m.

JOINT MEETING WITH THE SECTION ON PHARMACOLOGY AND THERAPEUTICS

SYMPOSIUM ON DISEASES DUE TO DEFICIENCIES IN NUTRITION

6. The "Vitamin" Hypothesis and the Diseases Referable to Faulty Diet. E. V. McCollum, Baltimore.

7. The Rôle of Antiscorbutics in Our Dietary.
Alfred F. Hess, New York.

8. Diet and Pellagra.
Joseph Goldberger, G. A. Wheeler and Edgar Sydenstricker, Washington, D. C.

9. Diet of the U. S. Army Soldier.
John R. Murlin, Washington, D. C.

10. Civilian War Rations. Paul Roth, Battle Creek, Mich.

Thursday, June 13

THIS SECTION WILL HOLD NO MEETING ON THIS DAY, BUT WILL JOIN WITH THE SECTION ON MISCELLANEOUS TOPICS

Friday, June 14—9 a. m.

Election of Officers

11. Some Observations on the Pathology of the Urine in Arteriosclerotic Kidney.
B. G. R. Williams, Paris, Ill.

12. A Further Experimental Study on Surgical Shock.
Frank C. Mann, Rochester, Minn.

13. The Resistance of the Streptococcus Viridans to Germicidal Agents. Henry Albert, Iowa City, Iowa.

14. The Relationship of Hodgkin's Disease to Lymphosarcoma. Michael G. Wohl, Omaha.

SECTION ON STOMATOLOGY

MEETS IN GREEN ROOM, CONGRESS HOTEL

OFFICERS OF SECTION

Chairman—Frederick B. Noyes, Chicago.
Vice Chairman—Henry S. Dunning, New York.
Secretary—Eugene S. Talbot, Chicago.
Executive Committee—William C. Fisher, New York; Frederick B. Moorehead, Chicago; Arthur D. Black, Chicago.

(Stenographer—Miss Margaret I. Maloney, Chicago)

Wednesday, June 12—9 a. m.

1. Chairman's Address: Dental Lymphatic Vessels.
Frederick B. Noyes, Chicago.

2. An Analysis of Two Hundred Cases of Malignant Disease in the Oral Cavity Treated by Electrothermic Methods, or in Combination with Operative Surgery, Roentgen Rays or Radium.
William L. Clark, Philadelphia.

3. Treatment of Epithelioma of the Jaws and Cheeks, with Heat and Radium.
Gordon B. New, Rochester, Minn.
Discussion to be opened by Albert J. Ochsner, Chicago.

Wednesday, June 12—2 p. m.

4. The Lipoids of Tumors of the Dental System.
Kaethe W. Dewey, Chicago.

5. The Genesis of Nasmyth's Membrane, the Epithelial Débris in the Peridental Membrane and the Granular Layer of Tomes. Eugene S. Talbot, Chicago.

6. Additional Roentgenographic Studies of Infections of the Maxillary Bones. Arthur D. Black, Chicago.

Thursday, June 13

THIS SECTION WILL HOLD NO MEETING ON THIS DAY, BUT WILL JOIN WITH THE SECTION ON MISCELLANEOUS TOPICS

Friday, June 14—9 a. m.

Election of Officers

7. Microscopic Studies of Diseased Peridental Tissues (Lantern Demonstration).
Edward H. Hatton, Chicago.

8. Absorption of the Roots of Teeth (Lantern Demonstration). Herbert A. Potts, Chicago.

9. Neuralgia Dentalis. Kurt H. Thoma, Boston.

Friday, June 14—2 p. m.

10. Longitudinal and Transverse. Sectional Views of the Accessory Sinuses of the Human Cranium, Cut Parallel and at Right Angles to the Nasal Septum (Lantern Demonstration).
George Edward Fell, Chicago.

11. A New Surgical Procedure for Operating in Cases of Suppurative Gingivitis, with Alveolar Involvement (Lantern Demonstration).
Arthur Zentler, New York.

12. Fractures and Dislocations of the Jaws.
Chalmers J. Lyons, Ann Arbor, Mich.

13. Fractures of the Bones of the Face, with Complication.
Vida Latham, Chicago.

SECTION ON NERVOUS AND MENTAL DISEASES

MEETS IN BALL ROOM, BLACKSTONE HOTEL

OFFICERS OF SECTION

Chairman—C. Eugene Riggs, St. Paul.
Vice Chairman—Charles W. Hitchcock, Detroit.
Executive Committee—William W. Graves, St. Louis; Francis X. Dercum, Philadelphia; Bernard Sachs, New York.

(Stenographer—Miss Adelaide Folsom, Ripon, Wis.)

Wednesday, June 12—9 a. m.

1. Chairman's Address: Some Further Considerations Concerning the Treatment of Neurosyphilis.
C. Eugene Riggs, St. Paul.

2. Conjugal Syphilis of the Nervous System.
Alfred Gordon, Philadelphia.

3. The Interpretation of Negative Laboratory Findings in Syphilis, with Special Reference to Treatment.
Albert E. Sterne, Indianapolis.

4. Cerebral Edema Due to Pressure.
William A. Jones, Minneapolis.

5. Motor Disturbances Resulting from Lesions of the Corpus Striatum: A Discussion of the Striospinal System and Its Relation to Motility.
J. Ramsay Hunt, New York.

6. Carbon Monoxid Poisoning, with Report of a Case: Its Nervous and Mental Symptoms.
Charles W. Hitchcock, Detroit.

Wednesday, June 12—2 p. m.

7. Nervous and Mental Symptoms in Exophthalmic Goiter.
Lewellys F. Barker, Baltimore.

8. Medical Treatment of Exophthalmic Goiter, Especially the Use of the Extract of Corpus Luteum.
Herman H. Hoppe, Cincinnati.

9. Pituitary Disturbance in Relation to the Psychoses of Adolescence. Beverly R. Tucker, Richmond, Va.

10. Pineal Gland Neoplasms, with Report of a Case Studied Clinically and Pathologically (Lantern Demonstration).
Andrew L. Skoog, Kansas City, Mo.

11. The Visceral Symptomatology of Nervous Diseases.
Francis X. Dercum, Philadelphia.

12. Prognosis in Traumatic Neurosis.
Walter F. Schaller, San Francisco.

Thursday, June 13—9 a. m.

13. Neuropsychiatry and the Mobilization.
Representative of the Office of the Surgeon-General, U. S. Army.

14. Neurologic Reconstruction Work in the Army.
Richard H. Hutchings, Washington, D. C.

15. War Neuroses as a Community Problem.
Frankwood E. Williams, New York.

16. The Intensive Teaching of Neurology to Members of the Medical Reserve Corps.
Theodore H. Weisenberg, Philadelphia.

17. The Neuropsychiatric Personnel: The Character and Make-Up of the Members of the Neuropsychiatric Division of the Medical Reserve Corps.
Walter Timme, New York.

18. The Interpretation of Shell Shock.
B. Sachs, New York.

Thursday, June 13—2 p. m.

Election of Officers

19. The Results of Studying the Psychosis from the Standpoint of the Clinical and Pathologic Laboratory.
Henry A. Cotton, Trenton, N. J.

20. The Personal Equation in Psychiatry.
Lawrence B. Pilsbury, Lincoln, Neb.

21. The Medical Practitioner and Mental Hygiene.
H. Douglas Singer, Kankakee, Ill.

22. Treatment of Toxic and Exhaustion Psychoses.
Frank P. Norbury, Jacksonville, Ill.

23. Dementia Praecox: Its Diagnosis, Prognosis and Treatment. Charles R. Ball, St. Paul.

24. A Psychiatric Contribution to the Problem of Prison Reform. Herman M. Adler, Chicago.

Friday, June 14—9 a. m.

25. The Cerebellar Gait: A Pedographic Study.
I. Leon Meyers, Chicago.

26. Some Suggestions for More Accurate Mental Therapy in Epilepsy. L. Pierce Clark, New York.

27. Radiculitis: Its Diagnosis and Interpretation.
Edward E. Mayer, Pittsburgh.

28. Posterior Column Lesions Nonspecific.
Otto G. Freyermuth, San Francisco.

29. Early Manifestations of Nervous and Mental Instability
E. Bosworth McCready, Pittsburgh.

30. Insanity versus Mental Disease: Duty of the General Practitioner in Psychiatric Diagnosis.
Elmer E. Southard, Boston.

SECTION ON DERMATOLOGY

MEETS IN ENGLISH ROOM, BLACKSTONE HOTEL

OFFICERS OF SECTION

Chairman—Henry H. Hazen, Washington, D. C.
Vice Chairman—Ernest Dwight Chipman, San Francisco.
Secretary—Walter J. Heimann, New York.
Executive Committee—Howard Fox, New York; Howard Morrow, San Francisco; Henry R. Varney, Detroit.
(Stenographer—Mrs. Irene Hilton Snyder, Chicago)

Wednesday, June 12—9 a. m.

1. Chairman's Address: The Duties of the Dermatologist. Henry H. Hazen, Washington, D. C.

SYMPOSIUM ON SKIN TUBERCULOSIS

2. Cutaneous Tuberculosis: A Survey. Sigmund S. Pollitzer, New York.
3. Miliary Tuberculosis of the Skin, Lichen Scrofulosum and Papulonecrotic Tuberculosis. Fred Wise, New York.
4. Sarcoids and Erythema Induratum of Bazin. Samuel E. Sweitzer and Henry E. Michelsen, Minneapolis.
5. Dermatoses Possibly Related to Tuberculosis. Max Scheer, New York.
6. The Too Intensive Salvarsan Treatment of Syphilis. Meyer L. Heidingsfeld, Cincinnati.

Wednesday, June 12—2 p. m.

SYMPOSIUM ON SYPHILIS IN ITS ECONOMIC ASPECTS

7. Experimental Therapy in Syphilis Wade H. Brown and Louise Pearce, New York.
8. The Handling of the Venereal Disease Problem in the Army. William A. Pusey, Chicago.
9. The Value of Early Diagnosis and Immediate Treatment in Preventing Neurosyphilis: Its Economic Aspects. John A. Fordyce, New York.
10. Syphilis and Venereal Diseases as a Public Health Problem. Harry G. Irvine, Minneapolis.

Thursday, June 13

THIS SECTION WILL HOLD NO MEETING ON THIS DAY, BUT WILL JOIN WITH THE SECTION ON MISCELLANEOUS TOPICS

Friday, June 14—9 a. m.

Election of Officers

SYMPOSIUM ON BULLOUS DERMATOSES

11. The Etiology of Dermatitis Herpetiformis and Its Relation to Other Bullous Diseases, Especially Erythema Multiforme and Pemphigus. Milton B. Hartzell, Philadelphia.
12. Pemphigus: A Clinical Study. Hermann Goldenberg and Walter J. Heimann, New York.
13. The Significance of Certain Bullous Eruptions. Martin F. Engman and Richard S. Weiss, St. Louis.
14. Toxic and Bullous Drug Eruptions and the Bullous Erythemas. David Lieberthal, Chicago.
15. Unusual Forms of Epitheliomas of the Skin. Lloyd W. Ketron, Baltimore.

Friday, June 14—2 p. m.

16. The Rôle of the Vegetative Nervous System in Certain Diseases of the Skin. Edward H. Reede, Washington. D. C.
17. Further Observations Concerning Dermatoses Attributed to Focal Infections. Michael L. Ravitch and Sol A. Steinberg, Louisville, Ky.
18. Retention of Cysts of the Mucous Membrane. Richard L. Sutton, Kansas City, Mo., and Frank E. Simpson, Chicago.
19. Adenoma Sebaceum: Report of Five Cases in One Family. Jesse B. Shelmire and James H. Black, Dallas, Texas.
20. Dermatitis Lycopersicum Esculentum. Everett S. Lain, Oklahoma City, Okla.
21. A Case of Sporotirchosis. Joseph S. Eisenstaedt, Chicago.
22. The Etiology of Lichen Planus. Ernest D. Chipman, San Francisco.

SECTION ON PREVENTIVE MEDICINE AND PUBLIC HEALTH

MEETS IN THE BANQUET HALL, AUDITORIUM HOTEL

OFFICERS OF SECTION

Chairman—W. S. Rankin, Raleigh, N. C.
Vice Chairman—Haven Emerson, New York.
Secretary—Don B. Lowe, Akron, Ohio.
Executive [illegible] Jones, Baltimore; William C. Ruck[illegible]; Otto P. Geier, Cincinnati.
(Stenographer—Mr. Frederick H. Gurtler, Chicago)

Wednesday, June 12—9 a. m.

SYMPOSIUM ON RURAL SANITATION

1. Coordinate Responsibility of Nation, State and County in Rural Sanitation. Watson S. Rankin, Raleigh, N. C.
2. State Responsibility and Aims in County Health Work. John N. Hurty, Indianapolis.
3. The Unit Development of County Health Work. Waller S. Leathers, University, Miss.

Wednesday, June 12—2 p. m.

JOINT MEETING WITH THE SECTION ON ORTHOPEDIC SURGERY

4. Military and Industrial Orthopedic Surgery. Albert H. Freiberg, Cincinnati.
5. Orthopedic Surgery in Reclaiming the Crippled Soldier. Elliott G. Brackett, Washington, D. C.
6. The Conservation of Man Power in the Industries. Charles G. Farnum, Peoria, Ill.
7. Conserving Industrial Man Power. Clarence D. Selby, Toledo, Ohio.
8. Responsibility of the Industrial Board and the Influence of the Medical Examiner. Charles S. Andrus, Chicago.
9. Reconstruction Work in Industrial and Military Life. Francis Patterson, Harrisburg, Pa.

Thursday, June 13, 9 a. m.

Election of Officers

SYMPOSIUM ON MUNICIPAL HEALTH ADMINISTRATION

10. Municipal Health Administration: General Considerations. Ernest C. Levy, New York.
11. Health Administration in Cities of Less than Twenty Thousand Population. Donald B. Armstrong, Framingham, Mass.
12. Health Administration in Cities with a Population Between 20,000 and 100,000. Jacob Furstman, La Crosse, Wis.
13. Health Administration in Cities with a Population Between 100,000 and 500,000. John H. Landis, Cincinnati.

Friday, June 14—9 a. m.

SYMPOSIUM ON MILITARY HYGIENE AND PREVENTIVE MEDICINE

14. Prevention of Pneumonia. Rufus I. Cole, New York.
15. Control of Meningitis. Simon Flexner, New York.
16. Measles. Edward L. Munson, Washington, D. C.
17. Mumps. Martha Wollstein, New York.
18. Venereal Disease Control in the Army. William F. Snow, New York, and Wilbur A. Sawyer, Berkeley, Calif.

SECTION ON GENITO-URINARY DISEASES

MEETS IN SMOKING ROOM, AUDITORIUM THEATER

OFFICERS OF SECTION

Chairman—Edward L. Keyes, Jr., New York.
Vice Chairman—Martin Krotoszyner,* San Francisco.
Secretary—William F. Braasch, Rochester, Minn.
Executive Committee—Granville MacGowan, Los Angeles; Louis E. Schmidt, Chicago; Hugh Cabot, Boston.
(Stenographer—Mr. Douglas A. Brown, Cincinnati)

Wednesday, June 12—9 a. m.

1. Anatomic and Pathologic Study of the Posterior Urethra (Lantern Demonstration). E. Otis Smith, Cincinnati.

---

* Deceased.

2. The Human Seminal Vesicles at Birth, with Observations on Their Fetal Development (Lantern Demonstration).
Ernest M. Watson, Buffalo.
Discussion on the foregoing two papers to be opened by Oswald S. Lowsley, New York.

3. Why Trained Urologists Should be Employed to Treat Disease Conditions of the Posterior Urethra and the Bladder Neck (Lantern Demonstration).
Granville MacGowan, Los Angeles.
Discussion to be opened by L. Buerger, New York.

4. Venereal Diseases Incident to War Times.
William W. Townsend, Rutland, Vt.

5. Venereal Disease in the Thirty-Ninth Division.
Loyd Thompson, Hot Springs, Ark., and Jacob R. Bolasny, Detroit.

Wednesday, June 12, 2 p. m.

6. "Trench Nephritis." Reginald Fitz, Boston.

7. Renal Complications of Pregnancy from the Standpoint of the Neurologist (Lantern Demonstration).
Henry G. Bugbee, New York.
Discussion to be opened by Herman L. Kretschmer, Chicago, and John R. Caulk, St. Louis.

8. Experimental Hydronephrosis. Restoration of Function and Anatomic Repair After Relief of Obstruction (Lantern Demonstration).
Frank Hinman, San Francisco.
Discussion to be opened by James D. Barney, Boston.

9. Changes in the Kidney and Ureter Resulting from Renal Implantation of the Latter Into the Kidney.
Anders Peterson, Rochester, Minn.
Discussion to be opened by H. D. Furniss, New York.

10. Acquired Stricture of the Lower End of the Ureter (Lantern Demonstration). Robert H. Herbst, Chicago.
Discussion to be opened by V. D. Lespinasse, Chicago.

11. Simple Ulcer of the Bladder.
Arthur B. Cecil, Los Angeles.
Discussion to be opened by William F. Braasch, Rochester, Minn.

Thursday, June 13

THIS SECTION WILL HOLD NO MEETING ON THIS DAY, BUT WILL JOIN WITH THE SECTION ON MISCELLANEOUS TOPICS

Friday, June 14—9 a. m.

Election of Officers

12. New Instruments In Operative Cystoscopy.
Bransford Lewis, St. Louis.

13. Pathology and Improved Method of Operating For Obstructive Lesions of the Internal Vesical Sphincter (Lantern Demonstration).
Leo Buerger, New York.
Discussion to be opened by Oswald S. Lowsley, New York.

14. Surgery and Surgical Pathology of the Human Prostate Gland. Oswald S. Lowsley, New York.
Discussion to be opened by H. L. Kretschmer, Chicago.

15. The Silent Prostate. James A. Gardner, Buffalo.
Discussion to be opened by H. L. Kretschmer, Chicago.

16. Radical and Palliative Operative Procedure for Carcinoma of the Prostate (Lantern Demonstration).
John T. Geraghty, Baltimore.
Discussion to be opened by Granville MacGowan, Los Angeles, and Benjamin S. Barringer, New York.

17. Some Cases of Retention of Urine Associated With Defects of the Sacrum; Probably Spina Bifida Occulta.
Artur L. Chute, Boston.

Friday, June 14—2 p. m.

18. Treatment of Genital Tuberculosis in the Male (Lantern Demonstration). William C. Quinby, Boston.
Discussion to be opened by John T. Geraghty, Baltimore, and John H. Cunningham, Jr., Boston.

19. Colon Bacillus Infection of the Urinary Tract.
J. Dellinger Barney, Boston.
Discussion to be opened by H. L. Kretschmer, Chicago.

20. The Significance of Bacteriuria.
Louis E. Schmidt, Chicago.
Discussion to be opened by Granville MacGowan, Los Angeles.

21. The Diagnostic and Prognostic Value of Blood Urea in Urology. Albert E. Goldstein, Baltimore.
Discussion to be opened by R. B. H. Gradwohl, St. Louis, and Henry J. Scherck, St. Louis.

SECTION ON ORTHOPEDIC SURGERY

MEETS IN ELIZABETHAN ROOM, CONGRESS HOTEL

OFFICERS OF SECTION

Chairman—Albert H. Freiberg, Cincinnati.
Vice Chairman—Fred J. Fassett, Seattle.
Secretary—Henry B. Thomas, Chicago.
Executive Committee—Nathaniel Allison, St. Louis; Russell A. Hibbs, New York; E. W. Ryerson, Chicago.
(Stenographer—Miss Lulu Gay, Philadelphia)

Wednesday, June 12—9 a. m.

1. Efficient Support for Sacro-Iliac Relaxation.
W. Barnett Owen, Louisville.
Discussion to be opened by Fred J. Gaenslen, Milwaukee; Charles A. Parker, Chicago, and James W. Sever, Boston.

2. Tendon Operation Technic. Leo Mayer, New York.
Discussion to be opened by Robert W. Lovett, Boston; Mark H. Rogers, Boston, and Samuel Kleinberg, New York.

3. Loose Bodies in the Elbow Joint.
Melvin S. Henderson, Rochester, Minn.
Discussion to be opened by Willis C. Campbell, Memphis; E. W. Ryerson, Chicago, and Russell A. Hibbs, New York.

4. Orthopedic Operations on the Hand (Lantern Demonstration). Arthur Steindler, Iowa City, Iowa.
Discussion to be opened by John L. Porter and Allen B. Kanavel, Chicago.

5. Cerebral Spastic Paraplegia.
Walter G. Stern and M. E. Blahd, Cleveland.
Discussion to be opened by William Sharpe, New York, and Charles H. Frazier, Philadelphia.

Wednesday, June 12—2 p. m.

JOINT MEETING WITH THE SECTION ON PREVENTIVE MEDICINE AND PUBLIC HEALTH

6. Chairman's Address: Military and Industrial Orthopedic Surgery. Albert H. Freiberg, Cincinnati.

7. Orthopedic Surgery in Reclaiming the Crippled Soldier.
Elliott G. Brackett, Washington, D. C.
Discussion to be opened by John Ridlon, Chicago; Jefferson D. Griffith, Kansas City, Mo.; James T. Rugh, Philadelphia, and Emil S. Geist, Minneapolis.

8. The Conservation of Man Power in the Industries.
Charles G. Farnum, Peoria, Ill.

9. Conserving Industrial Man Power.
Clarence D. Selby, Toledo, Ohio.

10. Responsibility of the Industrial Board and the Influence of the Medical Examiner.
Charles S. Andrus, Chicago.

11. Reconstruction Work in Industrial and Military Life.
Francis Patterson, Harrisburg, Pa.
Discussion to be opened by Harry E. Mock, Washington, D. C., and Charles G. Farnum, Peoria, Ill.

Thursday, June 13

THIS SECTION WILL HOLD NO MEETING ON THIS DAY, BUT WILL JOIN WITH THE SECTION ON MISCELLANEOUS TOPICS

Friday, June 14—9 a. m.

Election of Officers

12. Disinfection of the Knee Joint.
Robert B. Cofield, Cincinnati.
Discussion to be opened by F. J. Cotton, Boston, and Walter G. Stern, Cleveland.

13. *Final Report of Operations for Pott's Disease.*
Russell A. Hibbs, New York.
Discussion to be opened by Charles M. Jacobs, Chicago.

14. Problem of the Artificial Arm.
David Silver, Pittsburgh.

15. The Determining of Permanent Disability in Foot Injuries.
Paul B. Magnuson, Washington, D. C.
Discussion to be opened by John R. Ridlon, Chicago.

16. Orthopedic Practice in Army Cantonments.

17. Isolated Disease of the Scaphoid.
Charles R. McClure, Portland, Ore.

18. Illustrations and Demonstration of Bone-Holding Forceps (Lantern Demonstration).
Robert Emmett Farr, Minneapolis.
Discussion to be opened by Emil S. Geist, and Archa E. Wilcox, Minneapolis.

Friday, June 14—2 p. m.

19. Infantile Paralysis. Robert W. Lovett, Boston.
Discussion to be opened by George Draper, New York.

20. A Further Report of an Operation for Stabilizing the Foot and Ankle in Poliomyelitis.
Frank E. Pecham, Providence, R. I.

21. *Poliomyelitis:* Better Results Now Demanded and Obtained by Continuous Orthopedic Treatment from the Onset of the Disease. Charles Ogilvy, New York.
Discussion to be opened by Royal Whitman, New York, Henry W. Frauenthal, New York, and Wallace Blanchard, Chicago.

22. A Study of the Infantile Paralysis Problem.
Clarence W. East, Springfield, Ill.
Discussion to be opened by John D. Trawick, Louisville, Ky., and Robert O. Ritter, Chicago.

23. Reconstruction of the Hip Joint in Paralytic Luxation.
Ellis W. Jones, Los Angeles.

24. Plastic Surgery of the Hip and Its Approaches.
Frederick H. Albee, New York.
Discussion to be opened by Elliott G. Brackett, Washington, D. C., and Philip H. Kreuscher, Chicago.

SECTION ON GASTRO-ENTEROLOGY AND PROCTOLOGY

MEETS IN LADIES' PARLOR, AUDITORIUM THEATER

OFFICERS OF SECTION

Chairman—Anthony Bassler, New York.
Vice Chairman—Alois B. Graham, Indianapolis.
Secretary—Horace W. Soper, St. Louis.
Executive Committee—William Van V. Hayes, New York; Charles G. Stockton, Buffalo; Dwight H. Murray, Syracuse.
(Stenographer—Mr. H. C. McDermott, Milwaukee, Wis.)

Wednesday, June 12—9 a. m.

1. Chairman's Address. Anthony Bassler, New York.

2. A Simplified Method of Aspirating Gastric Contents in Hypersensitive Patients. Charles D. Aaron, Detroit.
Discussion to be opened by G. W. McCaskey, Fort Wayne, Ind.; John P. Sawyer, Cleveland, and Joseph Merzback, Brooklyn.

3. The Possibilities of Fractional Gastric Analysis.
Martin E. Rehfuss, Philadelphia.
Discussion to be opened by Charles P. Horner, Chicago; Arthur L. Holland, New York; Allen A. Jones, Buffalo, and A. F. R. Andresen, Brooklyn.

4. The Importance of Detailed Examinations of Drafted Men With Regard to Their Ability to be Soldiers.
Max Einhorn, New York.
Discussion to be opened by Seale Harris, Birmingham, Ala.; Charles G. Stockton, Buffalo, and Harlow Brooks, New York.

5. A Résumé of Eight Years' Original Research Work in the Etiology and Treatment of Pruritus Ani.
Dwight Henderson Murray, Syracuse, N. Y.
Discussion to be opened by J. M. Frick, Toledo; Charles H. Chetwood, New York; Granville S. Hanes, Louisville, Ky., and W. H. Kiger, Los Angeles.

6. The Comparative Value of Crude Ipecac and Its Alkaloids in the Treatment of Amebiasis.
Sidney K. Simon, New Orleans.
Discussion to be opened by George Dock, St. Louis; Frank C. Yeomans, New York; J. C. Johnson, Atlanta, Ga., and T. C. Martin, Washington, D. C.

Wednesday, June 12—2 p. m.

Election of Officers

7. *Pericholecystitic Adhesions:* Their Importance and Clinical Recognition. Frank Smithies, Chicago.
Discussion to be opened by John B. Deaver, Philadelphia; Franklin W. White, Boston; Max Einhorn, New York, and Dudley Roberts, Brooklyn.

8. The Probable Endocrinic Origin of Peptic Ulcer (Lantern Demonstration). G. A. Friedman, New York.
Discussion to be opened by Frank C. Mann, Rochester, Minn.; Jacob Kaufman, New York, and Watson W. Eldridge, Jr., New York.

9. The Influence of Diet on the Symptoms and Course of Pellagra. George C. Mizell, Atlanta, Ga.
Discussion to be opened by Julius Friedenwald, Baltimore; Sidney K. Simon, New Orleans; Frank W. Foxworthy, Indianapolis, and Joseph E. Knighton, Shreveport, La.

10. The Trichomonas Hominis, An Occasional Cause of Intestinal Disturbance.
Emmett H. Terrell, Richmond, Va.
Discussion to be opened by John L. Jelks, Memphis, Tenn.; Granville S. Hanes, Louisville, Ky.; George M. Niles, Atlanta, Ga., and Marvin H. Smith, Jacksonville, Fla.

11. The End-Results of Operations for Cancer of the Rectum, With Suggestions for Improving Them (Lantern Demonstration). J. Rawson Pennington, Chicago.
Discussion to be opened by Collier F. Martin, Philadelphia; William H. Stauffer, St. Louis; John M. Frankenberger, Kansas City, Mo., and James A. Duncan, Toledo, Ohio.

Thursday, June 13

THIS SECTION WILL HOLD NO MEETING ON THIS DAY, BUT WILL JOIN WITH THE SECTION ON MISCELLANEOUS TOPICS

Friday, June 14—2 p. m.

12. The Origin of Pericolic Adhesions With Special Reference to Elbow Deformity of the Colon.
Jerome M. Lynch, New York.
Discussion to be opened by Jabez N. Jackson, Kansas City, Mo.; James C. Bloodgood, Baltimore; Charles J. Drueck, Chicago, and J. Coles Brick, Philadelphia.

13. The Importance of Complete Roentgen Study of the Gastro-Intestinal Tract and Gallbladder in All Obscure Abdominal Cases (Lantern Demonstration).
George E. Pfahler, Philadelphia.
Discussion to be opened by Bertram W. Sippy, Chicago; Walter Hamburger, Chicago; Leo H. Neuman, Albany, N. Y., and Armistead C. Crump, New York.

14. The Apparent Relation Between Intestinal Stasis and Some Cases of Epilepsy.
William Gerry Morgan, Washington, D. C.
Discussion to be opened by J. Ramsay Hunt, New York; Martin E. Rehfuss, Philadelphia; Curran Pope, Louisville, Ky., and James F. Munson, Sonyea, N. Y.

15. Reflex Symptoms from Anal, Rectal and Sigmoidal Lesions Alfred J. Zobel, San Francisco.
Discussion to be opened by T. Chittenden Hill, Boston; George B. Evans, Dayton, O.; Donly C. Hawley, Burlington, Vt., and Louis H. Adler, Philadelphia.

16. The Subnormal Colon.
William M. Beach, Pittsburgh.
Discussion to be opened by Ralph W. Jackson, Fall River, Mass.; Arthur Hebb, Baltimore; James A. MacMillan, Detroit, and James A. McVeigh, Detroit.

17. Intestinal Obstruction: Continued Studies from Surgical Research Laboratory, New York University.
Harry B. Eisberg and John W. Draper, New York.

List of Exhibitors

	Exhibit Space No.
Abbott Laboratories, The, Chicago	102

Educational Value of the Commercial Exhibit

Following the trend of progress, purveyors of accessories to medical and surgical practice are watchful of the latest and most practical developments suggested to them by medical science. It is with a view of demonstrating to the visiting physician the developments of the past year, as represented in improved apparatus, instruments, pharmaceuticals, new books, etc., that over 100 firms will congregate this year in the Exhibit Hall, banquet floor, Hotel Sherman, under the auspices of the A. M. A.

The progressive physician cannot fail to appreciate the increasing scientific and educational importance of these exhibits. They bring before him just those innovations which, as a scientific and progressive member of the profession, he desires to know with a view to adapting them to his own work. After all, success in practice consists not only of a thorough and practical knowledge of medicine and surgery, but of having equipment that enables one to apply this knowledge to the best advantage. The war, naturally, has placed increased pressure upon the necessity for better methods of treatment, as well as for an increased output of medical and surgical material of both standard and improved types. The exhibit, therefore, will be of added interest to every physician, especially those who are already in or expect to enter the M. R. C.

The idea that these exhibits are for the sole fulfilment of a trade purpose may be dismissed, because nobody will be urged to buy. Everybody will be free to examine every article shown, ask questions, make suggestions and leisurely study the advantages to be derived from the combination of science and industry as applied to the manufacture of the implements of medical and surgical practice.

Every Fellow should visit the exhibits. Your presence and interest will encourage the exhibitor, and will reward him in part for the painstaking efforts and expense in preparing his display for your inspection. Do not hesitate to approach him and ask for information. Be free with your questions. Let him have your doubts or opinions.

A glance at the following descriptions of the features of some of the proposed exhibits will emphasize the fact, which has often been commented upon, that the physician here will have at his disposal the market place of the world for practically everything needed in his work. We wish it had been possible to present in this issue a brief advance description of the exhibit of every firm in the hall,

for the benefit of those who will attend the convention. Unfortunately, however, some exhibitors were *not in position* to say what they would feature in their exhibits; others undoubtedly intended to supply us with this information, but delayed or overlooked doing so in sufficient time for publication.

BOOKS

A glance at the names of the publishers who will be represented readily suggests an excellent and varied showing of medical books. By spending a little time with the representatives of these Publishing Houses the conventionist can conveniently acquire in a comparatively short time a general idea of what is new and worth-while in the way of medical literature.

—Chicago Medical Book Co., Spaces 46 and 48, will exhibit a line of the latest Medical and Surgical books of all publishers, American and English, special attention being paid to War Monographs.

—Besides the usual features of their list, F. A. Davis Co., Space 63, will exhibit several important and novel publications. Notable among these will be the new DaCosta Handbook of Medical Treatment, in two handsome volumes, Geiger's "Modern Operative Bone Surgery," and a unique book on Psychiatry by Chase entitled "*The Ungeared Mind.*"

—Lea & Febiger, Space 15, will submit for inspection their new books and new editions, among which will be found the following: "Thyroid Glands," a new work by Crotti; also the new Urology, in two volumes, by Cabot; Simon's "Clinical Diagnosis," new 9th edition; Cushny's "Therapeutics," new 9th edition; Aaron on the Digestive Organs, new 2d edition; Pocket Formulary, new 11th edition, and others.

—L. S. Matthews & Co., Space 51, will exhibit not only a line of up-to-date medical books of all publishers, but original editions of Beaumont, Laennec, Frost, and a number of other interesting antique volumes. Mr. Matthews will be in charge.

—The C. V. Mosby Co., Space 14, will show their complete line of new and standard publications. Among the new books shown will be Crossen's Gynecology, Sluder's Headaches and Eye Disorders, McDill's Tropical Surgery, Morse's Emergencies of a General Practice, and Luys-Wolbarst on Cystoscopy, also The Journal of Laboratory and Clinical Medicine and The American Journal of Syphilis.

—Oxford University Press, American Branch, Space 93, will show new sets, among which are the Oxford Medical Classics, consisting of seven works selected from the two hundred monographs comprising the Oxford Medical Publications; also, the Oxford Loose Leaf Surgery set with its quarterly supplementary service. Its contributors are Burghard, Kanavel, Penhallow, and other American and English authorities.

—Rebman Co., Space 11, will have as their main attraction a demonstration of the manner in which colored pictures of Skin Lesions and other pathological conditions should be prepared for medical book work.

—W. B. Saunders Co., will exhibit at Spaces 43 and 44. Besides the new editions of many of their standard publications, they will show a new three-volume work on surgery, Warbasse's "Surgical Treatment;" Harvey Cushing's "Tumors of the Acoustic Nerve and the Syndrome of the Cerebellopontile Angle," the current volume of "The Mayo Clinic," Ewing's "Neoplastic Diseases," Koll's "Diseases of the Male Urethra," and several new books of special appeal to physicians in the national service, such as Albee's "Orthopedic and Reconstructional Surgery," Mock's "Industrial Medicine and Surgery," Leo Mayer's "Orthopedic Treatment of Gunshot Wounds," the new edition of Keen's "Treatment of War Wounds," and Sir Berkeley Moynihan's "War Surgery."

—The Southworth Co., Publishers, Space 33, will feature the "American Atlas of Stereoroentgenology," "Pediatrics" by Dr. Dunn, "Tuberculin and Vaccine in Tubercular Affections" by Dr. Bonime, and "Rational Therapy" by Dr. Lerch. They will also have some works on Surgery.

—The Year Book Publishers, Space 61, will present the initial volumes of the Practical Medicine Series for 1918. The purpose of this series of Year Books is to furnish a permanent and comprehensive record, in systematic text-book form, of all that has been thought and done in recent Medicine and Surgery.

FOODS AND BEVERAGES

The producers of Foods and Beverages who will be represented in the Hall have contributed considerably toward the solution of the dietetic problems which years ago puzzled the average physician. Aside from seeing the newer preparations the visitor at these booths will gather information which can be used to advantage in every day practice.

—Borcherdt's Malt Soup Extract, the first American Malt Soup Extract to replace the German product, will be of most interest at the exhibit of the Borcherdt Malt Extract Co., Space 64. Borcherdt's Malt Sugar will also be shown. The simplicity, convenience and facility with which Dri-Malt Soup Extract and Dri-Malt Soup Extract with Wheat Flour may be used to make Malt Soup will be demonstrated.

—The Horlick's Malted Milk Co., Space 100, direct attention to the display they propose to have at the forthcoming Exhibition, where two or more representatives will be in attendance to distribute samples and furnish information regarding Horlick's Malted Milk.

—Mead Johnson & Co., Spaces 18 and 19, will exhibit Mead's Dextri-Maltose, a non-proprietary malt sugar, a highly assimilable, easily tolerated form of carbohydrate for use in infant feeding. They will also exhibit Mead's Dry Malt Soup Stock, which can be used the same as liquid malt soup.

—The Kaffee Hag Corporation at their exhibit, Spaces 73 and 74, will show the evolution of coffee from the blossom to the caffeine-free article. Kaffee Hag will be brewed and served to all visitors without charge. All are invited to register at this booth, so that a full size package may be sent to their home addresses.

—The Mellin's Food Co., Spaces 37 and 38, extend a cordial invitation to all physicians to visit their booth and become familiar with the composition of Mellin's Food and to discuss the practical application of a maltose and dextrin product as a modifier of milk, which is the subject of serious interest to all physicians.

PHARMACEUTIC AND BIOLOGIC PRODUCTS

A representation of well-known Pharmaceutical Houses with a multitude of standard products will greet the visitor this year. Much can be said of the commendable way in which these firms have striven to supply the profession with goods of quality and dependability. Their efforts in this direction we believe are universally appreciated, and merit and the cooperation of the profession.

—The Abbott Laboratories, Space 102, will exhibit the Dakin war antiseptics—Chlorazene, Chlorazene Surgical Cream, Chlorazene Surgical Powder, Dichloramine-T and Chlorcosane (Dakin's single solvent for Dichloramine-T), also Parresine, the improved wax dressing for burns, Neutral Sodium Soap, Barbital and Procaine. Moving pictures will demonstrate the technic and application of Parresine for burns, as well as the use of Parresine and Dichloramine-T.

—Armour & Co., Space 39, will exhibit a full line of organotherapeutic agents and preparation of the Endocrine Glands, showing surgical catgut ligatures and sutures of the highest quality manufactured from material selected at the source of supply.

—B. B. Culture Laboratory, Space 27, will exhibit its product, B. B. Culture, a liquid suspension of Bacillus Bulgaricus. The advantages of this preparation as a biological antiseptic in external and internal use will be explained.

—Fairchild Bros. & Foster, Space 1, will exhibit Gastron, the new entire gastric-gland extract, alcohol-free; Pepton (Bacteriological); Enemose, for colonic alimentation; Holadin, entire pancreas extract in enteric capsules; Bile Salts, the sodium glycocholate and taurocholate in their native association, separated from fresh ox gall; Fairchild Culture (and Tablet) of the Bacillus Bulgaricus, products of timely and seasonal interest.

—Farbwerke-Hoechst Co., table space, will display their American-made Salvarsan (Arsphenamine) and Novocain (Procaine). Their efforts will be directed to informing physicians regarding these and the administration of arsenical preparations. They will also display such apparatuses and chemicals as are usually employed in connection with the former products.

—Hynson, Westcott & Dunning, Space 12, will feature an interesting line of unique diagnostic apparatus and Standard Pharmaceutical Products. Their specialties are familiar to the Medical Profession, but many physicians have not seen or handled their colorimetric appliances, functional tests and suspensions for intramuscular injection. Attention will be directed to corpus luteum preparation, Lutein, bulgarian bacillus in tablet form only, and a standardized ox-bile product in both tablet and capsule form. The Davis Vacuum Apparatus for automatic suprapubic drainage (new) will also be shown.

—The Maltbie Chemical Co., Space 76, will exhibit Calcreose, a new combination of calcium and creosote. The exhibit will consist of samples of the product as contained in the original packages and also of photographs depicting the process of manufacture of Calcreose.

—H. K. Mulford Co., Space 57, aside from displaying a complete and descriptive line of Biological products, will especially feature Antipneumococcic Serum. Antimeningitis Serum. Typho Serobacterin and Hay Fever Pollen Extracts, which should be interesting to physicians, especially at the present time when so many of these products are being used at home and abroad.

—Radium Chemical Co., Space 9, will display their new flat surface, glazed face and gold back indestructible dermatological applicator and the tube applicators containing twenty-five and fifty milligrams of radium. A representative will demonstrate the theory and practice of radium application.

APPARATUS

Manufacturers of Apparatus, of all types for practically every purpose, will offer an exceptional opportunity for inspecting the newer devices that have come upon the market within the last year or so.

—W. D. Allison Co., Space 82, will exhibit their general line of physicians' furniture, including their representative styles of chairs, tables, cabinets and accessories.

—A. S. Aloe Co., Space 56, will feature Microscopes, Blood Pressure Apparatus, High Frequency Machines, Carel-Dakin Outfits, Carbon Dioxide Apparatus, Surgical Equipment, and Surgical Instruments generally.

—The exhibit of Becton, Dickinson & Co., Spaces 24 and 25, will feature B-D Fever Thermometers, Genuine Luer Syringes, Yale Quality Needles, Asepto Plungerless Syringes and Bender's Ideal Bandages.

—Wilmot Castle Co., Space 84, in addition to showing their regular line of equipment, will feature the Castle Rochester Electric Sterilizer, which is now offered mounted on a white enameled stand. Where a table is not already provided for the sterilizer this mounting has proved exceptionally convenient. On the front of the stand there is a drop shelf handy for instruments either coming out or going into the sterilizer.

—The Central Scientific Co., Space 80, will exhibit a line of electrically heated devices for the Bacteriological and Clinical Laboratory, designed by Captain A. deKhotinsky. The line includes Constant Temperature Incubators, Paraffine Ovens, Sterilizers, Wassermann Baths, Hot Staining and Fixing Apparatus, and Cremators for Inoculating Needles.

—The DeVilbiss Mfg. Co., Space 49, will interest visitors with their Theromer Wax-Sprayer as is used in the treatment of burns. They will demonstrate two different types of this instrument, and will also show a complete line of their well known nose and throat Atomers, Nebulizers and Powder Blowers for both office and prescription use.

—The Foregger Co., Inc., Space 7, will feature two Inhalers which are now under construction. They will be of interest to members of the M. R. C., as well as practicing physicians.

—The Halverson Co., Space 50, will conduct an interesting display of their sterilizers, featuring the Surgical Halverson outfit. This sterilizer has three different degrees of heat, is equipped with two red signal lights, one indicating low heat, one medium heat and both extreme heat. It can be furnished with a warmer attachment for three spray bottles or for tumbler and spray bottles.

—The Heidbrink Co., Space 32, will feature the Heidbrink Automatic Anesthetizer (surgical unit), with new Automatic Obstetrical Attachment, also Improved Heating Devices for Anesthetizer and Tank Regulators.

—Scanlan-Morris Co., Spaces 71 and 72, will exhibit a number of new articles of their own design and construction. Among a number of other articles, one of their new type Balfour Operating Tables, a new infant incubator and bed designed by Dr. Julius H. Hess, and a new physician's office and examining table will be shown.

—C. M. Sorensen Co., Inc., Space 62, will show the different models of the Sorensen Tankless Air Compressors, with demonstrations of the use of the Yankaurer outfit, during Tonsil and Adenoid Operations, also the demonstration of the Dr. L. H. Coffin Combination Sinus Apparatus.

—C. J. Tagliabue Mfg. Co., Space 42, manufacturers of High Grade Scientific Measuring instruments, will exhibit among other instruments their new "Tag-Roesch" Sphygmo-manometer. Mr. P. L. Brand, their Associate Manager, will probably have charge of the exhibit, and will give every interested visitor a demonstration of this popular Blood Pressure apparatus.

—The Taylor Instrument Co. have engaged a private room on the floor (Spaces 122 and 123) with the remainder of the exhibits, where they will be prepared to meet physicians and show them the TYCOS diagnostic products, including the Self-Verifying Sphygmomanometer, special Urinalysis Glassware, etc. At this convention will be offered their new book entitled "Blood Pressure Simplified," which has been prepared by their Medical Department and is a condensed and convenient book of information on blood pressure work.

—Toledo Technical Appliance Co., Space 8, will have their Dr. McKesson present to demonstrate the McKesson Nitrous Oxid-Oxygen Apparatus. This machine was selected by the American Red Cross for service in France.

INSTRUMENTS

The Surgical Instrument industry has been more or less handicapped since the war began by reason of the shutting off of importations. However, this has had its good effect in the increased production and development of American-made instruments. Therefore, the conventionist may be assured of a wide variety of instruments of new and improved type.

—The Bard-Parker Co., Inc., Space 92B, will exhibit the Eynard line of catheters, drains, etc., in addition to a special line of Ureteral Catheters, both regular and X-Ray, and the Bard-Parker Knife, the features of which have been repeatedly announced to our readers through the advertising columns of The Journal. An inspection of this exhibit will be well worth while.

—Frank S. Betz Co., Spaces 40 and 41, will, as usual, exhibit a line of instruments, sterilizing equipment, furniture, radiographic and electrotherapeutic apparatus and supplies, as well as a new line of diagnostic instruments introducing a number of novel features.

—V. Mueller & Co., Spaces 94 to 97, will have an extensive exhibit of instruments for every branch of surgery, including practically everything that is new in instruments and apparatus for their particular line of work; instruments for vascular surgery, electrically driven bone surgery apparatus, electrically driven anesthesia and suction apparatus. In addition there will be a complete collection of illuminating and exploring instruments for use in every cavity of the body.

—Sharp & Smith, Spaces 112 and 113, will exhibit their latest and most improved designs of instruments, including many new patterns, and will demonstrate many new items.

—The exhibit of George Tiemann & Co., Space 69B, will contain many new and interesting instruments of their high grade steel specialities, also the Flagg anesthetic apparatus, Forbes electric aspirator, Kemp Proctoclysis apparatus, Ideal electric ophthalmoscope, Tiemann aural suppression apparatus, Paraffin theromer and Baumanometer.

—Truax, Spaces 125 to 129, will exhibit a line of surgical instruments, physicians' supplies with special reference to office equipment, also a line of sundries. In other words, everything that a physician uses, either for himself or for his patient, will be displayed.

ELECTRO-MEDICAL APPARATUS AND DIAGNOSTIC EQUIPMENT

Scientific developments in Electrotherapy have contributed new types of equipment, that may be seen at the booths of the firms listed under this classification. Advances have also been made in the construction and variety of Electrical Diagnostic equipment.

—The American Surgical Specialty Co., Space 32, will exhibit a line of Electrically Lighted Diagnostic and Operating Instruments covering the field of Oral and General Surgery. A special feature will be the demonstration of a surgically clean and perfectly cool diagnostic lamp and the adaptation of standard lamps and batteries to the every day necessities of the active practitioner.

—The Chicago Surgical Electrical Co., who will occupy Space 59-60, are going to display a new Laboratory Table, which they claim will solve many of the problems now confronting the physician, who wishes to do his own laboratory work. They promise a "working" exhibit, which should prove interesting to the visiting physician.

—Hanovia Chemical and Mfg. Co., Space 101, will show in operation some highly developed therapeutic apparatus for application of ultraviolet rays, among which will be featured the Kromayer and Heraeus Sun Lamps. It will be to the advantage of the visiting physician to see this exhibit and investigate the usefulness of this line of equipment as applied to his work.

—The Weder Mfg. Co., Space 91, will exhibit their De Lyte Surgeon. In c junction with this will be their Simplex Surgeon Emergency Surgical Case. The Wistamponade will also be an interesting demonstration.

X-RAY EQUIPMENT

Physicians who do x-ray work will be much interested in the new and improved types of equipment which will be offered for inspection. Demonstrations in the use of x-ray and high frequency apparatus to meet all requirements will be given. These exhibits will, undoubtedly, give evidence of the progressive spirit and willingness on the part of the manufacturers to cooperate with the medical profession in producing superior apparatus to meet the demands of scientific up-to-date roentgenology.

—The American Photo Chemical Co., Space 85, will demonstrate their Diagnostic X-Ray Plates. Every physician who does x-ray work will be interested in this exhibit and is urged to witness the demonstrations that will be given.

—Geo. W. Brady & Co. will exhibit in Spaces 16 and 17 some curious and interesting X-Ray plates, and dental films, also developing tanks, intensifying screens, dental film mounts, and various X-Ray specialties. Cellosilk, a new surgical dressing material, will also be shown in various forms.

—The Eastman Kodak Co., Space 98, will have an exhibit which will appeal to the modern roentgenologist. Dark-room equipment and aids to better photography will be exhibited.

—H. G. Fischer & Co., Spaces 4 and 5, will have an array of Electrical Treatment Equipment, Combination Equipment, featuring such valuable modalities as X-Ray, Diathermy, d'Arsonval, High Frequency, Cautery, Sinusoidal, Tankless Compressed Air, etc., X-Ray Tube Stands, X-Ray Tubes of all kinds.

—The Wm. Meyer Co., Space 65, will show as items of special interest, its Multoscope, an apparatus combining a horizontal stereoradiographic table, vertical, horizontal and angular radioscope and tube stand, with several exclusive features, also a new Klinoscope for vertical, horizontal and angular fluoroscopy.

—The Standard X-Ray Co., Spaces 34 and 66, will exhibit the three types of Standard Interrupterless Transformers together with all of their accessories. Their main attraction, however, will be the new Standard Radiographic, Stereoscopic and Combination Fluoroscopic Tilt Table. This will be its first presentation to the medical profession.

—The Victor Electric Corporation, Spaces 105 to 108, will have on exhibition a representative line of modern X-Ray, Electro-Medical and Physical Therapeutic Apparatus. Roentgenologists will find it of interest to look over this exhibit for new and useful suggestions.

—The Vulcan Coil Co., Space 90, will exhibit models of moderate priced Vulcan X-Ray and High Frequency Treatment Apparatus. Attention is directed to their sectional apparatus, so designed that the Roentgen-Ray Machine is used as a base and treatment units may be added as required.

—Wappler Electric Co., Spaces 118 to 121, inclusive, will exhibit the Bellevue Model X-Ray machine, Auto Transformer Control with [illegible] steps, Auto Transformer 20 step [illegible]tats; a new Coolidge Filament Transformer, High Frequency apparatus known as the Telatherm, Telatherm Jr., Army size, also Genito-Urinary instruments, such as the new Buerger Universal Urethrascope and the convertible double catheterizing and operating Cystoscope.

OPTICAL GOODS

The Government's large demand for lenses has had its effect upon the optical trade, but not so strongly as to deny the medical profession of this country to any appreciable extent the required quantities of optical goods. There will be a good representation of optical firms at the meeting, and it will, undoubtedly, be to the interest of the physician to visit these exhibits.

—Bausch & Lomb Optical Co., Space 23, will demonstrate their FFS-8 Microscope of high precision, APS Microscope, portable form, Model B Balopticon, for projection of lantern slides for educational work, Centrifuge, for field work, Ophthalmic Test Frame and Lenses designated in Vertex Refraction, Keratometer, Exophthalmometer, Interpupillary Distance Gauge and Corneal Microscope.

—The General Optical Co., Space 10, will show the Universal Ophthalmometer, Hare Automatic Self Registering Perimeter, as well as a full line of Genothalmic Instruments for the busy oculist.

—F. A. Hardy & Co., Spaces 109 to 111, will exhibit a line of eye, ear, nose and throat surgical instruments and ophthalmological devices. Among the new surgical instruments to be shown are the new Mouth Gag devised by Dr. Frank Allport, Dr. O. J. Stein's Tonsil Snare, and some new Frontal Sinus instruments devised by Dr. Otto Freer.

—E. B. Meyrowitz, Inc., Space 88, will demonstrate a new test type cabinet arranged for operation from the examiner's station and affording four changes of test types. The mechanism is entirely mechanical, there being no electrical parts requiring renewal or attention. A Peters Campimeter, Herbert Ocular Muscle Test, a complete line of electrically lighted operating instruments and a new operating lamp will also be shown.

—Woolf Optical Instrument Co., of New York City, Space 36, will show a complete line of ophthalmic equipment including useful aids for the scientific refractionist. They will feature the Ski-optometer with its new automatic cylinder attachment. Scientific demonstrations will be cheerfully given.

ORTHOPEDIC AND SUPPORTIVE APPLIANCES

The exhibits of these firms cover a wide range, all of importance to the specialist and the general practitioner.

—Ambulatory Pneumatic Splint Mfg. Co., Chicago, Space 92A, will demonstrate the Ambulatory Pneumatic Splint, also its adaptability for the reduction of a fracture of the hip, thigh, leg or ankle, and treatment of the patient, both in and out of bed, as soon as applied. The company will also show various styles of their Ambumatic Binders, and other surgical and corrective orthopedic appliances.

—Anatomik Footwear Co., Space 21, will demonstrate Anatomik shoes for the prevention and relief of foot troubles of men, women, and children.

—The Berger Brothers Co., Space 75, will demonstrate the Spencer Rejuveno Supports for enteroptosis, Sacro-Iliac Strain, Hernia, post-operative and maternity supports, Corsets for women, belts for men. The Spencer system of designing a special support for each separate patient so as to meet the patient's individual needs will be explained.

—Carnes Artificial Limb Co., Space 35, will give practical demonstrations of their artificial hands and arms. Each of the demonstrators has had one or both arms amputated, which have now been replaced by the Carnes Arm. The men will be glad to demonstrate how practical a mechanical arm may be.

—The Tetra Co., Space 9, will demonstrate the well known Tetra Bandage. The Tetra figure, showing the various purposes of the Bandage, will be represented on colored glass, lighted. Physicians attending the demonstration will receive samples.

—The Wright Wire Co., Space 89, will show the application of Excelsior Universal Wire Gauze Splint which has been responsible for a marked advance in the treatment of fractures both in America and Europe.

MISCELLANEOUS

Under this classification are the firms whose products or service cannot well be listed under any of the foregoing classifications.

—Realizing that it would be of interest to conventionists, the Albuquerque Chamber of Commerce has determined to use their space (124) as a bureau for the dissemination of information concerning health and climatic conditions in the Southwest. The booth will be in charge of a member of the Chamber of Commerce who is conversant with health and other conditions in New Mexico.

—At the exhibit of the Earnshaw Knitting Co., Space 29, their nurses will demonstrate on models the pinless and buttonless method of dressing the baby. Physicians who in their practices have occasion to consult with the mother as to the correct clothing for infant and child will be benefited by seeing this demonstration.

—The Flaxal Pure Linen Mesh and the Wallace French Linen Underwear will be exhibited by The Linen Underwear Co., Greenwich, N. Y. This underwear is of knitted cloth designed as proper, hygienic, and comfortable underwear.

—The National Pathological Laboratories, of Chicago, New York and St. Louis will occupy Space 47, where will be given practical demonstrations of modern and up-to-date laboratory work, such as the complement fixation tests for syphilis and gonorrhea. Modern bacteriology showing aerobic and anaerobic cultures and different organisms under the microscopes, also tissue diagnosis showing sectioning and microscopical exhibits.

—The exhibit of Weissfeld Bros., Space 67, will show up-to-date and improved hospital clothing. Useful souvenirs will be given to all who call to inspect this exhibit.

THE ATROPIN TEST IN THE DIAGNOSIS OF TYPHOID INFECTIONS

ALFRED FRIEDLANDER, M.D. (Cincinnati)
and
CAREY P. McCORD, M.D. (Detroit)
Chiefs of Medical and of Laboratory Service, Respectively,
Base Hospital
CAMP SHERMAN, CHILLICOTHE, OHIO

With all appreciation of the minimizing effect of typhoid-paratyphoid prophylaxis on typhoid infections in army camps, it is still reasonable to anticipate the occurrence of occasional camp cases. The larger number of such cases will probably arise from among unvaccinated civilian workmen and from the improperly vaccinated soldier. In typhoid infections appearing in persons who have received typhoid prophylaxis completely or incompletely, the disease will usually be characterized by such mildness as not to present the outstanding features of typhoid that so readily permit a diagnosis among the unvaccinated. Facing this difficulty in the recognition of typhoid existence, those medical officers responsible for the prevention of infectious diseases in army camps, and those on whom will devolve the care and treatment of suspected cases, are evaluating all recent developments purporting to be of additional diagnostic aid. At a similar period in the making of the British Army there came into use the atropin test as a means for the detection of typhoid infections. The British Medical Research Committee has sanctioned this test's reliability to the extent of issuing a monograph on the subject, prepared by Marris.[1]

In this hospital up to the present time no cases of typhoid have occurred; but in order to be conversant with the merits and technic of the atropin test against the contingency of typhoid outbreak, 228 cases of diverse diseases other than typhoid and paratyphoid have been tested in the manner described by Marris. The results form the basis of this report.

THE RATIONALE AND TECHNIC OF THE ATROPIN TEST

According to the sponsors of this test, the normal individual or the patient ill of diseases other than typhoid infections responds to the administration of atropin with a noteworthy increase in heart rate. In typhoid patients, however, this acceleration either does not occur or occurs to a lessened degree. This difference is attributed to an antagonism of action between the alkaloid and the toxins produced by the organisms of the typhoid group. This relative lack of response to atropin is the basis of the test, the application of which is as now noted:

> The patient lies horizontally and is instructed to remain completely at rest throughout this test, which is not employed until at least one hour has elapsed from the last meal. The pulse rate is counted minute by minute until it is found to be steady; ten minutes of such counting usually suffices. Atropin sulphate is then injected hypodermically in the dose of 1/33 grain, preferably over the triceps region to insure rapid absorption. An interval of twenty-five minutes is allowed to elapse, and the pulse rate is again counted, minute by minute, until it is clear that any rise which may follow the injection has passed off; fifteen or twenty minutes may be necessary for this purpose when the pulse rate is raised at the first count.

If, for example, a near constant pulse rate of 70 was exhibited at the preliminary counting, and a maximum of 96 was exhibited as the pulse rate subsequent to atropin injection, the inference after this acceleration of twenty-six beats per minute would, under the provisions of the test, be that the condition was not typhoid. If, however, the rate after atropin had attained only to 78 beats per minute as the maximum, the inference is tenable that the existing condition is one of the typhoid group. The test does not discriminate between typhoid and paratyphoids A and B. In Marris' report, the line of demarcation for the interpretation as existing typhoid or nontyphoid is placed at 15; that is, if the acceleration following atropin is less than fifteen beats per minute, typhoid is indicated; if the increase is fifteen or more per minute, typhoid is not indicated. A "positive" atropin reaction is one giving rise to little or no increased heart rate after atropin administration (fourteen or less per minute). A "negative" reaction is one giving rise to an increase of fifteen or greater.

> If the patient is admitted during the first fortnight of his illness, the test is applied as soon as possible after admission and is charted with the temperature. When a positive reaction (little or no response to atropin) is obtained, the diagnosis of infection with a member of the enteric group of organisms may be made. In the case of a negative reaction, the test should be repeated after two or three days, and if again negative, it is again repeated. Three negative reactions falling within the first fortnight of the illness exclude the presence of typhoid with a considerable degree of certainty; there are rare exceptions, and in these a continuation of the test is usually suggested by the symptoms and remaining clinical signs.

In the normal individual to whom has been administered 1/30 or 1/33 grain of atropin, some or all of the following manifestations may be expected to occur: A slight and transient decrease of the pulse rate (two or four beats per minute) occurs early with a return to normal. This is followed by a rapid increase in heart rate of from twenty to thirty-five beats. The height of this acceleration is reached in about one-half hour, slowly returning to normal in one or two hours. The classical characteristics of atropin action, lessened secretions and dilated pupils, seldom are observable during the testing period, but at times may be noted within an hour or more subsequent to the testing.

---

[1] Marris, F. A.: Use of Atropin as Aid to Diagnosis of Typhoid and Paratyphoid A and B Infections, Brit. Med. Jour., 1916, 2, 717.

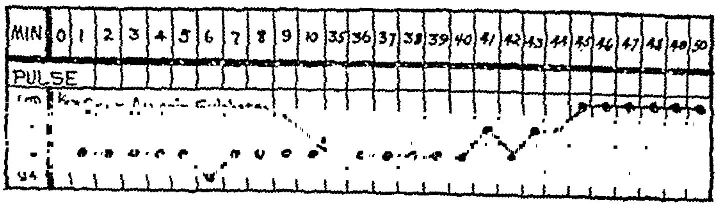

Chart 1.—Typical positive atropin test in measles patient presenting clinical manifestation similar to those of the patient whose reaction is shown in Chart 2. The broken line after the administration of the atropin represents an interval of twenty-five minutes.

Marris' report records 111 cases of typhoid infections in which a diagnosis was definitely established through the isolation of the organism from blood cultures. The atropin test was accurate in 98 per cent. In these cases the pulse acceleration averaged only 6.6 beats per minute. In another group of patients observed by the same writer, of 247 diagnosed by the less definite agglutination method as having typhoid, 222 reacted accurately to the test. Agglutination as a diagnostic procedure has become of less value because of frequent agglutination concomitant to typhoid prophylaxis.

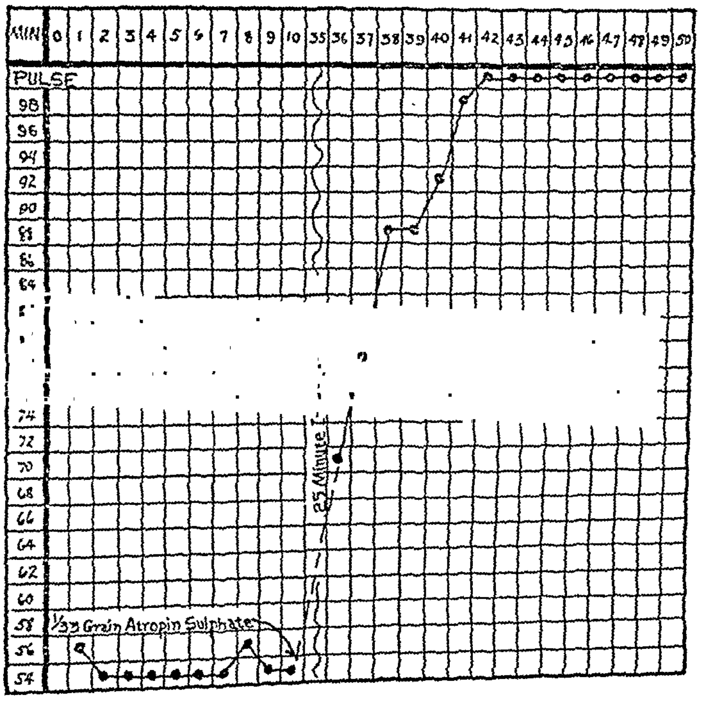

Chart 2.—Typical negative atropin test in measles patient presenting clinical manifestation similar to those of the patient in Chart 1.

At the Royal Victoria Hospital in Montreal, Mason[2] made use of the atropin test as a diagnostic aid during an epidemic of typhoid infections. The technic employed was essentially that described by Marris. In all, 265 tests were made in sixty-three cases of typhoid or paratyphoid. Fifty-six of the number were cases of typhoid fever established by positive blood cultures or by Widal reactions in dilution higher than one in forty. Five of the cases were paratyphoid B, diagnosed bacteriologically, while the remaining two cases were clinically typhoid but the diagnosis was unconfirmed by any bacteriologic or serologic findings. Of the total number (sixty-three patients), fifty-seven were males and six were females; no sex variations were observed. Eleven of the sixty-three failed to give a positive reaction to the atropin test. This departure from the anticipated positive reaction is attributed by Mason to be due in part to the fact that in certain cases only one test was carried out, in part to the restlessness of some of the patients under test conditions. The reaction became positive about the tenth day and disappeared about the thirty-first day of the infection. As a check for these known typhoid and paratyphoid cases, the test was applied to forty-six patients suffering from various clinical conditions other than the typhoids. Forty-three yielded the anticipated negative reaction, averaging in cardiac acceleration 21.5 beats per minute. Three gave positive reactions without any probability of enteric infection. Mason concludes that in the diagnosis of fevers of the typhoid group, the atropin test is of distinct value and in many cases affords diagnostic data prior to a positive Widal reaction.

TECHNICAL DATA FROM THE PRESENT INVESTIGATION

Early in our series of tests it was obvious that our results would be at variance to the foregoing, for which reason it was deemed desirable that our technic should conform in as many respects as possible to the previous work. This necessitated the discarding from our series the results from fifty-eight cases in which technical innovations had been introduced. In the remaining 170 cases, 198 tests have been carried out with rigid adherence to the Marris technic. The patients on whom these tests have been made were all men, predominantly of the third decade. All had received typhoid-paratyphoid prophylaxis. These men were patients suffering from the diverse conditions given in the accompanying table. In one group of 170 cases, 108 (63.6 per cent.) were sensitive to atropin (atropin negative test), while sixty-two (36.4 per cent.) were nonsensitive to atropin, giving the reaction described as typical for typhoid infections. Neither the positive nor the negative atropin tests were sharply associated with any particular conditions. It may be observed in the table that in the various listed processes, the positive and the negative are almost uniformly distributed in the ratios noted above. Charts 1 and 2 are records of the occurrence of distinct positive and negative atropin tests, respectively, obtained in two measles cases similar in clinical characteristics. Charts 3 and 4 likewise were obtained, respectively, in two cases of lobar pneumonia of approximately the same degree of severity and at about the same stage of the process.

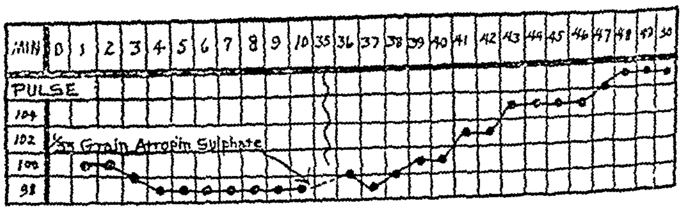

Chart 3.—Typical positive atropin reaction in pneumonia patient whose clinical condition was the same as that of the patient in Chart 4. Broken line, interval of twenty-five minutes.

---

[2] Mason, E. H.: The Value of the Atropin Test in the Diagnosis of Typhoid Fever, Arch. Int. Med., January, 1918, p. 1.

On two successive days the atropin test was made on twenty-seven patients thus distributed: influenza, 11; pleurisy, 3; pneumonia (lobar), 2; pneumonia (bronchial), 1; bronchitis, acute, 4; tonsillitis, 5; ethmoiditis, 1. It was observed that of the total number, fifteen patients were atropin sensitive on both days, four were atropin nonsensitive on both days, and eight were within the limits of atropin positive on one day and atropin negative the other day. The last named group of eight may not be cited as evidence of shifting from an atropin sensitive to an atropin nonsensitive state, for the pulse rate changes were such as to fall in one day's test just above or just below the arbitrarily chosen line of demarcation, and on the following day to fall on the opposite side of the line without there having occurred an actual pulse rate variation of more than six or eight beats. Apart from these borderline cases, the results obtained on the two successive days were closely alike, as shown in the plotted results in one case (Chart 5).

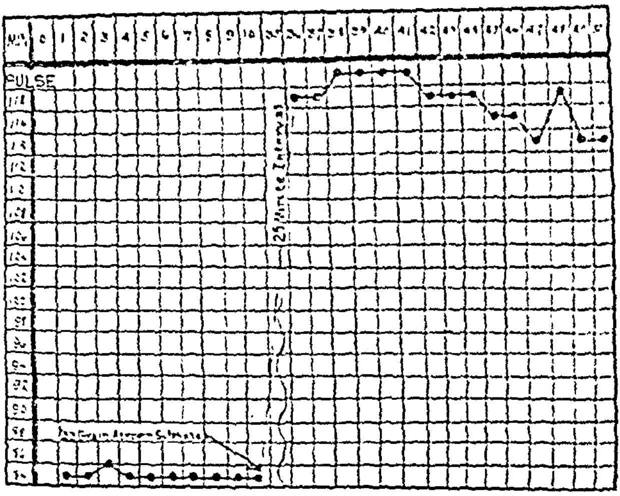

Chart 4.—Typical negative atropin reaction in pneumonia patient whose clinical condition was the same as that of the patient in Chart 3.

RESULTS OF TESTS

Diagnosis	Total Number of Cases	Number Sensitive to Atropin, Negative	Number Nonsensitive to Atropin, Positive
Measles	39	17	22
Scarlet fever	18	6	12
Influenza	23	19	4
[illegible]	8	5	3
[illegible]	1	1	0
[illegible]	2	2	0
[illegible]	6	5	1
[illegible]	22	13	9
[illegible]	3	2	1
Bronchopneumonia	11	9	2
Mumps	1	1	0
Mumps-measles	2	2	0
[illegible]	9	6	3
[illegible]	5	4	1
[illegible]	1	1	0
[illegible]	2	2	0
[illegible]	1	1	0
Adenitis	3	2	1
Gastric ulcer	1	0	1
Intestinal stasis	1	0	1
[illegible]	2	1	1
[illegible]	2	2	0
[illegible]	1	1	0
[illegible], catarrhal	2	2	0
[illegible]	1	1	0
[illegible]	1	1	0
[illegible]	1	1	0
[illegible]	1	1	0
Total	170	108	62

In none of the sixty-two cases giving rise to results that under the provisions of the test would be interpreted as typhoid infections were there evidenced any clinical or laboratory findings that might remotely be attributed to typhoid or paratyphoid fever.

COMMENT

The conception of a specificity of antagonism of action between atropin and typhotoxins is in no way borne out by the results of our investigation. The occurrence of 36.4 per cent. positive atropin reactions in a series of 170 nontyphoid cases removes from this test all but the most casual significance as a diagnostic procedure. The factors that determine the degree of response of the heart to atropin action are fundamentally the outgrowth of variations in the equilibration of the vegetative nervous system. This lack of sensitiveness to atropin is not peculiar to typhoid infections, but is detectable in many diseases and, in fact, may frequently be elicited in normal individuals as a mark of vegetative nervous system instability.

Not only in other conditions than typhoid is this insensitiveness to atropin encountered; but also in typhoid infections marked cardiac acceleration may be observed, according to Matsuo and Murakami,[3] who say: "In our forty-six cases of typhoid fever (including seven cases of paratyphoid B), atropin was quite active, accelerating the rate of pulse, especially in cases of bradycardia. As all our cases were serologically and bacteriologically controlled, the diagnosis was undoubtedly correct." It is noteworthy that such typhoid patients as exhibited a bradycardia exhibited cardiac acceleration after atropin, while the patients presenting a relative tachycardia were for the most part unaffected by atropin. In the series cited by Matsuo and Murakami, all the fatalities occurred among the number giving positive atropin reactions. This observation is in keeping with the well established fact that a tachycardia in typhoid bespeaks a pessimistic prognosis. The atropin reaction for this reason may attain to definite prognostic value.

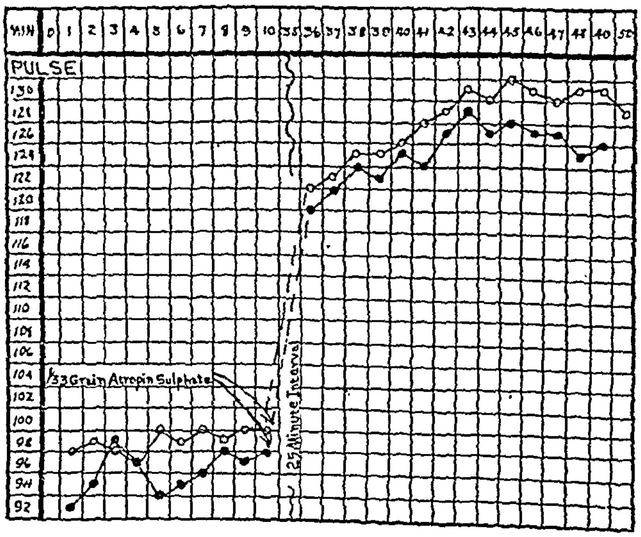

Chart 5.—Conformity of results of two negative atropin reactions made on successive days in a patient convalescing from lobar pneumonia.

SUMMARY

A series of 170 nontyphoid patients has been tested with the atropin reaction in the manner described as reliable for establishing the presence or absence of typhoid or paratyphoid infections. Thirty-six per cent. of the number examined yielded results characteristic of typhoid. Those cases giving reactions typical of typhoid without any evidence of typhoid existence were distributed over thirteen diseases. It is concluded from so high a percentage of discrepancies that the tropin reaction is without especial value in the detec- of typhoid infection.

NURSES AND THE WAR*

PHILIP KING BROWN, M.D.
SAN FRANCISCO

Our advent into the war has shown us unprepared in trained woman power as well as man power, and we are confronted with a need of 30,000 more nurses this year in addition to the 7,000 already enrolled. This means probably one half of the available registered nurses in the United States, and it is safe to say that if the war lasts two years more both the Army and the civil population will suffer immeasurably from the shortage. The fact that France long ago took women for nurses' work who had never had a particle of training marks what must happen to us if some more far reaching plan to meet the demand be not put into operation at once. It is well enough to say that the third year nurses can be taken from the training schools, or that married nurses might be drafted and sent to cantonment hospitals, thus releasing a few thousand graduates for more active duty here or abroad. That is a makeshift and not a solution to the problem.

The Army, on which falls the burden of war, has had to change suddenly all its standards and meet the emergency by making several thousand officers out of a picked number of civilians after an intensive training of three months, supplemented with field work and practice service in cantonments during periods of from three to nine months more. Does any one doubt that these men will make valuable officers, or question the expediency of the new order of education and training? Is it not equally plain that the shortage in nurses should be met in somewhat the same way? It would certainly be better to have an adequate supply of fairly trained nurses than to have to fall back on those who are willing to serve, but who have had no training.

In connection with the subject of the intensive training of nurses, it seems pertinent to raise at this time a few questions about the whole nursing situation. As a profession, nursing has increased with rapid strides in popularity. Better hospitals and more of them have increased the number of permanent positions to be filled, as well as the demand for more pupil nurses. The growth in number of apartment houses drives the ill to hospitals for care, and the expense of good care at home is making the hospital better known and a more and more necessary institution. New nurses from first class sc fc are not now graduated fast enough This de the growing demand, and second to tion is attri schools have to be tolerated in a the fact that in c ies. Then, too, in addition to the out, in part to the nent nurses in hospitals, marriage under test conditio idly from the profession. There about the tenth day lemand for nurses in physicians' first day of the infecti cy hospitals, and welfare departments of large factories and stores, and in public health fields, where they may have the problems of tuberculosis, sanitation, contagious diseases, child labor and the disorders of childhood to deal with, so that a good many of the best nurses never actually practice their profession as private nurses. It is unfortunately too true that there is today no adequate training in many of the fields of special work, and most of the best nurses get their training for the field they finally enter, after they graduate from the training schools. Scarcely a school in the United States in its course for nurses gives training in the understanding and care of mental or tuberculous patients, in public health, or in the consideration of the social, economic and community problems of disease, as they can be studied in a clinic where adequate social service work is carried on, and only a few have anything like adequate service in contagious diseases. Indeed, the training generally in any hospitals that have not large wards is apt to be utterly inadequate, since most patients occupying private rooms have their private nurses, who are a decided menace to the educational opportunities of the pupil nurse.

PRESENT SYSTEM OF TRAINING

A review[1] of the practical educational opportunities offered to nurses in California hospitals (Table 1) will illustrate the decidedly limited scope of the present training, as compared to the whole field of nursing, which must in some way be covered. Reference to the absence of opportunity of studying occupational disease is made because there is no other way a public health nurse may become familiar with conditions we are trying to eliminate than by observing these end-results as they are uncovered in clinics and hospitals.

TABLE 1.—EDUCATIONAL OPPORTUNITIES FOR NURSES IN CALIFORNIA HOSPITALS

Out of 72 schools of nursing, 69 of which are accredited, practical nursing of medical and surgical cases is taught in all.

Obstetrics in	67,	
Nursing of children's diseases in	63,	
Nursing of contagious diseases in	14,	6 of them county hospitals 2 prescribe the course but have no contagious service 1 offers it as an elective, but has no contagious service
Nursing of tuberculous patients in	13.	8 of which are county hospitals
Nursing of mental cases in	4,	in one of which it is an elective
Clinic work is prescribed in	27,	6 of them county hospitals 4 with no clinic service 2 with less than 50 beds 1 elective but no clinic service
Social service in	1	elective
Massage and physical exercise in	0	
Hydrotherapy in	3	
Practical dietetics in	0	
Practical public health in	1	elective
Electives in	9	including 3 months' service in hospital administration, as office assistant, in operating room, children's and contagious diseases, private room service and the public health and social service already enumerated
Occupational diseases in	0	
Work treatment (ergotherapy) in	0	

It is quite evident from this review that there is a grave defect in scope of training in the vast majority of schools in California, and as a matter of fact it is as bad in almost every school in the country. It is sad, indeed, to think that public health and preventive medicine have called forth so meager an opportunity for nurses in the educational world. One seventh of the people in our country die of tuberculosis, and yet special training in the care of these poor unfortunates is denied 90 per cent. of the graduate nurses. The care

2. Mason, E. H.: The Valu Section of the California Association of of Typhoid Fever, Arch. Int. Me April 16, 1918.

[1] The data are gathered from the Survey of Schools of Nursing, a report published in 1917 by the California State Board of Health.

given in mental cases is a still sadder picture. Any one strong enough and as a general rule indifferent enough to the subtle conditions of the human mind seems good enough for the insane, who of all patients need the care and consideration of the finest type of trained and intelligent nurses. Without going further into the entire absence of any training in practical psychology, which is absolutely necessary in a nurse handling nervous and mental patients, and of infinite value to every nurse, it is sufficient to add the statement, made earlier, that most nurses get the training in the specialties, which so many of the best ones enter through force of circumstances or finally follow through preference, after they leave the hospital training schools and too often outside its walls. In a large proportion of these specialties the original training as a nurse, valuable as it is, counts for far less than would justify the three years spent in getting it, plus the uncertain methods of supplementing their fields of vision and operation through the chances opened to them in private work. Indeed, the best workers known to the writer in the fields of public health, mental hygiene, tuberculosis problems and social service are not nurses.

It is particularly noticeable to the close observer in most hospitals that nurses prefer surgical to medical work, and for the reason largely that the battle is short and sharp, full of excitement and interest for a few days, and then the rewards of victory, or the satisfaction of the fight well made and a defeat softened by the consciousness of the greater loss to the family and the need of administering comfort and help to them. There are, of course, plenty of nurses who prefer the surgery because it is easier and the strain apt to be shorter. It offers more variety of a kind easily comprehended because of its mechanical aspect. There is also an undue importance, financial and otherwise, attached to surgery. It is true also that the nurse actually understands the surgical process better than she does the medical, and her interest is correspondingly greater. She administers her drugs largely by hypodermic for definite results. Not so with the medical nurse, whose record of a case shows the administration of a teaspoonful of Prescription 91264 every fourth hour, and a tablet of Prescription 26182 after meals. What she gives and why, she does not know in most cases, and is not supposed to ask.

The first objection, then, to the present system is that it is not well balanced, or is wholly inadequate in many departments in most hospitals, is too apt to be largely surgical, and fails to cover a number of important medical conditions in which special training is necessary.

The second objection is that training schools undertake too much academic work which is out of their line and for the teaching of which they are wholly unfitted. Chemistry, bacteriology, anatomy and physiology, taught from the textbooks, merely represent time wasted; and the danger of the little badly oriented knowledge so gained is extreme. Are any of them really necessary? Frankly no, unless it be anatomy, although young women wishing to specialize in surgery or as laboratory technicians must have a thorough ground work of laboratory training in all four. Some pathology, not taught in any training school that I know, would be an invaluable aid to nurses in understanding disease, if they could have a preliminary course in gross anatomy. The chief point of it all is that except in the necropsy room nurses cannot be taught properly to appreciate disease that they are so vitally interested in combating, and the sight of a nurse at a necropsy is a thing I have rarely seen. Why not figure on an entrance requirement for hospital training schools of all these subjects? Let them be given in a three month period in a medical school, if it is thought best to make them requirements, or let them be left out altogether.

I have considered thus far the subjects that are not taught, though they ought to be, in a well balanced school and the subjects that are badly taught and perhaps ought not to be attempted at all. What can be said of the rest of a nurse's education? First of all, it is an education gained largely by practical experience, during which far too prolonged period the gaps are enormous and are filled in by requiring of nurses much in the way of service that could better be done by maids. A girl is poor material if she has not an idea of cleanliness and order when she enters a training school, and she ought to know how to take care of and pick up a room; indeed, she should know something of the preparation of food before she enters. Given such an equipment, and there remains for the training school to build on this foundation an understanding of how to handle the sick and suffering, administer and apply remedies, including dressings, observe surgical cleanliness, tend to the turning and shifting of the patient, handle the functions of excretions skilfully and tactfully, bathe the patient, make and chart the observations called for, and follow the physician's instructions. Six months of this sort of work critically supervised should make most young women thoroughly fitted to continue it unaided. Three months more might be spent in the operating room, where a thorough training in surgical technic could be obtained, and finally, three months as an elective in that particular line of nursing that the young woman wishes to follow after graduation. These three month periods, for those who do not care to elect Army work, might be continued in the study of elective specialties beyond the one required, enabling the nurse to qualify for several kinds of work so that her field might have more variety. Among these specialties are obstetrics, children's diseases, contagious diseases, tuberculosis, mental disease, medical social service, public health, and in the present emergency, Army hospital work. It is plain that the nurses who go into Army work must have a considerable amount of special training even after three years of hospital, and often many more in private work, because the whole range of Army work is so standardized and at times necessarily is carried on at immeasurable disadvantage. If all pupil nurses of one and a half or two years' training could enter at once cantonment hospitals for three months' training, it would release several thousand nurses for overseas work, and the Army hospitals could be turning out a stream of young women trained for their work. At any time she should be able to reenter any good school for a three month period and get exactly what she has found she most needs, or what would be most useful to her.

It is not my intention to dwell in detail on the many abuses of the present system, but it seems only fair to mention here the lack of reciprocity and coordination among training schools, such as exists among all other educational institutions. A girl may spend two and one-half years satisfactorily in a first class school in one part of the country and of necessity have to leave and perhaps change her place of residence. The principle of crediting her with work done toward her graduation certificate is not an established one anywhere, except that the smaller low grade schools sometimes take such girls and allow them certain time. The system is absolutely unjust, and with the proper standardization of teaching it should be changed.

COST OF INSTRUCTION

This brings up the consideration of the question of whether pupil nurses ought not to pay for their instruction instead of being paid for their services while being taught principles and acquiring practice in nursing. Out of the present system have grown abuses on both sides, the long and irregular hours, unsystematic work, unwillingness of schools to recognize and accredit the work done by nurses in other schools, poor teaching of many of the schools, and inadequate training of most of them in spite of the three year periods. On the other side the hospital schools have had to submit to the regulation of an eight hour day, forty-eight hours a week, which from the patient's point of view makes good nursing impossible except in wards. They have had to pay the pupils small salaries, board and feed them, care for them when ill, and furnish in many cases uniforms, laundry and books, not one of which items is a just charge on the hospital, and ultimately on the ill. In the early days of training nurses these things may have been necessary inducements to young women; but they are not necessary today, and the tendency to drop them one by one in the best schools needs encouragement.

TABLE 2.—COST OF EDUCATION TO YOUNG WOMEN, AND THEIR EARNING CAPACITY

	Nurses	Public School Teachers	Social Workers	Private Secretaries	Bookkeeping and Stenography	Full Commercial Course
Length of training	3 years	2-5 years	6 mo.-2 years	8 months	6 mo.	12-15 mo.
Tuition (total)	0	0	0-$250	$115	$85	$150
Board and room per month	0	$25-$40	$25-$40	$25-$40	$25-$40	$25-$40
Books, laundry, clothes, etc., per month	$5	$10	$10	$10	$10	$25
Earning capacity at graduation and later, per month	$130-$150	$70-$105	$75-$250	$75-$150	$35-$175	$35-$175
Cost of living after graduation, per month	$20-$40	$40-$60	$40-$60	$40-$60	$35-$60	$35-$60
Institutional work: earnings per month	$60-$100, including board and laundry					
Public Health work: earnings per month	$75-$100, without board					

Indeed, if a program of intensive training could go through, and nursing as a profession could be put on a proper educational basis, there seems no reason why the nurses should not pay the usual fees for that sort of instruction. Taking the fees charged by schools of civics, applied social science and philanthropy, and the colleges that give such courses the average fees per year amount to from $125 to $150. Western Reserve University, which devotes one year to its public health course, charges $125 for that alone.

A word more should be said about the advantage of an educational standard for a nurse's training in place of the present too largely time standard. There should be no excuse for graduating a girl in one or even three years if her fitness to continue unsupervised is not evidenced by tests of high standard. Finally, there must always be an opportunity for nurses to fit themselves thoroughly in every department of the work and in hospital administration as well as the executive work of supervising the training schools, and the art of teaching. Instead of the passing on of information method too much in vogue now in most schools, the teaching and supervision of pupils must be done by trained teachers. This is a further reason for the charging of adequate fees for the training.

At this time let us look into the relative cost in time and money of nurses' training and that of other professions open to women. Teaching is the largest field, and here we have the alternative of a five year course in the state university leading to a high school certificate, and a two year course in a state normal school leading to a primary and grammar school certificate. The entrance requirements in the two professions are practically the same. The tuition in both cases is free. Board in university and normal school towns will average about $40 a month for the nine months' work. Books, clothing and laundry are extras not demanded of the nurse, for in many schools uniforms, books and laundry are furnished; but these items amount to a good deal for the college or normal school student. Let us put the difference down at the nominal sum of $100 a year. The nurse has four weeks of vacation in her three year course, the embryo teacher from sixteen to sixty weeks, during which time the cost of living is obviously greater for the student. Pupil nurses are paid small sums in most training schools, more recently in proportion to the poorness of the training and consequent difficulty in obtaining pupils. Many good schools no longer pay these salaries, or furnish books or uniforms; but all schools of nursing still provide room and board and more or less absolute boarding school supervision over their pupils. Here enters in one of the most disturbing psychologic problems in connection with nursing. Why should the normal school or college young woman be turned loose in the community to find pretty much her own environment, for which she must pay $40 more or less a month, and the nurse be boarded and held prisoner, except on the occasion of her having time off once a week when she is privileged to go away unaccounted for, for a number of hours. Time was when a nurse did day or night duty or both according to the demands of the work, and she was conveniently housed in order to be on call at any time. This condition of affairs no longer holds in any but very small hospitals, and the need for nurses being boarded and cared for by hospitals does not exist, any more than it does in any other school for advanced training or professional education. The morale of nurses would doubtless improve to a still higher standard if they were treated by hospital authorities in accordance with the established precedent in colleges. Under the present system, nurses are too apt to react immoderately to the small measure of freedom allowed them. We trust them with the very lives of patients, and yet we treat them far too much as if they could not be trusted. There is no reason whatever for hospitals to board pupil nurses; and a huge administrative responsibility, as well as financial burden, will be spared hospitals when this outgrown tradition is set aside, and training schools for nurses are conducted as are technical, normal and vocational schools and colleges.

The cost of education of young women in time and money for the positions of private secretary, bookkeeper, stenographer, social service worker, and the average earning capacity, with possibility of advancement, is shown in Table 2, to which are added the same data regarding public school teachers and nurses.

One cannot but view with distress the situation that holds with public school teachers whose $70 a month at graduation is increased slowly to $105, as a maximum, at the end of eight years. In any survey of the efficiency of our public school situation, one must feel that, considering the time and cost of preparation, the remuneration and the responsibility, it is remarkable how many fine women take up the profession. The long period of vacation, the very limited hours of work each day, the Saturdays and Sundays free, are all favorable conditions; but the nurse has in one sense even greater freedom, vastly more geographic range, wider interests, and a smaller living expense. It is argued by many that the nurses' fees are too high and prohibitively so to the small salaried person. This may be true, and it is possible that the growth in the use of hospitals is dependent on this fact. Even the expense of hospital care is high for the majority, and the health insurance program is the answer offered to this criticism by those who would make generally better care available for every one.

The fact remains that not alone because of war is there a growing demand for nurses, but also in constantly widening fields of public health and preventive medicine, besides the ever present care of the sick and injured. This situation is not being met by training schools, for the field of training in hospital schools is a limited one; nor has any plan yet been seriously considered for meeting it. Such movements as cutting down the hospital training by a year to college graduates who have covered certain courses, as has been adopted by Stanford University and the University of California, the opening, to the same end, of a three months' summer training course at Vassar for preliminary work in anatomy, physiology, pathology, bacteriology, applied chemistry, nutrition and dietetics, household management and hospital economics, are enormous strides in the right direction, but wholly inadequate to the solution of the problem.

Miss Delano,[2] director of the department of nursing of the American Red Cross, has called attention to the fact that special courses of from four to eight months' duration in practical training in public health nursing are now offered in several centers to nurses otherwise qualified who wish to enter the town and country service. The visiting nurse associations in several large cities give field training to such students. Regular eight months' courses are given by Simmons College, Boston, Teachers College of Columbia University in conjunction with Henry Street Settlement, New York, Western Reserve University, Cleveland, and by institutions in several other cities. This only emphasizes the facts already called attention to, that specialties in nursing are best prepared for after graduation, and the three year preparation for them is unwarrantedly long, if not almost wholly unnecessary in many cases.

SUMMARY

1. The 7,000 already enlisted Red Cross nurses have created a noticeable shortage, although they constitute only 6 to 8 per cent. of the supposed total of from 80,000 to 90,000 registered nurses.

2. The need expressed by General Gorgas[3] for 5,000 nurses within two and a half months and a balance of 35,000 within the year cannot be met by volunteers, and it is doubtful if it could be dealt with by conscription in fairness to the community and the nurses themselves.

3. No plan for an adequate supply of nurses has been seriously advocated, although the curtailing of the three year course for certain well educated women, and the provision of special preliminary training enabling others who take it to cut down the three years, are steps in the right direction.

4. The time for a complete change in the nursing situation is at hand, and the change should be made along the lines of (*a*) more fitting preliminary training in subjects that hospitals cannot teach to advantage; (*b*) the cutting of the course in hospitals down to four terms of three months each, for which the young women pay, and during which time they receive more personal supervision from trained teachers, and (*c*) the abolishing of the boarding of nurses in the interests of getting a better class of women, and lessening the expense of operating hospitals.

Health Hazards in the Stone-Cutting Industry.—In *Public Health Reports*, March 22, 1917, Dr. J. P. Leake, passed assistant surgeon, and Dr. D. L. Edsall, consultant in industrial hygiene, U. S. Public Health Service, report on their investigation of the extensive quarrying and stone-cutting industry at Bedford, Ind., relative to the extent to which it affects the health of the workers. The chief attention was given to tuberculosis and the effect on the nervous system of stone cutting, which is done chiefly by compressed air tools. Conditions surrounding the industry were found to be good, the cutting sheds being well constructed and lighted, and conditions for eliminating dust being admirable. Some of the work is done under water spray and some of it dry. The inhalation of dust was found not to be excessive, and the tuberculosis rate in the community among women equaled that among the men; therefore dust was not an important factor in the promotion of this disease. The cutters are men of a superior class, make good wages, work short hours and live well, many in their own homes. The pulmonary hazard is said to be less than in the stone industry in general. In some mills sanitary conveniences and guards against the spread of intestinal infection are satisfactory, but in others improvements should be made. In the hands of stone cutters who use pneumatic hammers, a hypertonicity of the blood vessels was found, appearing as an exaggerated reaction to low temperatures. This is not serious as to life or function, but is uncomfortable and can be overcome to an extent by proper management. Some apprehension exists among some cutters as to the ultimate effects, but Dr. Edsall believes they will not be permanent. The trouble affects chiefly the ulnar side of the hand holding the vibrating hammer, and is avoided by the more skilful operators.

ATONIC DYSPEPSIA

WILLIAM J. MALLORY, A.M., M.D
Associate in Medicine, George Washington University Medical School
WASHINGTON, D. C.

Of all the diseases of the digestive system, the diagnosis and treatment of the so-called functional disturbances are the most unsatisfactory. This is true from the standpoint of both physician and patient. To the physician they present a clinical picture of such complex composition and vague outlines that diagnosis requires unusual care and study. To the patient the variable course and prolonged duration are exhausting, both financially and physically.

Recent accurate work in diagnosis and treatment of the organic diseases of the stomach has been so fruitful that attention has been focused on that class of disseases to the relative neglect of the equally important functional disturbances. The neglect of the functional diseases by both physician and patient is due to the fact that life is rarely threatened, and acute symptoms are not common; but the importance of such diseases is nevertheless great, because of the prolonged impairment of the patient's social and industrial efficiency.

Physicians of the greatest experience repeatedly state that the more common disorders of digestion are functional in character, and of these the most important is the motor disturbance atonic dyspepsia (gastric atony, the anemic-gastroptotic dyspepsia of Cohnheim, and motor insufficiency of first grade of Boas). Which of the foregoing synonyms is most applicable we need not attempt to decide, provided that when we use our chosen term we have a clear understanding of the clinical entity it serves to designate. Briefly, this is an impairment of gastric tonus and motility, without organic obstruction. There is impairment in motility and delay in emptying, but complete emptying nevertheless occurs. Atony is to be definitely distinguished from motor insufficiency of second grade, in which food remains are still found in the stomach twelve or more hours after a test dinner.

Some writers further divide motor insufficiency of the first grade into (1) atony, in which the stomach *does not* contract tightly around its contents, and through the weight of normal amount of food becomes temporarily dilated although emptying in normal time (impairment of peristole), and (2) impairment in peristalsis with delayed emptying, though no twelve-hour stagnation or permanent dilation is found. Such writers hold that impairment of peristole (tonus) may exist alone, but is usually associated with some degree of impairment in peristalsis and actual delay in emptying.

Whether atony should be separated from gastroptosis is well discussed by Cheney, who says:

> The greatest difficulty in diagnosis lies in separating these cases from gastroptosis; for neurasthenic symptoms are common to both conditions; and in so-called atony cases, the weak walls permit the greater curvature to sag below normal limits after inflation by carbon dioxid or after the barium meal for roentgenographic examination. There really seems good reason, therefore, to suspect that the cases we class as atony are in fact minor grades of gastric prolapse, and the neurasthenia is a consequence and not a cause.

In my opinion, if it is borne in mind that the essential feature of disease under discussion is impairment of motor function and tonus, without organic obstruction, the position of the stomach becomes a matter of secondary importance and need only be considered as one of the stigmata of inborn universal congenital asthenia on the basis of which atonic dyspepsia develops, when one or more of the exciting causes are added. Some discussion of these predisposing and exciting factors in the production of atonic dyspepsia is necessary, for if the treatment is to result in any measure of success it must be based on an intelligent effort to eradicate the acquired exciting factors and an adaptation on the part of the patient to those inborn predisposing conditions which cannot be removed.

All the predisposing causes may be summed up under the term "universal congenital asthenia," or the habitus of Stiller, sometimes also known as the habitus of Botticelli, on account of the resemblance to the physique portrayed in the pictures of that artist. The physique is slender and spare. The thorax especially presents characteristic features. The Lenhoff index (that is, the distance from the episternal notch to the symphysis pubis, multiplied by 100, divided by the minimal circumference of the abdomen) is over 80, the costal angle is acute, the tenth ribs often unattached at their costal ends, and the right kidney or both kidneys palpable or movable to a varying degree, with more or less ptosis of all abdominal viscera. The abdominal wall is thin and the muscles relaxed, and a splashing sound is easily elicited. The heart is small and vertically placed, the blood pressure is usually low, the pulse is slow, and the hands and feet are cold.

SYMPTOMS

Temperamentally these patients have characteristics almost as marked and definite as their physical features. They are sensitive, react excessively to normal stimuli, but react inadequately, undertaking more than they can perform, working hard as long as strength lasts, and then, desire having outrun accomplishment, they collapse with some functional digestive disturbance and much mental depression.

With the above-mentioned mental and physical characteristics, the individual may have nothing more serious than occasional complaints of a "weak stomach" till some additional stress is added, which plays the rôle of an exciting cause. This is often some illness such as typhoid fever, influenza, or, in women, a pregnancy or miscarriage. Atonic dyspepsia in its most marked form is especially apt to occur in young adults about the time when they meet the stress of life for the first time, as is seen in young men who work their way through the university or in women who work and also nurse some dependent sick relative. *Mental* and emotional stress, especially if of a depressing type, is an important exciting cause, as is shown by onset of marked symptoms following some shock, material worries, unhappy love affair, or conjugal infelicity.

The subjective symptoms are so characteristic that a diagnosis can often be made without special examination. A most complete and careful examination should never be omitted, however, for although the dyspeptic symptoms may dominate the clinical field, other conditions, such as incipient pulmonary tuberculosis, chronic appendicitis, or other focal infection, may be present and should of course receive weighty consideration when the treatment is directed.

The most common symptoms complained of are a feeling of weight, discomfort, fulness or pressure, occurring either while eating or soon afterward, the patients often complaining that they feel too full even before they have satisfied hunger, and that the sensation is present even after soup, milk or a cup of tea and toast. Nausea, sour eructations, dizziness and headache occur, and there is often complaint that food is tasted long after it is eaten. The last-mentioned symptom leads the patient to think that certain foods disagree, with the result that first one article and then another is omitted until the diet is entirely inadequate and malnutrition develops with the establishment of a vicious cycle. Digestants, sedatives and analgesics fail to give relief, unless one of them contains some ingredient that will produce belching, which nearly always affords some temporary relief. The patients complain of a feeling of general weakness, fatigue and lassitude of the body, with mental torpor and inability to concentrate the attention on work, especially for two hours after meals. Actual pain and vomiting very rarely occur in uncomplicated atony. The appetite is quite variable, both with regard to the quality and the quantity of food desired, and the ability to take certain foods varies from day to day. That is, a meal of certain composition can be taken and digested without discomfort on one day, and a few days later the same food will cause marked discomfort. Constipation is common but not constant. After a test breakfast the amount withdrawn is often increased above normal, and after a test dinner there is more definite evidence of impaired motility. In well established cases, food remains are found seven hours after the meal, but the stomach is found empty twelve hours after eating. The acidity is normal or varies only very slightly above or below normal. Blood and other abnormal constituents are absent.

On roentgenographic examination, the stomach is found to be of the fish-hook type, and the gas bubble is large. When examined with the fluoroscope, the barium mixture, without the usual preliminary hindrance to filling in the upper part of the stomach, sinks rapidly to the caudal part, while the pars media remains empty and collapsed. After 1 or 2 ounces of the mixture are taken, the patients often complain of fulness, saying that they cannot swallow any more as the stomach is already full. Peristole, or the ability of the stomach to contract tightly about its contents, is impaired, as shown by a large gas bubble, and peristaltic action is sluggish. The stomach is nearly always ptosed to a varying degree, but it is a noteworthy fact that neither the impairment of motility nor the subjective symptoms are always proportionate to the degree of ptosis. Position is not a measure of function.

There is little difficulty in recognizing atonic dyspepsia if the history is taken carefully and the symptoms studied intelligently. The false diagnosis of gastritis is the error most frequently made, though it has also been treated as gastric ulcer with the result of producing increased debility instead of improvement. The most serious error that can be made is to overlook some underlying disease such as chlorosis, nephritis or early pulmonary tuberculosis.

The course of the disease is variable from week to week, with a tendency to become progressively worse. Physical fatigue and mental stress increase the severity of the symptoms, while rest and relaxation produce some amelioration. Under the most favorable conditions the disease is essentially chronic.

TREATMENT

The chief difficulty encountered in the treatment of these patients is not found in the disease itself so much as in depressing economical or social relations, which often exert such a definite influence as to merit the title of exciting cause. The problem presented, therefore, is essentially one of adaptation. The physician has the general task of effecting an adequate adjustment between a subnormal individual and the environment.

A special feature of this task is the improvement of nutrition. When it is noted that it is an organ of nutrition that is especially impaired in its function, the difficulties may be realized. Two different methods are employed in treatment. One is the well known rest cure, which consists in changing the whole environment of the patient for the better. All of the exciting and aggravating causes mentioned above are removed by placing the patient at rest in bed in a hospital, or preferably a quiet sanatorium. Not only are friends, relatives and business associates excluded, but even letters and newspapers are forbidden. Contact with the old environment having been thus effectually broken, the patient is fed all of the most nourishing food that can be digested, and an effort is continually made to increase the capacity for assimilation. All hygienic measures that may be of aid are employed. Massage, baths and later moderate exercise, are directed according to the needs of the special case. Finally, and perhaps most important, must be mentioned a skilled and tactful nurse who will not only attend to the actual needs of the patient, but will divert the attention of the introspective patient from within to outward things.

This method, which has been barely outlined above, is usually highly successful — the results are striking, it is a brilliant conquest — that is, till the patient resumes the old life. Then the real test occurs; for if the patient is to take any part in the world, adaptation must take place; not all the handicaps can be removed. Excellent as this method is, it should be reserved for the most severe cases, or those complicated by some other disease. For, although it is so pleasing to physician, patients and friends to see such marked improvement in a short space of time, unless great care is exercised and unless the patient realizes the nature of the problem, all that has been gained while in the sanatorium will be lost in an equally short time, with great disappointment and discouragement to all.

In my opinion the second method, although more difficult for the physician, is to be preferred in all except the most severe and complicated cases, because, although the gain is slow, it is accomplished under working conditions and is therefore more likely to be permanent. In this method of treatment the patient is allowed to continue the normal occupation, business, domestic duties or social activities, but in a slightly modified form. Sufficient time must be allowed for meals, excessively long hours and night work avoided. If possible, an hour of rest should be taken after lunch and a half hour rest before dinner. If the patient is a woman, the household duties may be readjusted and social activities reduced to such an extent as to provide time for one or two periods of rest during the day. It is most important that the meals be taken without hurry and confusion. The excitement, tension and anxiety associated with formal lunches and dinners or with seeing the children off to school, has a most pernicious influence and should be eradicated as far as possible. Dietary errors should be sought for, and when found, corrected. The errors are numerous and peculiar. One patient ate six apples each night, and another drank milk exclusively. The patients, guided now by the advice of friends or something they have read, now by their subjective sensations, make many experiments, but rarely follow any one course long enough to determine whether it is good or bad. The tendency is toward a diet of soup, milk and broth, and raw eggs. The diet really needed is one of highly nutrient value and little bulk. Since the stomach rebels at a normal amount of food at any one time, the alternative is frequent small meals, with a gradual increase in amount. It is especially important that the lunch be adequate in amount and ample time allowed for eating. Discomfort will be present at first, no matter what food is taken; but with encouragement and intelligent direction, the patient may usually be persuaded to continue to eat adequately, especially if a thorough study of the case has been made before treatment is begun. The forced feeding should be continued despite the discomfort. Only real pain or vomiting should indicate a relaxation and change. The often quoted advice to "take exercise, drink plenty of water, and get the fresh air," is vague, indefinite and often harmful. Since such patients are already below normal weight and find difficulty in taking and assimilating a sufficient amount of food, exercise should be reduced where it is possible, and that taken should be in the form calculated to correct some special weakness or restore normal posture and carriage. When improvement is manifest, exercise may be cautiously increased by allowing participation in exhilarating games and dancing, always stopping short of fatigue and following the exercise with a period of rest.

I lay special stress on exercises associated with mental exhilaration, for the good effect of psychic stimulation on the vegetative system is as potent for good as depression is known to be for harm. In this connection it is often beneficial to explain the condition to the patient. Instead of making them more introspective and "neurasthenic," they are usually pleased by a frank prognosis, and encouraged to learn that there is something they can do personally, and that their intelligent cooperation is of much importance.

An abdominal support is of great value; but in order to be effective it must be carefully and accurately fitted, and the patient must be instructed as to how it is to be applied and what is intended to be accomplished. The fact that such supports do not restore the stomach to what is considered its normal position, as revealed by roentgenoscopy, does not negative their usefulness. The elevation of the stomach as much as an inch often relieves the sensation of weight and discomfort when all other methods have failed. When the nutrition has been improved to such an extent that exercises may be taken, then gymnastics such as already referred to become effective, and the sppport may ultimately be adandoned.

In every case it is necessary to impress on the patient the importance of maintaining the improved condition of health that has been gained. Any unusual physical or mental strain is very apt to induce a return of symptoms, and since the underlying cause is largely inherent in the physical and mental constitution of the patient, continued watchfulness and care are necessary on the part of both the physician and the patient in order that the nutrition may be kept at the highest possible level.

RENAL INFECTIONS

A CLINICAL AND BACTERIOLOGIC STUDY*

HARRY CULVER, M.D.
RUSSELL D. HERROLD, M.D.
AND
F. M. PHIFER, M.D.
Captain, M. R. C., U. S. Army
CHICAGO

The whole question of renal infection is complicated by confusing conditions in many phases of the process. The phase, however, that is most complicated and perhaps least understood is that which deals with the routes by which the infecting organisms reach the kidney. Evidence is presented that demonstrates the blood stream as undoubtedly the route of infection in some instances; again there are equally convincing clinical and experimental facts to favor the more or less direct transmission to the kidney through the lymph stream. During the earlier days, it was assumed that all renal infections were ascending directly from the lower urinary tract to the kidney pelvis and parenchyma by way of the lumen of the ureter. This route eventually acquired the disfavor of most of its supporters, who were drawn toward the more attractive hematogenous and lymphogenous theories. For some time the direct ureteral route was considered mechanically impossible excepting in those instances in which there was obstruction to the emptying of the bladder, resulting in dilatation of the ureter and renal pelvis by infected urine. Therefore the solution of this question for a long time centered around the hematogenous and lymphogenous routes, practically all observers agreeing that the clinical and experimental evidence was sufficient to make one suspect one or the other as a possible route in every instance of renal infection. The recent work of David, however, demonstrates that in experimental work renal infection takes place through the lumen of the ureter in most instances, and this in the presence of unobstructed bladders. Just here the confusing condition rests at present, and its solution appears even more remote than ever.

Regardless of the route by which the infection reaches the kidney, there are certain factors within and outside of this organ that predispose it to bacterial invasion. Infection obviously occurs in many previously healthy kidneys; but a kidney already the site of disease, malformation or malposition is known to be relatively more susceptible. Certain diseases more or less constitutional in nature, such as furunculosis, osteomyelitis, teeth and throat infections, and prostate and seminal vesicle infections, as well as gastro-intestinal disturbances, are observed to be closely associated, in many instances, with a homologous infection of one or both kidneys.

While a complete understanding of the factors brought into play in the pathogenesis of renal infection is not possible at present, it is equally impossible in many instances to comprehend the protean nature of its symptomatology. In the usual, typical case there are certain symptoms presented which, to the knowing observer, are logically associated with the pathologic processes as they exist; there are patients, however, whose symptomatology is altogether atypical. The patient's condition often goes on and on unrecognized until severe destruction of the kidney has taken place; and often he is subjected to one or more surgical operations, either on a wrong diagnosis or on the operator's guess that the appendix, gallbladder, ovary or other abdominal organ might be the seat of the trouble.

---

* From the Department of Pathology and Bacteriology, University of Illinois College of Medicine, and the Memorial Institute for Infectious Diseases.

The basis of this report is a study of 116 instances of nontuberculous, nonsurgical, renal infections, with especial regard to symptomatology and bacteriology, together with notes on their treatment.

ETIOLOGY

Thirty-six, or 31 per cent., of these infections were in males, while eighty, or 69 per cent., were in females, and the ages varied from 13 to 57 years. Lesions within and outside of the urinary tract that may have had some etiologic significance are to be seen in Table 1.

Since this table contains only twelve patients with other abnormalities of the urinary tract, and but thirty-six patients with demonstrable conditions outside the urinary tract, sixty-eight patients, or 58 per cent., present themselves with no definite abnormal condition other than the renal infection; however, 24 per cent. of these complained of constipation as a symptom which may rightfully be included as a coincident pathologic condition. Also there are many instances of marked mouth and probably sinus infections in this series that may have a bearing on their coincident renal infection. This factor, however, unfortunately was not investigated in all patients.

TABLE 1.—LESIONS WITHIN AND OUTSIDE THE URINARY TRACT IN INSTANCES OF RENAL INFECTION

Lesions Within Urinary Tract	No. of Cases	Lesions Outside Urinary Tract	No. of Cases
[illegible]	3	Puerperium	12
[illegible]	2	Pregnancy	5
[illegible] ureter	2	Salpingitis	2
Stricture of ureter	1	Peptic ulcer	2
Renal stone (passed)	1	Organic heart disease	1
Septum of bladder	1	Inguinal hernia	1
Cystocele	1	Alveolar abscess	1
Vesicocervical fistula	1	Cervical adenopathy	1
		Tonsillitis	1
		Pharyngitis	1
		Lacerated cervix	1
		Hemorrhoids	1
		Retroflexion	1
		Spondylitis deformans	1
		Dementia praecox	1
		Undescended testicle	1
		Bronchial asthma	1
		Abdominal tumor	1
		Retroperitoneal abscess	1

SIDE INFECTED

It has been said that all cases of renal infection are bilateral excepting instances of septic infarction and those in which there is a preexisting lesion or anomaly of one kidney rendering it more susceptible. Our findings are not in accord with this statement in that only sixty-eight patients, or 58.7 per cent., had bilateral infections, and forty-eight patients, or 41.3 per cent., had unilateral infections. Of the forty-eight unilateral infections, twenty-three, or 48 per cent., were on the left side, and twenty-five, or 52 per cent., on the right side. These findings agree with practically all other statistics in that the right kidney is somewhat more susceptible to infection than the left, the explanation being given that the right kidney is more mobile than the left, and hence more subject to slight trauma.

SYMPTOMATOLOGY

For brevity the symptoms are tabluated in Table 2.

Three symptoms are seen to be numerically prominent in this table; chills and fever, pain in the back, and frequent painful urination. These symptoms may justly be called the cardinal symptoms of renal infection; there are many patients, however, that complain of none of these symptoms and have an infection not to be distinguished pathologically or bacteriologically from those in the first group; hence a detailed enumeration of these less common symptoms is considered of value. It is pertinent to add that the symptoms tabulated are those volunteered by the patients and not secured by suggestion; hence a symptom such as hematuria means a macroscopic hematuria, as microscopic blood in the urine may be found in a very much higher percentage of patients.

TABLE 2.—ANALYSIS OF SYMPTOMS OF ONE HUNDRED AND SIXTEEN PATIENTS WITH RENAL INFECTION

Frequency			First to Appear			Predominant Symptom		
Symptom	No.	%	Symptom	No.	%	Symptom	No.	%
Chills and fever	56	49	Pain in back	55	50	Pain in back	35	30
Pain in back	52	45	Chills and fever	24	20	Abdominal pain	21	18
Painful frequency of urination	46	40	Painful frequency of urination	18	15	Painful frequency of urination	15	13
Constipation	28	24	Abdominal pain	16	14	Chills and fever	13	11
Headache	27	23	General weakness	14	12	Pain in abdomen and back	8	7
Vomiting	26	22	Pain in abdomen and back	10	8	General weakness	6	5
Pain in abdomen	23	20	Pain over bladder	3	2.5	Hematuria	3	2
Hematuria	14	12	Headache	2	1.5	Pain over bladder	3	2
Loss of weight	13	11	Vomiting	2	1.5	Pain in back and legs	1	0.8
Pain in abdomen and back	11	9	Hematuria	2	1.5	Incontinence of urine	1	0.8
Incontinence	6	5	Incontinence	2	1.5	Constipation	1	0.8
Pain over bladder	5	4	Retention of urine	1	0.8	Pain in neck and legs	1	0.8
Retention of urine	1	0.8	Nocturia	1	0.8			
Pain in neck and legs	1	0.8	Pain in neck and legs	1	0.8			
Pain in back and legs	1	0.8	Pain in back and legs	1	0.8			
Nocturia	1	0.8						

Pain in the back varies in type and severity from a dull, aching pain in one or both lumbar regions to a markedly acute pain and tenderness over the entire lumbar region not accurately localized. These pains sometimes radiate or are referred down to the bony pelvis and in some instances into the thigh, occasionally simulating a ureteral colic which may actually occur from the passage of cell detritus. The more acute of these "back pains" are often associated with even more distressing abdominal pain; or the latter may be the only pain present. It may be a diffuse pain not especially severe, or have the general aspect of an "acute abdomen." Keen diagnostic judgment *is often necessary to rule out the abdominal* contents as the cause of these symptoms, and in not a few instances the abdomen is unnecessarily explored.

The temperature produced by these infections is even more variable than the other symptoms; but in a general way it may be said that the more acute and severe the infection, the higher the fever may rise; while the chronic infections seem to produce no fever whatsoever. In practically all instances, the fever is of an intermittent type. Our series contains thirty-five patients, or 30 per cent., with normal temperatures; thirty-one patients, or 29 per cent., with a temperature ranging from 101 F. to normal; twenty-one patients, or 18 per cent., with 103 F. to normal, and twenty patients, or 18 per cent., ranging from 105 F. to normal.

LABORATORY DATA

Blood.—Leukocyte counts of the blood were made at various times during the course of the infection, usually at the time of the first examination. Some of the patients had had symptoms intermittently for ten years, while the more acute infections were seen on the second day. All grades of chronicity and acuteness between these two extremes were observed, the leukocyte counts varying from 40,000 per cubic millimeter in the most acute down to normal counts in the real chronic forms, the average being 14,000 leukocytes per cubic millimeter.

Bladder Urine.—Of the 116 patients studied, 112 showed leukocytes in the centrifuged specimen of urine which was catheterized from the bladder, while four bladder urines were apparently perfectly normal at the time of the examination, although specimens from these bladders might have contained pus the day before or the day following the examination. Such conditions are known to occur, and in practically every instance leukocytes may be found in the bladder specimen if repeated examinations are made in suspected cases. On one negative urine examination a *renal infection cannot* justly be ruled out.

Cystoscopy.—The ability of the bladder mucosa to protect itself against infection from which it is often in direct contact is very marked, as evidenced by the fact that thirty-nine, or 32 per cent., of these patients had perfectly normal bladders as observed cystoscopically, whereas fifty-nine, or 51 per cent., presented moderate bladder changes, such as hyperemia about the trigon and adjacent mucosa, but usually most marked about the ureteral orifice or orifices from which the septic urine was coming. Nineteen, or 17 per cent., of these patients had marked changes in their vesical mucosa, such as generalized hyperemia, sometimes associated with edema, which is usually localized but may also be more or less generalized. Mucopurulent material clings to the vesical walls, and observation is often difficult, owing to intolerance of the bladder to fluid and inability to get a clear distending medium. *Just this type of infection* is difficult to distinguish from a tuberculous process, and it usually requires considerable local treatment before the primary cause of the bladder infection can be ascertained.

Bacteriology.—A standard method of culture was used. Five drops of uncentrifuged urine from a ureteral catheter were used to inoculate 10 c.c. tubes of blood agar. Plates were made and incubated at 37 C. for from twenty-four to forty-eight hours. At the end of this time, if a culture was *obtained*, the various types of colonies were studied by smear and special stain as indicated. Occasionally it was necessary to make subcultures on special mediums before identification of the organism could be made. No attempt was made at this time to separate the colon bacillus group into its various subgroups.

In common with the usual findings in analysis of this sort, there are found to be two organisms which produce most instances of renal infection, namely, the colon bacillus and the staphylococcus. The number of patients suffering from each infection varies somewhat with each series studied and also with the care exercised in handling the material bacteriologically.

Our findings are not at marked variance with those of others, excepting that our percentage of colon bacillus infections is somewhat higher than usually found. Colon bacillus infection was found in 85 per cent. of our patients, 74 per cent. being pure colon infections. The staphylococcus was found in 19 per cent. of the cases, and 9 per cent. of all gave pure cultures of this organism.

TABLE 3.—BACTERIOLOGY OF ONE HUNDRED AND SIXTEEN INSTANCES OF RENAL INFECTION

Micro-organism	Character	Cases		Right Kidney		Left Kidney	
		Number	*Per Cent.*	*Number*	*Per Cent.*	*Number*	*Per Cent.*
Colon bacillus, pure	Bilateral	54	47.4				
Colon bacillus, pure	*Unilateral*	35	*30*	*17*	*14.6*	*18*	*15.5*
Colon bacillus and staphylococcus	Bilateral	7	6				
Colon bacillus and staphylococcus	Unilateral	4	3.4	2	1.7	2	1.7
Colon bacillus and streptococcus	Unilateral	1	0.86	1	0.86		
Total infections, pure colon bacillus	....	89	74				
Total infections containing colon bacillus	....	101	85				
Staphylococcus, pure	*Unilateral*	3		2	1.7	1	0.86

Staphylococcus and streptococcus	Unilateral	1	*0.86*	1	*0.86*		
Total infections, pure staphylococcus	....	9	8				
Total infections containing staphylococcus	....	*19*	*16*				
	Unilateral	1	0.86	1	0.86		
	Unilateral	1	0.86	....	....	1	0.86
	Unilateral	1	0.86	....	....	1	0.86
	Bilateral	1	0.86				
Leptothrix	Unilateral	1	0.86	1	0.86		
Total bilateral infections	....	68	58.7				
Total unilateral infections	....	48	41.3	25	21.5	23	19.8

Table 3 presents a complete analysis of the bacteriologic findings. The two patients having definite leptothrix infection were under investigation for genito-urinary tuberculosis, since somewhat acid-fast structures had been found in the bladder urine before the patients were seen by us. We found no tubercle bacilli, but repeated leptothrix cultures were obtained. These organisms resist *destaining with acid alcohol* in weak concentration or for short exposures. It is easily possible that a wrong diagnosis may be made from this finding.

DIAGNOSIS

A diagnosis may often be made on the *symptoms*, but an absolute diagnosis can be made only by a microscopic and bacteriologic study of the urine collected from each kidney. In Table 4 are enumerated the different diagnoses under which these patients were admitted to the hospital.

In justice to the examining room physicians responsible for these diagnoses, it should be said that they are obliged to make hurried and naturally superficial examinations, as a rule, and often are unable to secure a good history; some of the patients, however, are entered with the diagnosis made by a physician who previously had charge of the patient. While this table represents diagnoses made without thorough study, it at least strikingly emphasizes the conditions that renal infections may simulate and from which they must be distinguished.

TREATMENT

Only thirty of the 116 patients studied were treated until completely cured. Our standard for judging a complete cure was not merely a complete relief of symptoms, but two successive negative cultures from five to seven days apart.

The treatment was more or less routine. Those patients suffering from colon bacillus infections were given internally hexamethylenamin in moderate daily doses for a week, alternating with the administration of alkali for a week. The alkalis were used to the point of securing a distinctly alkaline urine, and for this purpose we used sodium citrate or sodium bicarbonate. In coccus infections, hexamethylenamin was used continuously and prescribed with either acid sodium phosphate or benzoic acid. Regardless of numerous reports to the contrary, there seem to be variable degrees of improvement secured by the proper administration of hexamethylenamin. It is especially noticeable when this drug is alternated with alkalis in colon bacillus infection.

TABLE 4.—DIAGNOSIS MADE IN ONE HUNDRED AND THREE CASES OF RENAL INFECTION

Diagnosis	No. of Times	Diagnosis	No. of Times
Cystitis	12	Pyuria	[illegible]
Pyelitis	10	Puerperal sepsis	2
[illegible]	8	Hysteria	[illegible]
[illegible]	8	Hematuria	2
[illegible]	7	Fibroids of the uterus	2
[illegible]	6	Acute bronchitis	2
[illegible]	6	Influenza	2
[illegible]	4	Papilloma of the bladder	1
Abdominal tumor	4	Retroflexion	1
Pleurisy	3	Perinephritic abscess	1
Renal tuberculosis	3	Malaria	1
Abortion	3	Postoperative sepsis	1
Lacerated perineum	2	Postoperative adhesions	1
Sciatica	2	Suspected meningitis	1
Cholecystitis	2		

Locally the pelves and calices of the infected kidney or kidneys were treated by irrigation with from 1 to 3 per cent. silver nitrate every fifth day, a culture being taken just before each lavage. The number of irrigations varied from one to twelve to secure the desired results; the majority of patients, however, required from three to five irrigations, 83 per cent. of our cures receiving a number within these limits.

There are very definite reasons for our percentage of cures being relatively so low. Since most of the patients were charity cases in a county institution, the relief of symptoms, to them, is synonymous with a cure, and they therefore discontinue treatment too soon. Some refused further treatment on account of the colicky pains sometimes produced by ureteral catheterization.

The fact that relief of symptoms does not always denote a cure has been demonstrated to us many times by patients who, having left the hospital symptomless but with urines positive for the infecting organism, return within the year following with the same or similar symptoms, and with the bacterial findings found on the first examination. They have had no symptoms from one to several months following their first symptomatic relief. It is logical to assume that during the symptomless period the infection, though still present, was inactive. These patients may justly be considered carriers in the sense that they have infectious foci, potentially dangerous to themselves. In such cases any factor that tends to reduce general or local resistance permits increased bacterial activity manifested by symptoms. It is important, therefore, to insist on treatment until all infection is eradicated. To be practically certain that such a condition is present, we believe that two sterile urines from ureteral catheters one week apart suffice, since there have been no recurrences in the patients so handled thus far, and some have been discharged for over a year. Patients are often examined whose urines are sterile for a period of one week, but yield a positive culture the week following from one or both kidneys. When the urine, however, remains sterile for two successive weeks, the kidneys are likely to be entirely free from bacteria.

The determination of cure in these cases is not altogether unlike that required for the cure of the carrier state in cases of typhoid fever, wherein it is believed that two successive negative cultures from stool and urine is sufficient to indicate that the individual is free from typhoid bacilli. One of the patients of our series had been a urinary typhoid carrier since an attack of typhoid six months before. Her focus was found to be in the pelvis of the right kidney, which disappeared at once with three pelvic irrigations. She had been under observation and medical treatment for six months previously, with no apparent change in her carrier state. She has remained bacilli free for the last four months.

It is a well known fact that passage of a ureteral catheter will in some instances produce a marked alleviation or complete subsidence of symptoms. This observation has influenced some to believe that the entire benefit obtained after pelvic lavage is due to the drainage established by the ureteral catheter. Undoubtedly there are many patients whose symptoms have been produced almost entirely by inflammatory obstruction along the ureter, and it is not unusual under these conditions for the symptoms to be relieved by drainage established by the passage of a ureteral catheter. We cannot conclude, however, that the result is a bacteriologic cure, as numerous occasions have presented themselves to test this point bacteriologically, and invariably the patients relieved by the catheter still have infected urines after a complete disappearance of symptoms. The danger of forcing infectious material into the secreting papillae of the kidney, while anatomically possible under sufficient pressure, is highly improbable when lavage is carefully performed. Therefore it would seem wise to perform lavage on all occasions in which drainage by means of a ureteral catheter is indicated, thereby getting the advantages of both drainage and the beneficial local action of the medicament. Although the medicament does not come in contact with all of the infecting micro-organisms, its action on the inflammatory tissues undoubtedly increases the bactericidal activity of such tissue. The mechanical effect of irrigation may act beneficially in certain instances when suppuration is profuse.

It is now generally agreed that the coccus forms, especially the staphylococcus, have a tendency to infect the parenchymatous rather than the renal pelvic tissue. The infecting cocci and the resultant lesions are therefore usually somewhat distant from the renal pelvis and calices, and anatomically not accessible to renal pelvic medication; on the other hand, the colon group infections being of the pelvis, calices and the immediately adjacent parenchyma, should be the type more suitable for this method of treatment. This bacteriologic and pathologic observation is confirmed by our results in the treatment of these infections. Twenty-seven, or 90 per cent., of all our cures were in infections by the colon bacillus group, and only three, or 10 per cent., were coccus infections. Though many more patients were treated for colon bacillus infection than for coccus infection, the percentage of bacteriologic cures is markedly lower for the coccus infection than the bacillus infection. Five patients with staphylococcus infection were treated for months with the foregoing internal and local treatment, with only temporary or quantitative improvement bacteriologically.

MUMPS MENINGITIS

JULIUS KAUNITZ, M.D.
NEW YORK

The most frequent complication seen in mumps is orchitis. The rarer complications are meningitis, encephalitis, neuritis, ovaritis, endocarditis, arthritis, nephritis, mastitis and vulvovaginitis. The complications appear in most instances in from four to seven days.

The meningitis of mumps is very little known. There is mention of 150 cases, although I have not been able to find more than thirty described, most of them appearing in an article by Acker,[1] in which two of his own cases are reported. During some epidemics, there appear to be more meningeal complications than in others. As most patients recover after a few days' illness, it is very probable that the meningeal condition is lost sight of, particularly in the milder cases. This very likely accounts for the fact that so few cases are on record and that so little is known of this complication.

The pathology, as found in the necropsies compiled by Acker, is that of a serofibrinous meningitis, in some instances invading the brain tissue and the nerves at the base of the brain. The cytologic and chemical tests of the spinal fluid are typical of the inflammatory process in the meninges.

The symptoms and signs resemble those of the meningitis of tuberculosis. The course of the disease, however, is very different.

The diagnosis, as a rule, is not difficult. The coincidence or immediate precedence of mumps is, of course, suggestive. Other forms of meningitis, particularly the tuberculous and epidemic cerebrospinal forms, which often appear to be a primary meningitis, must be ruled out. In tuberculous meningitis, there is usually a history of decline in health preceding the initial headache and vomiting. The course of the disease is very gradual, reaching its height between the second and the third weeks. From the start, epidemic cerebrospinal meningitis is very acute, with high temperature. Mumps meningitis begins insidiously with constipation, headache and vomiting, and little or no fever throughout, the height of the disease being reached in from twenty-four to forty-eight hours, and the complication terminating in from four to seven days. In tuberculous meningitis the spinal fluid during the first forty-eight hours shows no definite changes. In epidemic cerebrospinal meningitis, the spinal fluid is cloudy, and contains the characteristic organisms and many polymorphonuclear cells. In mumps there are many mononuclear cells in a clear or opalescent fluid. The diagnosis may be difficult when the complication appears late, after a mild case of parotitis.

Most patients recover, though in some instances, temporary neuritis has occurred. Atrophy of the auditory and optic nerves, also hemiplegia, is a feature of the cases. The gravest forms are those affecting the vital centers. If the substance of the medulla, as in poliencephalitis, or the vagus nerves are affected, the cases are sure to be fatal. A better prognosis can be promised those patients in whom the affection of the vital centers is only one of intradural pressure. Here a lumbar puncture, as in one of my cases, may be the means of saving the patient's life.

The following cases occurred in private practice during the months of February and March, when the epidemic of mumps was at its height. They illustrate some of the severer and milder forms one is apt to encounter.

REPORT OF CASES

Case 1.—G. F., a boy aged 4 years, was bright but undersized, and his parents were neurotic. At birth, the delivery had been made with the aid of instruments. He had been bottle fed from the second month. Two years previous to the time of consultation, he had had an attack of acute interstitial nephritis, complicating influenza. This condition of the kidney had persisted; otherwise the boy had been in apparently good health. Feb. 4, 1918, an acute epidemic parotitis on the right side developed. The temperature was 99 F. The right parotid remained slightly enlarged for two days, when the left began to enlarge. Neither side became unusually large, nor was the temperature ever more than 99.

February 18, at 10 a. m., the patient was sitting up in bed. There had been obstinate constipation, headache and vomiting for the past twenty-four hours. The temperature, pulse and respiration were normal. The left parotid was slightly enlarged. The abdomen was slightly retracted, but there was no rigidity of the neck or other meningeal sign. As the child had nephritis, the symptoms were attributed to this, and treatment was instituted accordingly.

February 18, at 5 p. m., there were intense headache, irritability and drowsiness. The child was on his back with the head held rigidly backward and the knees flexed. Both Kernig signs were present, together with a scaphoid abdomen and a tympanitic skull. The temperature was 97, the pulse 70, and the respiration 18. Vigorous catharsis and high enemas had been ineffectual.

February 18, at 10 p. m., I heard the typical cerebral cry in the street before I entered the house. The patient was now in a very bad state, with symptoms of intradural pressure. Reaction to all forms of stimulation was very sluggish. The pupils were dilated, showing no reaction to light. The Kernig and Babinski signs were very weak. The temperature was 96 and the pulse 54, being irregular and intermittent. The respiration was 12, and was of the Cheyne-Stokes variety. A lumbar puncture was done, and 20 c.c. of opalescent fluid were withdrawn under considerable pressure. Ten minutes later, the temperature was 97.8, the pulse 88, and the respiration 18. Two hours later the patient was sleeping restfully.

February 19, at 8 a. m., the patient was sitting up in bed demanding food. He complained slightly of headaches. Aside from a slight retraction of the abdomen and weak

---

[1] Acker, G. N.: Parotitis Complicated with Meningitis, Am. Jour. Dis. Child., December, 1913, p. 399.

Kernig sign, there were no signs of meningitis. There were, however, a slight erythema and a tache cérébrale, often seen in tuberculous meningitis, over the face and body. The bowels were open. From now on, for the next three days, there was a slight headache, some constipation and irregular pulse, after which the patient was in comparatively good health.

February 28, he experienced severe abdominal pain and vomiting. The temperature was 102, and the pulse 110, being irregular. The abdomen was very rigid and tender, as in peritonitis. These symptoms and signs persisted twenty hours, after which they subsided. The urine contained no sugar nor fat. There were no other metabolic changes present to confirm the suspicion of an acute pancreatitis. From now on the patient made an uneventful recovery. The report on the spinal fluid, made by Dr. Josephine B. Neal of the laboratory of the department of health of New York City, was: Ten c.c. opalescent fluid. Cytology, 99 per cent. Mononuclears, great increase. Bacteriology: Spread apparently negative. Culture, negative. Albumin + + 1. Globulin + + 1. Fehling's + + +.

Case 2.—H. S., a girl, aged 9 years, was bright, nervous and undersized. Her parents were of nervous temperament. She was fed by bottle from the first month. She had had measles three years previously.

February 24, she had a mild parotitis on the left side. The temperature was 101 F. The parotid gland was normal after two days. There was no fever after the second day.

February 28, intense prostration occurred with headache, vomiting and constipation of twelve hours' duration. There was a rigidity of the neck and spine, also a scaphoid abdomen and a slight Kernig sign. The temperature was 99, the pulse was 110 and irregular, and the respiration 20.

These symptoms and signs were present for the next four days, progressively improving. The gastro-intestinal symptoms disappeared first. The irregular pulse persisted for three weeks after the first appearance of the meningitis.

Case 3.—M. S., a girl aged 5 years, was bright and undersized. The parents were neurotic. She had been fed by bottle after the fourth month. She had had measles two years previous to the date of consultation, and lobar pneumonia with meningismus eight months previous.

March 5, 1918, a bilateral parotitis, moderately severe, appeared. The temperature was 102.

March 9, a severe headache set in, with vomiting and constipation, marked irritability and insomnia. The temperature, pulse and respiration were normal. The abdomen was retracted. There was a slight rigidity of the neck, with increased knee jerks, and a left Kernig sign was present.

The following day, the symptoms and signs were the same, but there was greater prostration. From now on, the patient progressively improved, except during a recurrence of the parotitis on both sides, March 11.

COMMENT

The last two cases were relatively mild and would ordinarily have passed as gastro-intestinal attacks. The absence of fever and the marked prostration should, however, make one suspicious. Meningeal irritation, or meningismus, is to be thought of in the milder cases even though the necropsies have demonstrated definite inflammation in the severer forms. In Case 1, there was no doubt of the diagnosis from the start, its course being very different from that of the other forms of meningitis. The value of early spinal puncture cannot be too much emphasized in this type of case. It was not indicated as a therapeutic measure in Cases 2 and 3, in which there were no signs of cerebral pressure.

165 Audubon Avenue.

Importance of Health.—With a greater degree of health among all, religion will become more effective for good, mortality will have a deeper significance and a wider application, and knowledge will multiply and distribute its blessings more widely.—Vaughan.

THE ANAMNESIS IN CARDIOVASCULAR DISEASE

WILLIAM BRADY, M.D.
ELMIRA, N. Y.

Cardiovascular disease is now the chief cause of death in the registration area, which covers slightly more than two thirds of the population of the United States. Cardiovascular degeneration, for the most part, is an insidious condition, far more difficult to diagnose in the incipient stages than is tuberculosis, but far more prevalent than tuberculosis and more frequently unrecognized by the practitioner.

As a result, I believe, of the great popularity of nostrums in this country, the millions in capital exploiting nostrums, and the vast propaganda of the nostrum interests that work indefatigably to misinform and mislead the lay public through every available avenue of publicity open to dishonest advertising, the great majority of victims of cardiovascular disease do not consult a physician until some alarming manifestation of the disease drives them to his office. And even then, too often, either the patient is averse to a painstaking examination or the physician is too busy, in his way, to make such an examination, so that the condition drifts on for months and years undiagnosed, nay, unsuspected, until disaster comes and realization bursts on the persons concerned. This is the explanation of the popular notion, a notion sometimes encouraged by physicians, that Bright's disease is generally fatal in a year or two, that apoplexy comes like lightning from a clear sky, that heart failure is a sudden calamity that occurs without warning. This is also the explanation for the shameful abuse of such makeshift terms as "debility," "overwork," "run down condition," "nervous exhaustion" and "neurasthenia" in lieu of a diagnosis of the cardiovascular degeneration of middle age.

It is a well recognized fact that a competent physician can and must make a tentative diagnosis of incipient pulmonary tuberculosis, and institute the proper regimen and treatment, long before bacilli can be recovered from the sputum and long before any serious breakdown of health has occurred. Granted that even the most skilful diagnostician occasionally errs in this tentative diagnosis, no great harm has been done the patient in any case, since the usual treatment employed for incipient tuberculosis can do no harm if the patient happens to have, say, masked exophthalmic goiter instead, and, indeed, may be precisely the treatment required by such disease. We all know that the best of diagnosticians is bound to make such mistakes; one with mediocre ability must confess such mistakes. But does this fact militate against the wisdom of a tentative diagnosis of tuberculosis? Or does it weaken the physician's morale in his procedure in future cases of similar character? Not if he is a good doctor. The only man who never makes a grave diagnostic error is the man who never makes a timely dignosis.

The average well trained physician nowadays has the ability to diagnose cardiovascular degeneration long before Bright's disease, heart muscle failure, apoplexy or general arteriosclerosis overtakes the patient. He has the necessary instruments of precision to corroborate his tentative opinion. But he lacks only the courage to be blunt. He fears to frighten his patient.

For years the same phobia handicapped good men in the diagnosis of incipient tuberculosis. It led them to rather sorry lengths. They fell into the bad habit of telling patients that there was "a weak spot" in one lung, "a slight catarrhal condition" in the apex, or "a few râles" audible by auscultation. They frightened the patient but withheld a definite opinion; in short, they quibbled. And quibbling only led to loss of confidence in the physician sooner or later.

Today we are passing through a similar era in our effort to grasp the tremendous problem of cardiovascular degeneration. We are quibbling with the patient. We are diagnosing "high blood pressure," "functional heart trouble" or "autointoxication." Patients with cardiovascular disease are drifting along from month to month, from year to year, in ignorance of their condition, and, what is worse, seeking relief wherever a plausible promise is held out — and plausibility is the hallmark of the modern charlatan.

What does a physician mean when he assures a patient the "trouble is only *functional?*" The truth is he does not exactly know what he means. He is quibbling with himself. Disease is altered function; if every organ is normal there will be no altered function. Then how can there be any distinction between "organic" and "functional" disease? Every organic disease is functional; if there were no functional disturbances there would be *no symptoms*. Every functional disease is organic, only our knowledge is sometimes not sufficient to make the diagnosis, or our opportunity is limited by circumstances beyond our control. The patient either will not submit to necessary observation and study, or cannot afford to pay for them.

The anamnesis of cardiovascular degeneration is written in the testimonials published by the nostrum makers, in the news columns of the daily papers, and in scattered, sketchy notes in the practitioner's case records. It is a puzzle picture so cut up and confused in medical textbooks that one succeeds in piecing it together into a significant whole only after some years of general practice. Perhaps the reason the picture is commonly overlooked is that it requires years to complete it in an individual case. And again, the patient is prone to lose interest in the effort and go off to sit for another artist. It is a new idea, this cardiovascular degeneration. The very term has an unpleasant sound. Degeneration, to the lay mind, suggests degenerate, and degenerate suggests something revolting. Deterioration is no better, for the victim in the last stage resents deteriorating. Had our friends the fishwives not already spoiled it, the change of life might meet the requirement; but one would be taking some risk telling a man that he was going through the change. General arteritis might suffice, unless some one has a more acceptable term.

Bearing in mind that cardiovascular degeneration is the most widespread disease of persons over 40 years of age and that it occurs probably ten times as frequently as cancer, one must think of it as a not improbable cause of the general ill health of patients of middle age who seek medical advice after a prolonged trial of the various nostrums and plausible remedies so popular with the public.

The man or woman of 40 or more who comes complaining of loss of strength, falling off in efficiency both physical and mental, gradual accumulation of superfluous weight, mild dyspnea on exertion, "stomach trouble" or "gas" not apparently due to abdominal lesion, restless or unrefreshing sleep, "all tired out," "run down condition," fatigue headaches, "poor circulation" or "nervousness" certainly requires a careful study of the cardiovascular system. A symptom that has struck me as rather suggestive in the anamnesis is failure of sexual competence in a middle-aged man not suffering with any discoverable genital lesion.

When repeated measurements at short intervals and at varying periods of the day show a constant elevation of the systolic pressure above 140 mm. of mercury, a diagnosis of cardiovascular disease should be considered feasible until definitely ruled out by rigid correction of the patient's habits.

Inability of the patient to hold the breath for at least thirty seconds without preliminary hyperpnea should raise the suspicion of cardiovascular disease.

A pulse rate remaining more rapid than normal for over three minutes after fifteen deep knee flexions should also arouse a suspicion of the cardiovascular integrity, be the patient a neurasthenic or not. "Neurasthenia" developing after 40 is in itself suggestive o cardiovascular degeneration, irrespective of alleged overwork or worry.

The full, florid or tumid face, with slight exophthalmos, in a person over 35 who has accumulated excessive weight in recent years and boasts of a hearty appetite, though troubled with "biliousness" or fulness after meals (a high stomach, some patients call it), is very likely a mark of cardiovascular disease.

It is the practice of physicians to treat acute respiratory infections, wrongly called "colds" and "grip," in a routine way, the expectant way, without attempting any great refinements of diagnosis. And this practice has proved reasonably satisfactory. But it has long been the practice to insist on great refinement of the diagnosis in cardiovascular disease, although the routine treatment that proves most successful is very much the same whether the individual case be considered *myocarditis, arteriosclerosis, nephritis* or *apoplexy*. Diet, medication, physical therapy, rest, exercise are all managed according to individual indications, and not according to the particular expression of the degeneration in a given instance. The administration of digitalis, for example, is not indicated by the expression of the degeneration, but by the patient's general condition as determined by examination. The same holds true of most remedial measures employed in cardiovascular disease. In other words, treatment cannot be intelligently prescribed for the disease, but must be suited to the needs of the patient.

Although the fine art of prognosis seems ever more difficult and unattainable in general practice, one harbors the idea that the best prognosis rests on an intimate knowledge of the patient's general condition rather than on any fine spun anatomic diagnosis of the specific area of his vascular system which is most injured.

In view of the common incidence of chronic cardiovascular degeneration as compared with that of tuberculosis, a diagnosis of the condition in its incipiency should be more frequently made than the diagnosis of incipient tuberculosis, and may be tentative as is that of the latter, with only benefit to the patient.

If physicians were in the habit of making such a diagnosis as a routine in daily practice, many millions of dollars now squandered by the laity for worthless and fraudulent nostrums and countless plausible brands of treatment exploited by irresponsible healers would probably be diverted to the useful work of preserving efficiency and prolonging life.

A PLAN OF RECTAL FEEDING

EDWARD E. CORNWALL, M.D.
BROOKLYN

In devising a plan of rectal feeding, it seems proper to take into consideration the following facts and principles.

Proof that the colon possesses adequate digestive capacity is lacking, and consequently all food introduced by way of the rectum should be completely predigested if it is not already in forms suitable for immediate absorption by the colonic mucosa.

It is necessary to think of the protein ration in terms of amino-acids, and of particular amino-acids, because the proteins of different foodstuffs split up into different groups of amino-acids, and the body not only requires for its synthetic purposes a definite variety of amino-acids, but requires them in particular proportions if its nitrogenous economy is to be favored. Articles of food whose protein contains potentially all the amino-acids that the body needs in approximately ideal proportions are animal flesh, eggs and milk. Flesh and eggs are undesirable because of their tendency to putrefy. Milk, while possessing all the advantages of flesh and eggs with some additional ones, is comparatively free from this disadvantage, being protected from putrefaction by its finely commingled lactacidifiable carbohydrate. Milk, then, appears to be the ideal source of protein for a nutritive enema. And it is obvious that the milk should be fresh and unboiled, so that its vitamins and enzymes may be preserved unchanged; and thoroughly peptonized and pancreatized, so that its protein may be reduced as far as possible to amino-acids. It should also be skimmed, because any considerable amount of fat introduced into the colon apparently cannot be of use and may be harmful.

Glucose in solution supplies carbohydrate in a perfectly available form.

Salts are as necessary in the diet as protein and fuel, and it is desirable that the salts ration be balanced. The salts of milk approximate the body requirements, and desirable salts may be supplied to a limited extent by strained fruit juices, which add, moreover, in the form of levulose, a carbohydrate that seems to be capable of absorption to a limited extent: the carbohydrate of milk, lactose, is apparently not available for fuel, but its susceptibility to lactic acid fermentation makes it useful for inhibiting putrefaction. Additional salts, particularly salts of sodium and calcium, are required if the rectal feeding is kept up for any length of time.

The essentially alkaline character of the diet should be preserved in a pronounced degree. This principle receives additional emphasis from the fact that the unavoidable insufficiency of the carbohydrate ration diminishes the capacity of the body to burn fats completely and increases the liability to acidosis. The human tissues in general require as a constant condition of their life that they be bathed in an alkaline fluid. This requirement would seem to be an inheritance from the primordial era when our remotest unicellular ancestors began life in the ocean. When in due time our ancestors emerged from the ocean to live on dry land, they dragged with them a bag of alkaline fluid not much dissimilar to sea water; and at the present time our body appears as a bag of such fluid with the tissues floating around in it. Oxidation is also a condition of life, and oxidation makes for acidosis. Acidosis constitutes as universal and constant a chemical menace to the life of our tissues as bacteria do a biologic one.

The vitamins, whose presence is necessary to enable the body to utilize its food, are apparently of two general classes, as regards certain physical characteristics, namely, the water soluble and the fat soluble. The former can be supplied by milk, cereal decoctions and fruit juices, and the latter by milk.

In accordance with these facts and principles, the following prescriptions for rectal feeding have been constructed.

PRESCRIPTION 1 FOR RECTAL FEEDING

This prescription supplies daily 20 gm. of protein, presumably in the form of amino-acids, fuel of the value of about 700 calories, salts and vitamins, and water to the amount of about 50 ounces.

At 6 a. m., a mixture, consisting of glucose, 1 ounce; strained juice of one-half orange; sodium bicarbonate, 30 grains; sodium chlorid, 30 grains, and water, to make 10 ounces, is injected.

At 8 a. m., 5 ounces of skimmed milk, thoroughly peptonized and pancreatized, are injected.

At 12 m., the same as at 8 a. m.

At 4 p. m., the same as at 6 a. m.

At 6 p. m., the same as at 8 a. m.

At 10 p. m., the same as at 6 a. m.

At midnight, the same as at 8 a. m.

Every second day, at 4 a. m., a colonic irrigation with physiologic sodium chlorid solution is given, and the glucose enema at 6 a. m. is omitted.

Modifications of Prescription 1.—The quantity of the glucose enemas may be reduced to 8 ounces.

The amount of the glucose in the glucose enemas may be reduced to one-half or two-thirds ounce.

The amount of the glucose enemas may be increased to 12 or 16 ounces with or without an increase in the percentage of glucose.

A quarter of an ounce of glucose may be added to each milk enema.

The glucose enemas may be omitted altogether, with or without substitution of drink enemas of physiologic sodium chlorid solution.

Calcium chlorid, 5 grains, may be added to each glucose or drink enema.

A culture of acidophilic bacteria may be added to any of the enemas as specified.

PRESCRIPTION 2 FOR RECTAL FEEDING

This prescription supplies daily fuel to the amount of about 700 calories, salts and vitamins, and water to the amount of 60 ounces, but no protein.

At 6 a. m., a mixture, consisting of glucose, 1 ounce; the strained juice of one-half orange; sodium bicarbonate, 30 grains; sodium chlorid, 30 grains, and water to make 10 ounces, is injected.

At 10 a. m., the same as at 6 a. m.

At 2 p. m., the same as at 6 a. m.

At 6 p. m., the same as at 6 a. m.

At 10 p. m., the same as at 6 a. m.

At 2 a. m., the same as at 6 a. m.

Modifications of Prescription 2.—The same modifications may be made of the enemas in this prescription as of the similar glucose enemas in Prescription 1.

The sodium bicarbonate in the enemas may be increased, even to 60 grains.

The orange juice may be temporarily omitted.

Calcium chlorid may be added to the enemas.

The enemas should be introduced at a temperature of 100 F., and slowly; the patient's buttocks s elevated, and he should lie on his right hour after the injections.

1218 Pacific Street.

THE SENSORY DISTRIBUTION OF THE TRIGEMINAL NERVE

WALTER MAX KRAUS, A.M., M.D.
Adjunct Assistant Neurologist, Bellevue Hospital
NEW YORK

The charts used to indicate the place, extent and nature of sensory changes due to disease of the nervous system fall into two groups: those showing the distribution of peripheral nerves, and those showing the distribution of the spinal segments or posterior roots. The distribution of the trigeminal nerve is sometimes included in both these groups. When it is, it is usually that of the entire nerve root (Fig. 2) or that of the three main branches entering the gasserian ganglion (Fig. 3).

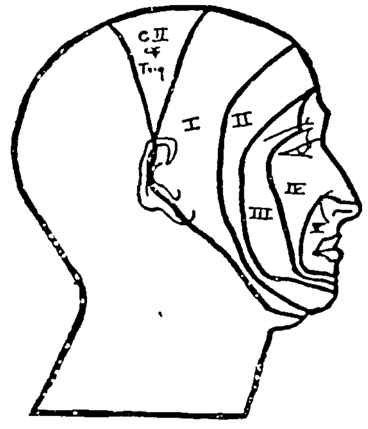

Fig. 1

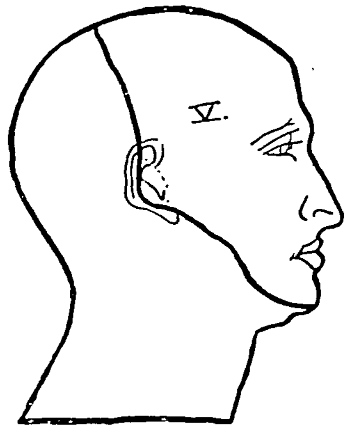

Fig. 2

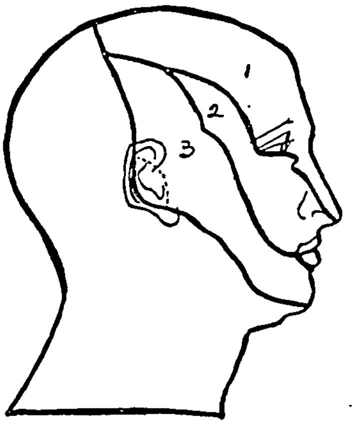

Fig. 3

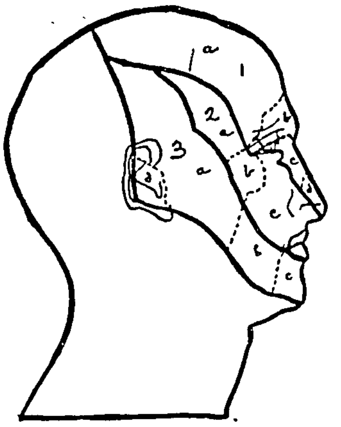

Fig. 4

Fig. 1.—Segmental distribution of trigeminal nerve, Section E (Dejerine). Fig. 2.—Radicular distribution of trigeminal nerve, Section C-D (Dejerine). Fig. 3.—Peripheral distribution of trigeminal nerve, Section B-C (Dejerine). Only the areas of the three main branches are shown. Fig. 4.—Peripheral distribution of trigeminal nerve, Section A-B, showing areas of branches of each of the three main branches: 1. *a*, supra-orbital; *b*, supratrochlear; *c*, infratrochlear; *d*, nasal; 2. *a*, temporal; *b*, malar; *c*, infra-orbital; 3. *a*, auriculotemporal; *b*, buccal; *c*, mental; *d*, gasserian ganglion. Composite of charts of C. L. Dana, Dejerine, Schäfer and Symington in Quain's Anatomy, and F. Merkel in Barker's Monographic Medicine.

The use of the word "segmental" is somewhat confusing. The terms "segmental" and "radicular" are often used interchangeably, and justly so when they apply to the spinal cord. This cannot be done in the case of the trigeminal, as will be shown presently. The word "segmental" should be limited to distributions of intramedullary origin.

Some confusion arises from the fact that the first two of the three distributions, segmental, radicular and peripheral, are identical for the spinal nerves. This is aggravated by the fact that no two of the three distributions is the same for the trigeminal nerves (Figs. 1-4). Figure 5 shows that the trigeminal nerve represents several sensory segments which supply sev-

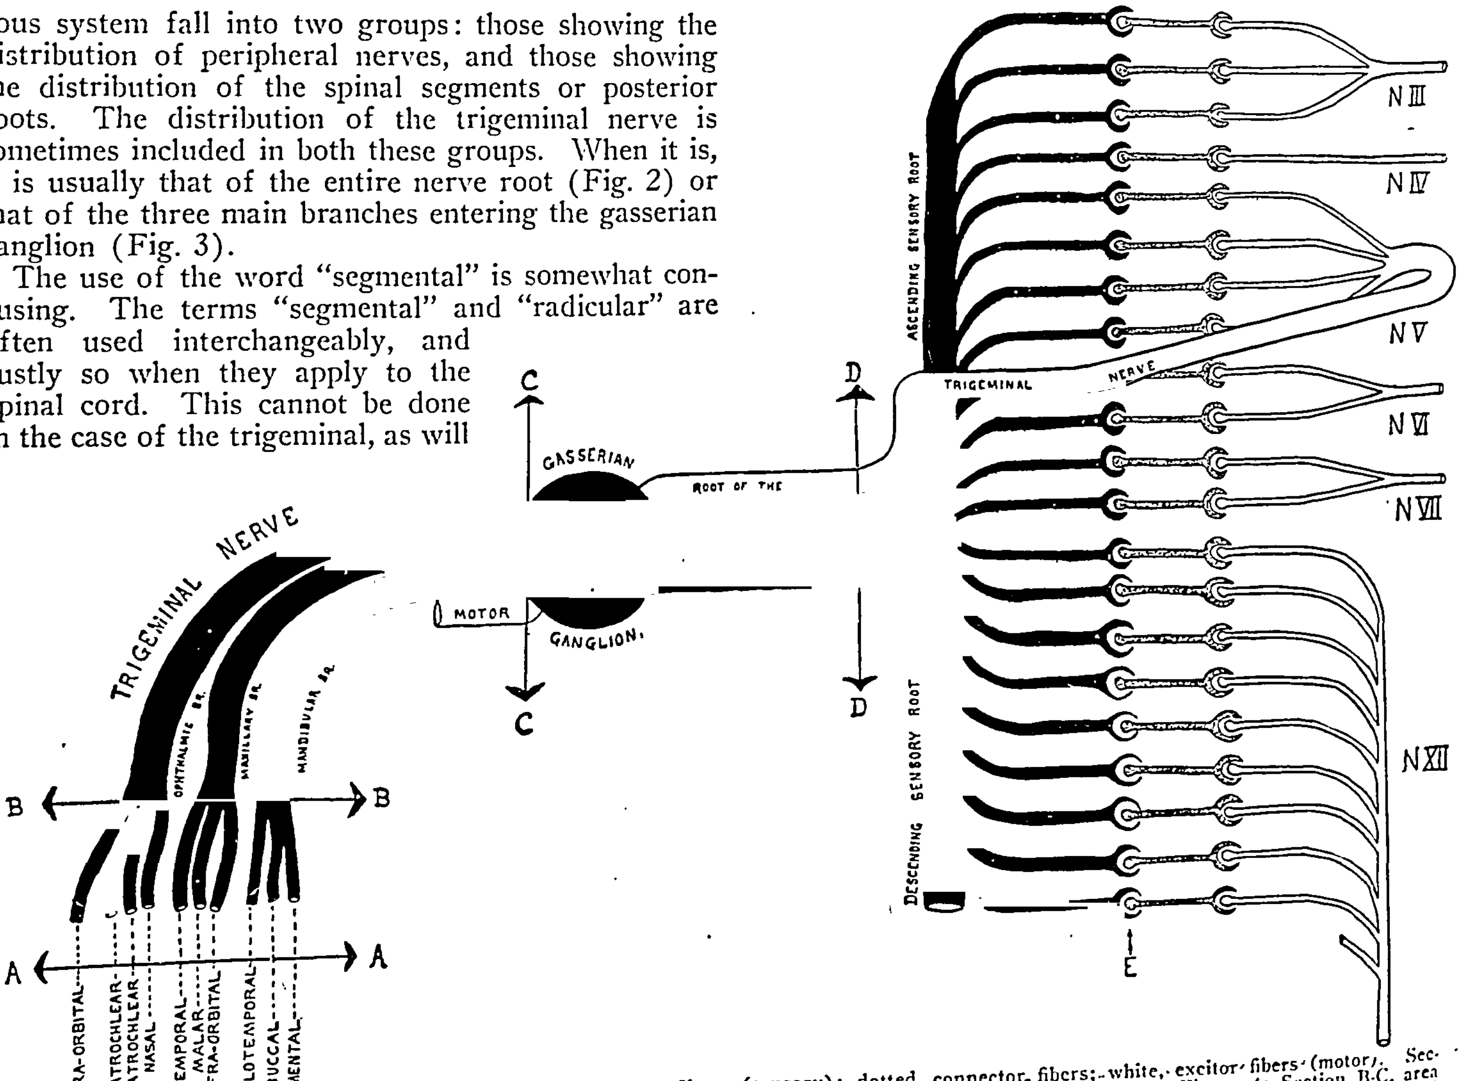

Fig. 5.—Black, receptor fibers (sensory); dotted, connector fibers; white, excitor fibers (motor). Section A-B, area of peripheral subdivisions; lesions give distribution shown on Figure 4; Section B-C, area of peripheral divisions; lesions give distribution shown on Figure 3; Section C-D, area of ganglion and root; lesions give distribution shown on Figure 2; Section D-E, area of ramification of root fibers; distribution of lesions not known with certainty; Section E, area of ganglion cells; place of juncture with fibers connecting to motor nerves and thalamic centers; lesions give distribution shown on Figure 1; lesions above E give distribution of area shown on Figure 2. Each ramification of the entering trigeminal root represents a primitive segment. In the case of the oculomotor roots, one segment has been omitted, in the case of the trigeminal, two, in order not to distort too greatly the relative length of the ascending and descending roots. The diagram is modified from Gaskell's Involuntary Nervous System, 1916, p. 6.

eral motor segments (the third, fourth, fifth, sixth, seventh and twelfth nerves). The diagram emphasizes the segmented nature of the trigeminal.

The inclusion of the radicular distribution of the trigeminal in a segmental chart omits the segmental (Fig. 1). The inclusion of the peripheral distribution (Figs. 3 and 4) is a mistake. The only proper area in a radicular chart would be the entire trigeminal area (Fig. 2). An examination of a number of textbooks on neurology has shown that the segmental distribution of the trigeminal (Fig. 1) is given only in Dejerine's "Séméiologie des affections du système nerveux" and White and Jelliffe's "Diseases of the Nervous System."

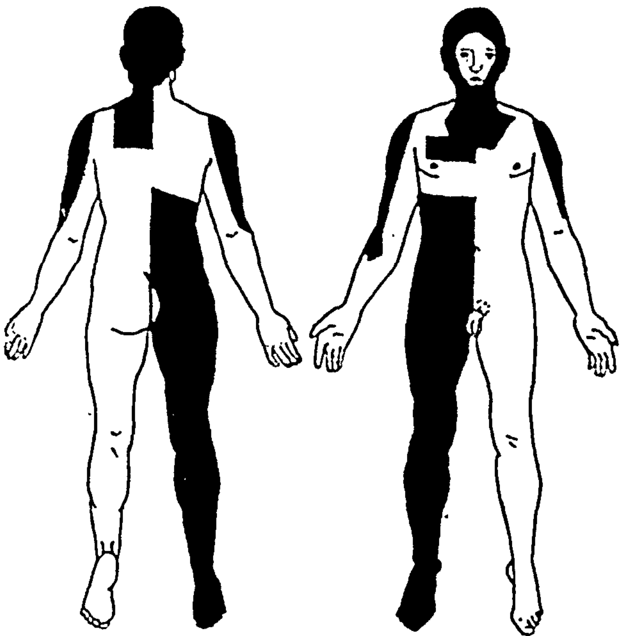

Fig. 6 (Case 1).—Areas of loss of pain sense. Note the helmet type of analgesia.

The somewhat complicated anatomy of the trigeminal as compared to that of a typical posterior root (Fig. 5) makes the question of the skin distribution of its sensory part equally complicated. Starting with the peripheral endings there are five different sensory distributions. The sections are divided as follows (Fig. 5):

Section A-B. Peripheral endings to the points of union of the branches of the three main divisions, ophthalmic, maxillary and mandibular (Fig. 4).

Section B-C. From the point of union of the branches of the three main divisions to the point of union of the three main branches themselves, that is, to the distal end of the gasserian ganglion (Fig. 3). Lesions of sections A-B and B-C give peripheral distributions.

Section C-D. From the distal end of the gasserian ganglion to the entrance of the nerve into the lateral aspect of the pons (Fig. 2). Lesions of this give radicular distribution.

Section D-E. From the point at which the fibers entering the pons begin to pass to the sensory intramedullary nucleus, to that nucleus itself. This nucleus extends from slightly above the level of the entrance of the nerve into the pons down to the third cervical segment (Fig. 5). It may readily be seen that a lesion involving the fibers just after their point of entrance into the pons will give a distribution like that prod by a lesion of Section C-D of the nerve. No diagram of the distribution which would be caused by a lesion of any part of Section D-E can be given, the reasons being that the description given by Dejerine (p. 836) is not clear to me, no diagram has been found illustrating this distribution, and no cases have been seen in which it has been made out.

Section E. This includes the ascending and descending nuclei and the fibers passing thence to the thalamus at their respective points of emergence from the nuclei. Lesions here give segmental distribution. The course of these fibers to the thalamus is known. They divide into two parts, a dorsal and a ventral. However, the function of the two parts has not been determined with certainty so that it would be impossible to give a chart of their distribution.

Two cases illustrating the segmental distribution are given to emphasize the necessity of having charts on which to indicate it. Only brief reports are given, as the object is only to emphasize the type of trigeminal distribution.

Case 1.—C. R., man, aged 47, Italian, hod carrier, single, had a queer feeling in the legs, an occasional burning in the right leg, weakness of the legs and the right hand, and pain in the lumbar region. He had had no illness of importance. Onset had occurred five years before, when he noted stiffness of the fourth and fifth fingers of the right hand. Two and a half years later he noted jumping of the left leg and a feeling of burning in the right leg. In the spring of 1917, weakness of the right hand began and also some difficulty in recognizing objects when grasped but not seen (astereognosis). He was unable when seen to feel cold water as such on the left leg. There was no bladder disturbance.

There were signs of involvement of the pyramidal tract, right and left. There was a right and left Babinski reflex, the knee jerks were exaggerated, and there was ankle and patellar clonus. The abdominal reflex was absent on the left. The reflexes of the upper extremity were present and equal.

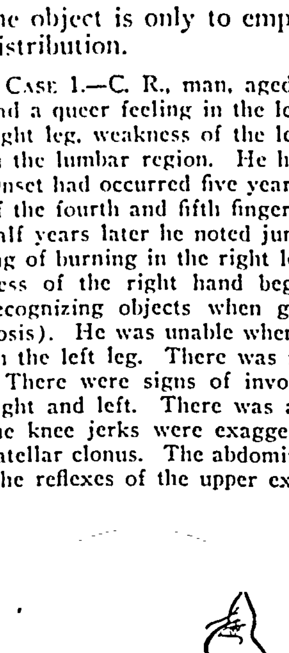

Fig. 7 (Case 1).—Areas of loss of pain sense.

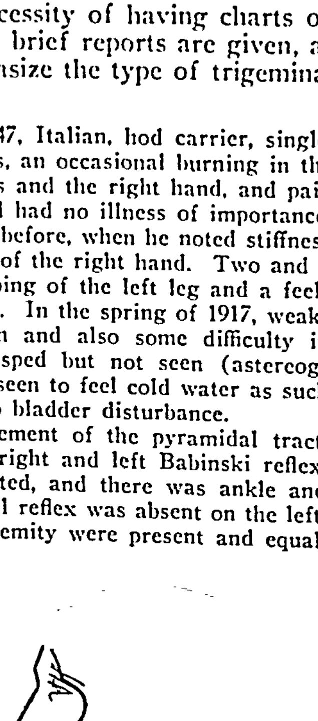

Fig. 8 (Case 1).—Areas of loss of pain sense.

There was fibrillary tremor of both deltoid muscles and the left quadriceps femoris. There was slight ataxia of the left hand (F-N test). Romberg's sign was absent. The sensation is shown in Figures 6, 7 and 8. Only pain and temperature were involved. Cerebral nerves other than the fifth were not involved.

The diagnosis was syringomyelia, syringobulbia.

Case 2.—G. W., woman, aged 65, married, hou plained of tingling and paresthesia of the a the left. There was muscular twitching of houlders. There was stiffness of the back constriction about the chest. There was difficulty in speaking and swallowing. Constipation was obstinate. The past history was negative. About twenty years before, the patient sustained a severe injury to the neck from a fall beneath a wagon. She was unconscious. She remained in bed seven or eight months because her back was weak. The left arm was paralyzed, but function was recovered about five weeks after the accident. The neck was weak and remained so for several years, there being difficulty in holding up the head. After a long period of practical freedom from any trouble, the following symptoms began to appear: difficulty in swallowing and talking, unsteady gait, and inability to use the left arm properly. These symptoms appeared about three years before the examination. There was also a feeling of constriction about the chest. All these symptoms have progressed slowly. At the time of the examination the patient was unable to lift her left arm; it felt weak and heavy. There had also developed a feeling of stiffness in the right arm. There had been obstinate constipation for three years. There was no history of bladder involvement. There was palpitation of the heart on the slightest exertion. She had also noted some unsteadiness and difficulty in walking. Four or five years before, the patient, after a violent sneeze, felt a snap in the neck and an electric shock down the left arm. She felt faint.

There was a horizontal nystagmus. The right pupil was greater than the left. Reaction was fairly prompt. As the result of an old accident, the patient could not count fingers with the left eye. She was hoarse. The reflexes were exaggerated at the knees and ankles. The Babinski reflex was elicited on both sides. There was no clonus. Hoffman's sign was observed in both hands. The right arm was freely movable. The left arm could not be raised. The biceps and triceps were powerless. Extension and flexion of the wrist was feeble. The trapezius and deltoid were almost powerless. The sternocleidomastoid was weaker than that on the right; the change, however, was slight. There was myokymia in both arms and shoulders, though mainly in the left. The left arm 50 cm. from the tip of the middle finger measured 1.5 cm. shorter than the right. The gait was slow and shuffling.

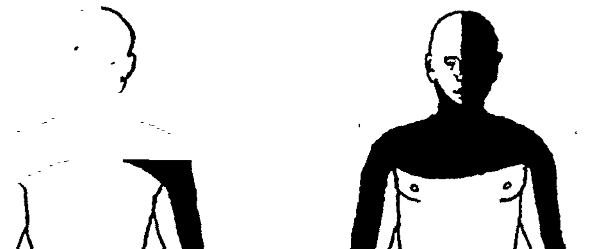

Fig. 9 (Case 2).—Areas of loss of pain sense, October, 1914.

There was no manual or pedal incoordination. There was slight postural difficulty in the thumb of the left hand. The sensation is charted in Figures 9, 10 and 11. Figure 9 shows the condition in October, 1914; there was involvement of the entire left side of the head. Figure 10 shows the condition two months later, and Figure 11 the condition two years after that. These charts are of pain sensation only. The changes of the extent of involvement of temperature sensation is not discussed, as this paper is meant only as a comment on types of trigeminal sensory distribution.

The diagnosis was syringomyelia and syringobulbia.

It will be seen that in Case 1, V-1 and V-2 are involved while the hypoglossal nucleus is not. This implies that the areas V-1 and V-2 are equivalent to the substantia gelatinosa Rolandi (sensory nucleus of the trigeminal) from the upper limit of the third cervical segment to about the level of the hypoglossal nucleus. Though we have no evidence like this to indicate that the place of transition between V-4 and V-5 corresponds to the plane of entrance of the nerve, the fact that there is a small part of the sensory nucleus running above this plane would make it probable. The area V-5 would in that case be supplied by that part of the nucleus lying above the plane of entrance of the nerve. As has been said above, we have no clinical evidence at hand to prove this.

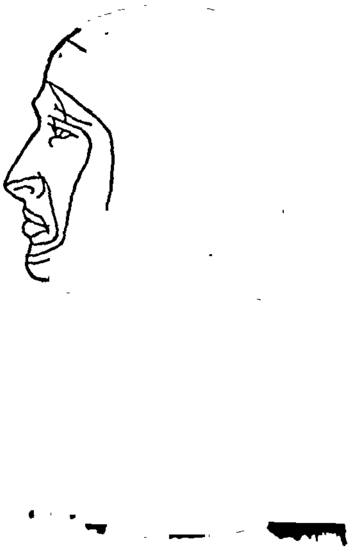

Fig. 10 (Case 2).—Areas of loss of pain sense, December, 1914. Note that the whole left trigeminal area was not involved at this time, as in October.

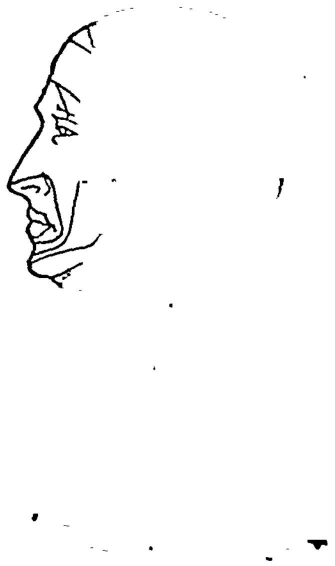

Fig. 11 (Case 2).—Areas of loss of pain sense, November, 1916. Note considerable changes in the contour.

It is suggested that charts showing cerebrospinal radicular distribution (Fig. 2) be eliminated. They are unnecessary because a cerebrospinal segmental chart will show the segmental distribution of the trigeminal (Fig. 1) and spinal nerves as well as the radicular distribution of the spinal nerves. On the other hand, a cerebrospinal peripheral chart will show the peripheral distribution of the trigeminal (Fig. 3) and spinal nerves as well as the radicular distribution of the trigeminal (Fig. 2, sum of the three divisions V-1, V-2 and V-3). Even greater usefulness could be obtained from the peripheral chart by giving the areas of the branches of the three divisions, V-1, V-2, V-3, marking the large divisions by a heavier line than that showing their subdivisions (Fig. 4). Thus this peripheral chart (Fig. 4) would show peripheral distribution of both divisions and subdivisions, while the segmental chart would show segmental distribution (Fig. 1), and they both would show the radicular distribution (Fig. 2, sum of V-I, V-II, V-III, V-IV and V-V in the segmental, sum of V-1, V-2 and V-3 in the peripheral). Either chart could be used for thalamic and suprathalamic distributions.

The Cost of Health.—We hear much of the high cost of living, but we overlook the fact that many of the best things of life can be had for nothing.—*Monthly Bulletin* (La.).

Clinical Notes, Suggestions, and New Instruments

A NEW BED DEVICE FOR FACILITATING THE DRAINAGE OF EMPYEMA THORACIS*

Irving R. Roth, M.D., New York

It is with the realization of the gravity of an improperly drained empyema and with the hope of facilitating such drainage, that I present this device.

It consists essentially of two parts: (1) an elevated canvas bed, spanned across the bed frame, with an opening in the canvas to permit the passage of a tube from the pleural cavity through it into the pus bottle below (Fig. 1), and (2) a series of air-tight bottles and tubes below the canvas bed (Fig. 2).

Bottle A (Fig. 3) is an 8-ounce, air-tight, pus bottle communicating with the tube in the pleural cavity. From Bottle A, air is exhausted by means of Bottle B, which is a 2-gallon irrigating bottle in which a vacuum is created by letting water flow out of its spout at the bottom by gravity into Bottle C, which is a 2-gallon plain bottle. When Bottle B is empty, it can again be refilled from Bottle C.

The patient is placed over the elevated canvas bed with the affected side dependent, with the tube from the chest through the opening in the canvas bed. This position favors a constant gravity drainage.

The system of tubes and bottles below the canvas bed, creating a vacuum in the pus bottle, tends to exhaust the pus from the pleural cavity, especially that which is not in direct line with gravity, or which, being too thick and tenacious, would tend to clog the drainage tube.

It would seem at first sight that other and better means of aspiration are available; but the one used in this device, which, with but slight modification, is the one previously used by Dr. Martin W. Ware of the attending staff at Mount Sinai, is perhaps the most useful. It is self-regulating in that, when the degree of vacuum in the pleural cavity is equal to that in Bottle B, the flow of the water from Bottle B to Bottle C stops. When the patient coughs or takes a deep breath, so that the pressure is again raised in the pleural cavity above that in the vacuum system in the bottles, the water begins to flow again automatically, and aspiration continues.

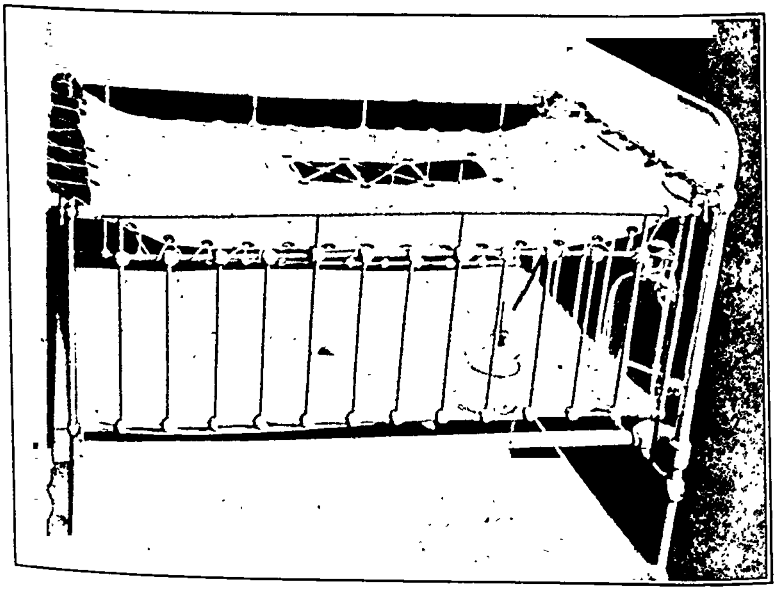

Fig. 1.—Bed device for facilitating the drainage of empyema thoracis.

At this point I would caution against the use of siphonage to create a vacuum in the pus bottle—as is often attempted—because a cough or deep breath, which in this method acts as an automatic start, would, in case of the use of simple siphonage, cause expulsion of the water from the siphon tubes and thus necessitate an attendant repeatedly to readjust the exhaust system.

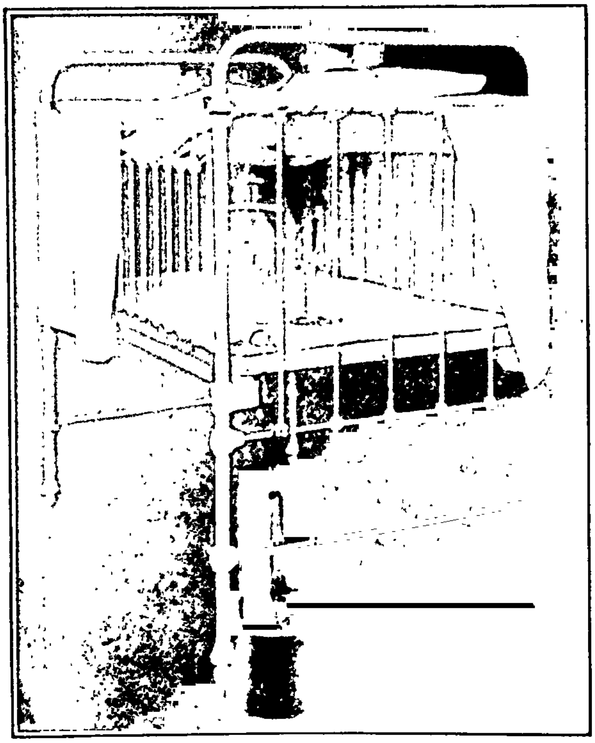

Fig. 2.—Arrangement of bottles and tubes.

ESSENTIALS TO THE PROPER USE OF THE DEVICE

1. The canvas bed should be sufficiently elevated to permit manipulation beneath it (from 16 to 20 inches).
2. The exhaust system should be air tight. Rubber stoppers should be used in all bottles.
3. The glass connecting tips should be of wide caliber throughout.
4. The drainage tube, which during operation is inserted to the depth of the pus cavity, should be withdrawn to about 1 inch from the opening in the chest, within from twenty-four to forty-eight hours after operation, so as to prevent accumulation of pus in the dependent portion of the pleural cavity around the base of the inserted tube.
5. The patient should be placed over the opening in the canvas bed, the affected side in the dependent position, with the tube from the chest pointing vertically downward in the direct line of gravity.
6. The drainage tube should be changed every three or four days in order to prevent plugging by tenacious pus or pieces of fibrin adhering to its lumen.
7. In order that the wound may be dressed, the tube leading from the chest to Bottle A is clamped, and disconnected at *D*. The tube leading from Bottle B to Bottle C is clamped. The patient is raised sufficiently to be in the prone position (Fig. 4). While the wound is being dressed the tube is secured to the chest wall by means of narrow strips of adhesive plaster, through a safety pin, which is passed through the wall of the tube, thus preventing the tube from slipping out of the chest.
8. In the case of children under 5 years of age, a binder may be placed across the chest and abdomen, reaching from the axillae to the umbilicus, secured by means of safety pins

---

* From the Surgical Division, Service of Dr. Howard Lilienthal, Mount Sinai Hospital.

to the canvas bed on each side in order to keep them in position. This should not be so tight as to immobilize the child.

9. After ten or twelve days, when only a small amount of serous fluid drains (from 2 to 4 drams in twenty-four hours), the child may be removed from the elevated bed, suction may be discontinued, and a small tube, cut down to the level of the chest wall, may be kept in the wound for three or four days to let the remaining pus drain into the dressing, after which the wound may be allowed to close.

10. Before the tube is finally removed from the chest, or if the temperature is oscillating, a roentgenogram should be taken to ascertain whether or not there is an encapsulated suppurating focus.

ADVANTAGES AS OBSERVED IN HOSPITAL WARDS

1. The constant gravity drainage with the intermittent self-regulating suction, besides emptying the chest in a short time, also removes subsequently formed pus as quickly as it forms, thus removing the irritating effect of retained pus from the pleural surfaces, so that, within from five to twelve days after operation, only a serous fluid is drained.

2. It prevents retention empyemas, thus incidentally preventing oscillating temperatures and toxicity from absorption; therefore, the appetite of the patient is good, and convalescence is rapid.

3. The partial vacuum created by the exhaust system tends to facilitate the early expansion of the impaired lung.

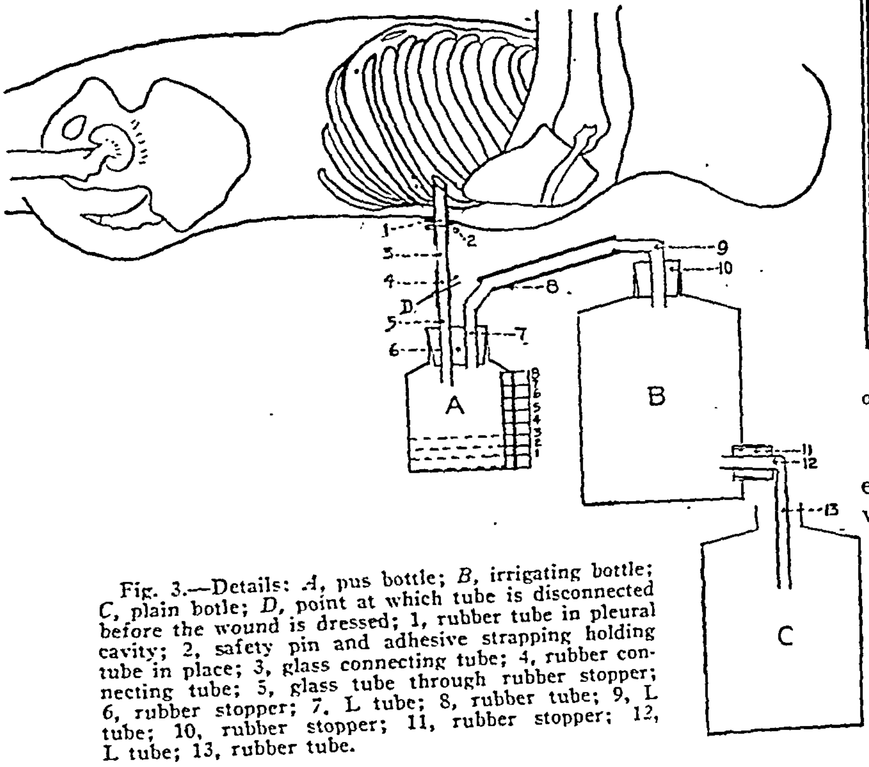

Fig. 3.—Details: *A*, pus bottle; *B*, irrigating bottle; *C*, plain botle; *D*, point at which tube is disconnected before the wound is dressed; 1, rubber tube in pleural cavity; 2, safety pin and adhesive strapping holding tube in place; 3, glass connecting tube; 4, rubber connecting tube; 5, glass tube through rubber stopper; 6, rubber stopper; 7. L tube; 8, rubber tube; 9, L tube; 10, rubber stopper; 11, rubber stopper; 12, L tube; 13, rubber tube.

Fig. 4.—Patient in position for dressing of wound.

4. Lying on the affected side facilitates the emptying of the pus cavity and removes the weight of fluid, which would press on and impede the function of the sound and compensating lung on the unaffected side.

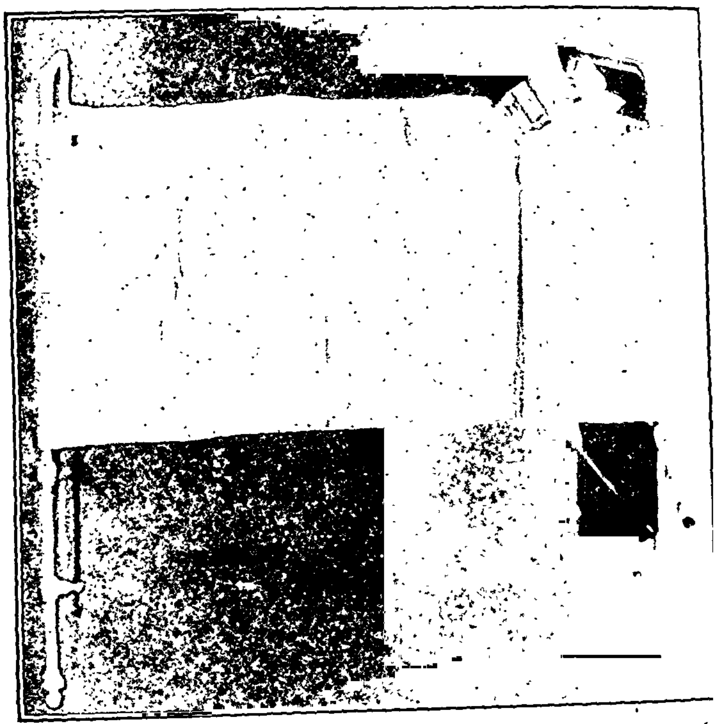

Fig. 5.—Empyema bed as it appears in hospital wards, draped, i order to prevent strong currents of air reaching patient from beneath

5. Pus does not drain into the dressings, whereby th excoriation of the skin from pus-sodden dressings is prevented.

6. Minor thoracotomy usually suffices, because of ampl subsequent drainage.

7. The amount of drainage as well as the character c the pus can be ascertained at a glance by aid of a transparent and graduated pus bottle (Fig. 3).

8. The device is simple in construction, sanitary, comfortable, well ventilated, applicable to any hospital bedstead, and applicable to a child of any age.

This method of draining empyemas has been in use a the Mount Sinai Hospital since August, 1917, and has give a uniformly gratifying result. The number of cases, as we as the details as to the influence of this method of drainage on them, will be reported at a future date.

THE PERONEAL TENDON AS A TRANSPLANT *

M. S. Henderson, M.D., Rochester, Minn.

In certain injuries to the hand, the tendons may be divide The patient may not present himself for some months afte the injury, and the surgeon is then confronted with a grea gap to be bridged between the ends of the tendon. Fasci lata removed from the thigh has been used with some succes to make up this deficiency. Occasionally, the patellar liga ment is accidentally divided and there is lack of extensio power with the consequent "flop" knee.

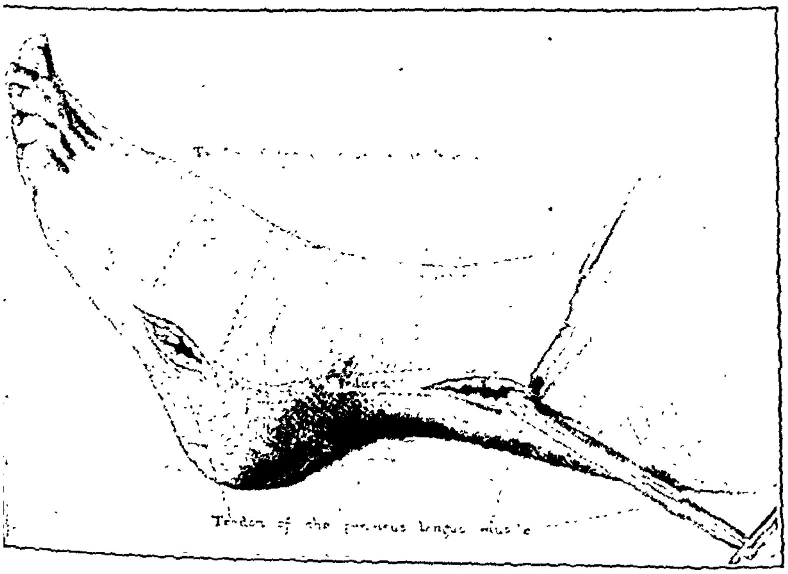
In two cases, one in which the hand was involved, and th other the knee, we removed a large piece of the perone longus and used it as a free transplant. In the knee th result was all that could be desired; the operation on th hand is too recent to justify the drawing of conclusions however, the wound healed by first intention. I have n seen in the literature any reference to the use of the perone tendon as a free transplant, and, even though it may hav been used, because of the general lack of knowledge concern ing it, the method is herewith reported. The tendon has a advantage for transplantation over the fascia lata, in that it is a true tendon ready to take on function as soon as nourished in its new home. The removal of the tendon causes no inconvenience to the patient, and it is possible that full regeneration takes place.

---

* From the Mayo Clinic.

About seven years ago I had an opportunity to observe the work of Sir Robert Jones, and since then I have operated in many cases of rigid flatfoot according to his method, that is, removing an inch or more of the peroneal tendons. No bad results or failure of regeneration of the tendons have followed. When a piece of the peroneus longus is removed, the peroneus brevis remains and is ample for function even if the peroneus longus does not regenerate.

After the field where the tendon is to be used is prepared (the leg having been prepared previously), the knee is flexed and the leg is rotated inward. Two small incisions are used. The lower incision is made below and a little in front of the external malleolus where the long peroneal tendon is divided just before it turns around the sole of the foot to be inserted into the head of the first metatarsal bone. The upper incision is made just behind the fibula, about 3 inches above the tip of the external malleolus, and the tendons are exposed. Pulling on the tendons above permits the peroneus longus to be readily identified; it is then divided below, and pulled up through the upper incision and divided there. In this manner, 5 or 6 inches of large tendon may be obtained and divided longitudinally into two or three pieces if so desired.



Method of removing peroneal tendon for transplantation.

THE PRACTICABILITY OF THE MODIFICATION OF THE LAVATORY CHAMBER

Zan D. Klopper, M.D., Chicago

One of the many causes of constipation is the faulty position the body assumes during the time of defecation.

To complete the act more successfully, it is desirable to bring the abdominal muscles into play, producing pressure on the colon and intestine, and forcing the fecal matter into the rectum. Such an accumulation may evacuate itself more forcibly, as a result of the bulk, and the stimulation of the rectal nerves governing the evacuation.

The majority of those persons whose occupations compel them to remain sitting the most of the day, as bookkeepers, coachmen, chauffeurs, various officials, students, many artisans, and also obese persons who take little or no exercise, find no difference between the seat ordinarily occupied during the day's activities, and the seat of the lavatory chamber.

Figure 1 shows the position of the body on the ordinary lavatory seat. While in this condition the abdominal viscera remain passive, and the abdominal muscles exert no more pressure than during any other activities while sitting. Furthermore, the lavatory seat, being comparatively comfortable, inclines one to reading, meditation or the planning of the day's work. After unsuccessful attempts, many persons will postpone the act for a more convenient time, thus neglecting to form the habit for every day at the same hour.

Figure 2 is a suggestion for a modification of the lavatory chamber. The horizontal seat is raised under the thighs, while a projected step assists in elevating the legs, thus bringing the thighs toward the abdomen, and compressing the rectus abdominis muscle anteroposteriorly. The body finds itself in such a position that the pressure from above by the diaphragm can be easily accomplished, and thereby the contents of the abdominal viscera are easily compressed downward.

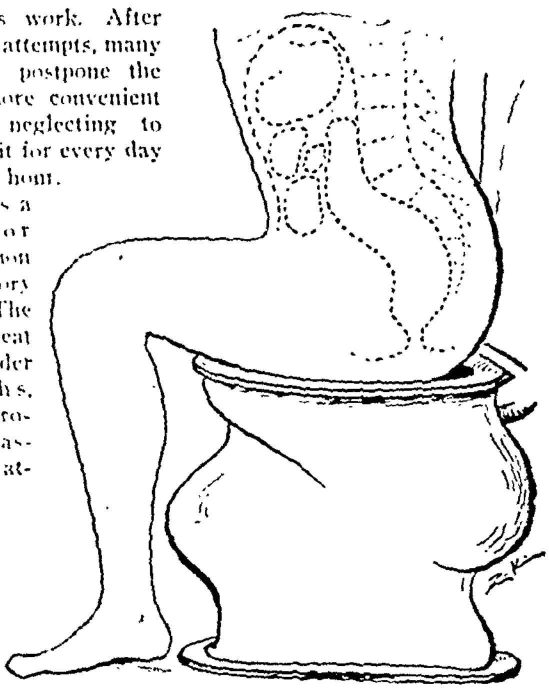


Fig. 1.—Position of the body on the ordinary lavatory seat.

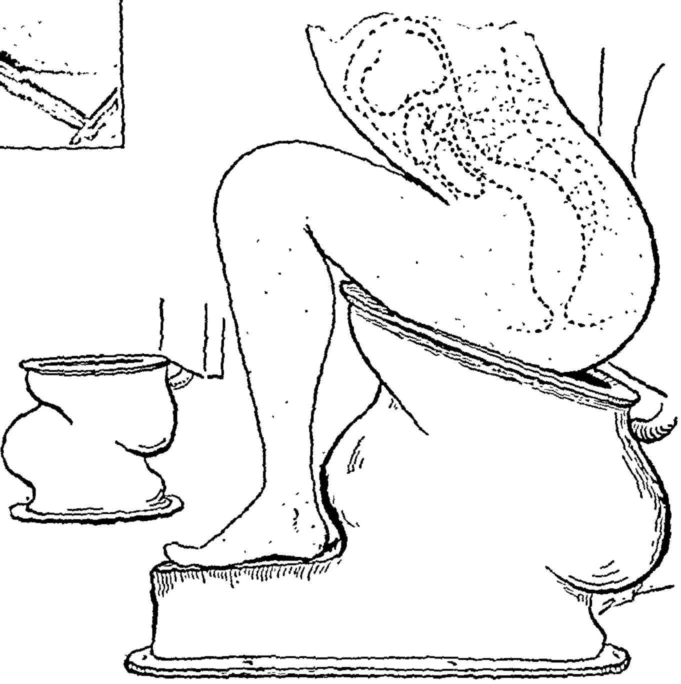

Fig. 2.—Position of the body on modified lavatory seat.

Military Medicine and Surgery

REPORT ON ARSPHENAMIN

SATISFACTORY USE OF THE ARSENOBENZOL BRAND IN ONE THOUSAND, ONE HUNDRED AND FOUR INJECTIONS FOR SYPHILIS

VICTOR N. MEDDIS, M.D. (Louisville, Ky.)
Captain, M. R. C., U. S. Army
AND
WILLIAM C. STIRLING, Jr., M.D. (Newark, N. J.)
Lieutenant, M. R. C., U. S. Army
CAMP ZACHARY TAYLOR, LOUISVILLE, KY.

The product introduced as salvarsan became scarce or unobtainable with the beginning of the European war. Under an act of Congress, a number of firms have been licensed to manufacture this product under the name arsphenamin. This American-made product, arsphenamin, is essentially identical with the product formerly sold as salvarsan.

At the base hospital, Camp Zachary Taylor, Ky., in a series of 1,104 injections of four different preparations, namely salvarsan (Farbwerke-Hoechst Company) of which we gave eighty-five injections, arsenobenzol, 1,011 injections, arseminol, twenty injections, and arsamin, eight injections, the results were the same in each preparation, salvarsan being slightly more soluble than the other preparations.

The method of preparing the solution as used here is as follows: A flask with a capacity of 500 c.c. is used in which to make the solution. Into this is poured 150 c.c. of freshly distilled sterile water with a temperature of about 95 C., and then ten ampules of arsphenamin are added. The solution is vigorously shaken after the contents of each ampule are emptied into the flask, until all the particles are dissolved. The solution is next rendered slightly alkaline by the addition of freshly prepared 15 per cent. sodium hydroxid solution. This at first forms a heavy flocculent precipitate which redissolves on the addition of more sodium hydroxid, and becomes clear. It is tested with litmus paper for final alkalinity, and after being filtered, it is ready for injection. We started by using 100 c.c. of water to each 0.6 gm., but gradually reduced the quantity of water until now it is being given in 30 c.c. of water. In no case were any ill effects seen from using this concentrated solution. The ordinary gravity method is the one employed, and a sufficient quantity for ten injections is prepared at one time. The median cephalic or basilic veins are the ones ordinarily selected, and with a 20 gage needle, 30 c.c. of the solution are allowed to run in, from eight to ten minutes being taken for the injection, the temperature meanwhile being kept at about 37 C. Ten minutes before receiving the injection the patient is given a hypodermic of 10 minims of a 1:1,000 solution of epinephrin subcutaneously to prevent any marked reaction. The injection is given usually in the afternoon, as less time is thus lost from duty. A purgative is given the night before, the noonday meal is omitted, and after receiving the injection the patient is required to remain quiet for the rest of the day.

From a therapeutic standpoint as good results were obtained with the arsenobenzol brand of arsphenamin as with the salvarsan brand. As a majority of the cases of syphilis were seen in the early secondary stage with initial chancre, macular eruption on the body or mucous syphilids in the mouth, we were able to begin treatment early and found that it required from three to four injections given every seven days to render the patient free from all active lesions. A dark field illumination test was made in all cases presenting suspicious ulcers, whether genital or extragenital, and blood was taken for a Wassermann test in every case. As soon as a man was free from all active lesions he was returned to duty with instructions to report back twice weekly for treatment. A course of treatment ordinarily consisted of eight intravenous injections of arsphenamin and a corresponding number of mercuric salicylate in 1 grain doses, given intramuscularly. These were repeated every seven days. The arsphenamin was usually given either on Monday or Tuesday, and the mercuric salicylate on Thursday or Friday. After receiving a full course of treatment, the patients were instructed to report for weekly inspection. If, at the end of a month, they presented no active symptoms, blood was again taken for a Wassermann test to determine what further treatment was necessary. Rarely in our experience has it required more than four injections to clear up all active lesions entirely, and in only three cases was it necessary to give more than the eight injections, before the first rest period.

Arsphenamin was given in several cases of phagedenic chancroid, that did not respond to other treatment. The improvement was rapid thereafter in all the cases. We regard all slow healing indolent ulcers as syphilitic, and they are treated as such even though the *Spirochaeta pallida* cannot be found in the lesion. As the majority of patients had received some form of local treatment, the presence of the spirochetes was, of course, hard to demonstrate. In some cases, in which the initial lesion did not show the organism, the enlarged inguinal glands were aspirated, a small hypodermic needle being used, and the gland being macerated to obtain some of the contents for examination. This causes very little pain and discomfort, and often the spirochete can be found in this way when it cannot be demonstrated in the initial lesion.

In this series of cases, only three extragenital chancres were seen, two being on the upper lip and one on the lower lip, and giving a history of no genital involvement.

In those cases in which the spirochetes were found in the initial lesion, treatment was begun immediately, and blood taken for a Wassermann test. It was rare for secondary manifestations to develop. In no case was arsphenamin contraindicated after careful examination was made of the heart and kidneys.

We are firmly convinced that the toxicity of arsphenamin is reduced to nil if proper precautions have been taken in preparing and giving the solution.

REPORT OF CASES

Two cases, selected at random, are herewith reported:

Case 1.—J. W. McL., aged 23, had had an initial lesion on the glans penis two years before, with a macular eruption on the body, and sore throat at that time. He maintained that a + + Wassermann test was made. He received one injection of neosalvarsan and took mercury pills for four months. He had no further trouble until about three months before when the right testicle began to enlarge, but was not painful and did not worry him unless he drilled hard. He was sent to the base hospital by the regimental surgeon. A Wassermann test was made. The right testicle was enlarged, hard, smooth and not painful. This was diagnosed as interstitial sclerosis and treatment was started. He was given eight injections of arsphenamin every seven days, and also mercuric salicylate. At the end of the fourth injection much improvement was noticed, the testicle becoming softer and much smaller in size. After receiving the eight injections, he was sent back to duty free from symptoms, with the testicle normal in size and the blood test negative. He was seen again at the end of one month, and two months, and was entirely free of symptoms.

Case 2.—A. G. D., aged 25, admitted to the hospital, Dec. 1, 1917, had had an ulcer on the glans penis eight months prior to entrance in the Army, and said he did not take any treatment and had no further symptoms until about five weeks before, when he noticed that he was becoming jaundiced. His skin was very yellow, he was easily exhausted on the slightest exertion, and he complained of severe headaches in the occipital region. On admission the patient was markedly jaundiced, the liver was enlarged and the stools were clay colored. The patient said he suffered from constipation. The Wassermann test was + + +. We began treatment, giving him one injection each week both of arsphenamin and mercuric salicylate. At the end of the course of eight injections his general appearance greatly improved, jaundice disappeared, and he returned to duty. At the end of a month and again at the end of two months he was still free from symptoms. The Wassermann test was negative.

Numerous cases could be cited to show the therapeutic value of arsphenamin, would space permit.

CONCLUSIONS

1. The arsenobenzol brand of arsphenamin made in this country is in our experience nontoxic, and equally as efficient therapeutically as the original Ehrlich preparation.
2. It may be used in concentrated solution with no ill effects.
3. Epinephrin, given in a 1 : 1,000 solution ten minutes before the injection, will control reaction.
4. The only reaction noted in this series of cases was slight headaches; in some cases, diarrhea and slight malaise were noted.
5. In phagedenic chancroids, "arsenobenzol" has a very beneficial effect, and is recommended where the healing is slow and response to other treatment is poor.

USE OF RABBITS AS SUBSTITUTE FOR WHITE MICE IN PNEUMOCOCCUS TYPE DIFFERENTIATION

HAROLD K. FABER, M.D. (San Francisco)
Captain, M. R. C., U. S. Army
CAMP LEWIS, AMERICAN LAKE, WASH.

In spite of the usefulness of Avery's rapid method for pneumococcus type differentiation, it is often desirable to resort to animal inoculation either for differentiation or for isolation of pneumococci.

The susceptibility of rabbits to pneumococcus infection is so well known that there may be some reason why they have not been generally used instead of white mice for pneumococcus type differentiation; but the reason is not clear, and no statements on this point have come to my attention.

Intraperitoneal inoculation of rabbits with pneumonic sputum has been carried out in fifteen instances, and in thirteen of these pneumococci were found in the heart's blood and peritoneal cavity in abundance, always with characteristic capsules. No other organisms were found by smear in the exudate, but in two instances in which the animals had been killed about twenty-four hours after inoculation a few colonies of other bacterial species were found in the culture. Pneumococcus in pure culture was in these cases recovered from the blood. In the two cases in which pneumococci were not recovered from the peritoneal cavity, the cultures and smears were negative, the Avery culture from the sputum was negative, and no pneumococci had been found in the sputum. It is assumed that the sputum was improperly collected.

The Rockefeller technic of preparation and injection of sputum was followed, except that about three times as much sputum was injected as is recommended for mice. Several of the rabbits died within twenty-four hours after inoculation. The others were killed from twenty-four to thirty-six hours after inoculation, and these yielded abundant exudate.

The age and size of the rabbits in the present small series seemed to have no influence on the severity of the infection, but this opinion may be modified by a longer experience. Rabbits as small as 600 gm., as large as 3,500 gm., and as young as 2 weeks were successfully inoculated.

It is not desired to express an opinion as to the relative merits of white mice and rabbits in this work. A substitute for mice was needed, and it was found possible to employ rabbits with satisfactory results.

New and Nonofficial Remedies

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application. W. A. Puckner, Secretary.

CHLORCOSANE.—A liquid, chlorinated paraffin containing its chlorine in stable (non-active) combination.

Actions, Uses, Dosage, Physical and Chemical Properties.—See The Journal, Feb. 16, 1918, p. 459.

Chlorcosane (Calco).—A brand of chlorcosane.

Chlorcosane (Calco) contains 31 to 35 per cent. of chlorine in stable (non-active) combination when assayed by the Carius method.

Manufactured by the Calco Chemical Company, Bound Brook, N. J. No U. S. patent or trademark.

Chlorcosane-Monsanto.—A brand of chlorcosane.

Chlorcosane-Monsanto contains 27 to 30 per cent. of chlorine in stable (non-active) combination when assayed by the following method:

Mix intimately 10 Gm. of sodium peroxide (Na_2O_2) and 1 Gm. of sodium nitrate ($NaNO_3$) and place about one-third of the mixture in a Parr bomb as used in sulphur determinations. Transfer 0.2 to 0.3 Gm. of *chlorcosane*, accurately weighed (from a narrow neck weighing bottle) into the bomb; cover the sample of chlorcosane with the remaining mixture of peroxide and nitrate. Close the bomb and screw down the cover tightly with the clamp. Heat the bomb rapidly to redness. The fusion is complete when a flash of flame is emitted from the small opening in the cover of the bomb. Cool by allowing tap water to flow over the bottom. Open the bomb and place it in a covered beaker containing 200 c.c. of hot water. After solution is complete, transfer the liquid to another beaker, returning the bomb in the first beaker, washing well with hot water and adding the wash waters to the first liquor. Add nitric acid until the solution reacts acid to litmus paper and heat to boiling. Cool and add an excess of tenth-normal silver nitrate solution; the excess is titrated with ammonium-sulpho-cyanide, ferric ammonium sulphate being used as indicator.

A blank test for chlorine is made on the reagent, using the same amounts and procedures but omitting the "*chlorcosane.*" Each Cc. tenth-normal [illegible] nitrate solution used equals 0.003546 Gm. chlorine. The chlorine [illegible] of chlorcosane should be not less than 27 per cent. nor [illegible] 30 per cent.

[illegible] Monsanto Chemical Works, St. Louis. No U. S. [illegible] or [illegible]

SURGEON-GENERAL GORGAS AND THE RESPONSIBILITY OF THE MEDICAL DEPARTMENT OF THE ARMY

No other branch of the Army is nearer the hearts of the people in time of war than the Medical Department. Fathers and mothers whose sons have enlisted may reconcile themselves if these sons are killed in battle; but if they have reason to fear that their sons have been neglected when sick or wounded, they develop a spirit of bitterness for which there can be no antidote. This natural attitude of mind is more or less apparent in all wars. A mother may bear with pride the news of the death of her son struck down in a charge or while stubbornly resisting an advancing foe; there is no consolation when she has reason to believe his death unnecessary, or that his health was not guarded by every known agency. If he dies from disease, as many soldiers must, she wishes to feel that kindness, intelligence and skill were at his service, and that the best of human effort was put forth in the endeavor to save him. If she realizes that he had every aid in his extremity that he could have enjoyed at home, she consoles herself, knowing full well that death must come to all.

While failure of the Medical Corps in the prosecution of war leads to grave disaffection at home, it has an even more serious effect on the morale of the Army itself. The soldier may bear great discomfort in his quarters or on the march—he may even court death on the battlefield—but he expects the best of care, sympathetic and kindly attention, and competent medical skill when he is sick or wounded. In this he is fully within his rights. When these helps fail, he becomes discouraged and even the ardor of patriotism fails to sustain him. Individually he becomes morose and complaining and in the mass inefficient. An army may be decimated by the missiles of the enemy and not only retain its courage, but become contemptuous of danger and death; when wasted by disease, however, or when its wounded soldiers are neglected on the field, it ceases to be an efficient fighting machine.

The disastrous effects of inadequate protection of the health and life of the soldier are not confined to disaffection at home and demoralization in the ranks; for disaffection and demoralization, even when moderately felt, lead to a great reduction in the fighting strength and the combative spirit. All nations engaged in this war realize the vital importance of the medical service and have provided liberally for its equipment, personnel and maintenance. In the European armies, those of our allies and those of our enemies, medical officers have been given higher rank, invested with more authority and held to greater responsibility than has been known at any time in the past. The medical service has responded most satisfactorily to these advancements in honor, trust and duty, and with the exception of the shameful failure of line officers to heed the reasonable requests of the Medical Corps in the Mesopotamian campaign, there has been no cause for complaint.

So far as we have advanced in this war, there is no ground for serious complaint of or by the medical service. The President of the United States has recommended advanced rank and authority for medical officers, and at the present writing it seems that both houses of Congress are in sympathy with this request. Appropriations have been liberal and, best of all, the Medical Department has so guarded the health of our soldiers that no army, even one-tenth the size of ours, has ever been mobilized with sickness and death rates so low. Indeed, so far as we know, no army of raw troops has been assembled with the death rate calculated for all ages as low as that of the civilian population from which the soldiers have been drawn. In this country this is about 14 per thousand annually. In the Spanish-American War the death rate from disease greatly exceeded this figure, and ran above 20 per thousand. During the six winter months of 1917-1918, the annual death rate among all soldiers in this country was 9.1 per thousand. In many camps the death rate has been lower than in the same age group in those sections of the country from which the troops have come.

◆

This, in brief, pictures the responsibility of the Medical Department of the Army. It is a responsibility which it gladly assumes. It may promise without a tinge of doubt that it will do its utmost to safeguard the morals, the health and the lives of our soldiers. As we write, there stands out the prominent fact that in this work the Medical Department has had as a leader a man who has the respect and confidence of all the American people and of all the scientists of the world.

The public, and the medical profession especially, are fortunate in having at the head of the Medical Department of the Army, in the present crisis, Surgeon-General Gorgas. General Gorgas, renowned for his successful combat with yellow fever, malaria and septic pneumonia on the Canal Zone, the work for which he has received the highest recognition among scientists and the people in general, has had a bigger problem among the troops of our country during the past winter and has achieved the same degree of success. His reputation will now include not only his remarkable record on the Canal Zone, in Havana and in South Africa, but also his efforts and the results in our camps during the past winter. He has commanded in our first great battle of this war, a battle in which more than a million men were engaged against dangerous diseases; and he has won a great victory.

Few men carry greater responsibilities than does General Gorgas. General Pershing in France must have more, and still more, soldiers. Every unfit man who reaches him is a burden, not a help, and not only fails to add to his fighting strength but lessens it. Moreover, even the fit who reach France must be kept fit, and this burden also lies on the shoulders of General Gorgas. Still further, he must care for the wounded, return to the fighting line those whom medical and surgical skill can speedily restore, and bring back home those more seriously injured and so rehabilitate them that they may return to civil life in the greatest possible comfort and with the least possible dependence on the assistance of others. His tasks are numerous and varied, but in the execution of them he may utilize his long experience and the wisdom it has given him. Moreover, his tasks will be performed with the most sincere sympathy for those involved. In the accomplishment of these duties every specialty in preventive and restorative medicine must be used. That General Gorgas has recognized this to the fullest extent is shown by his calling to his assistance many eminent men in every branch of the healing art. Indeed, he did not have to call, for they came and asked if they could render assistance. The readiness with which the very cream of our profession have left the comforts and attractions of their homes, disregarded their own financial and professional interests, shut their eyes to what it may cost them and their families, and offered their services, is due not only to patriotism, but also to their respect for, and admiration of, General Gorgas. They have rendered him the highest tribute that has ever come to a member of our profession. With General Gorgas at the head, the medical profession stands ready to fill the medical quota for any number of millions of men the President of the United States may call to arms.

THE WAR SESSION OF THE ASSOCIATION IN CHICAGO

Last week THE JOURNAL contained the preliminary programs of the Scientific Assembly of the American Medical Association and other information regarding the meeting to be held next month, June 10-14. A glance through the programs of any of the sections shows that the scientific work will be up to the usual standard and that, in most of the sections, papers and discussions on the relation of the medical profession to the war will be a prominent feature.

The OPENING MEETING, at the Auditorium Theater, Tuesday evening, will provide the keynote of the Session. In addition to the address of the President—Dr. Bevan—an address will be given by Governor Lowden of Illinois, whose patriotic addresses have been conspicuous for their fervor and for the enthusiasm they arouse.

A GENERAL MEETING, to be held Wednesday night at Medinah Temple, will be addressed by medical military representatives of the allied nations and by American medical officers who have seen service. The spirit of this meeting will be such as to stimulate enthusiasm, to knit in closer bonds the medical services of the allied armies and to develop a cooperative sympathy between the civilian physician and the medical officer.

The PATRIOTIC MEETING Thursday night at the Auditorium Theater will include addresses by Rt. Rev. Charles P. Anderson, Bishop, Diocese of Chicago, Episcopal Church, Judge Charles S. Cutting and Prof. John M. Coulter of the University of Chicago.

In addition to these general meetings and the Sections, three special day meetings of importance will be held: The first, under the chairmanship of Lieut.-Col. Frank Billings, head of the Division of Reconstruction and Rehabilitation of the Surgeon-General's Office, with Major James Bordley, Jr., as vice chairman, and Major Harry Mock as secretary, also of the Surgeon-General's Office, will be held in the Auditorium Theater Thursday and will be devoted to various phases of reconstruction, rehabilitation and reeducation of wounded soldiers. The speakers will be representatives of the Surgeon-General's Office and of the Red Cross. Some of the talks will be illustrated by moving pictures representing actual experiences in the great work of rehabilitation already being done abroad.

Another extremely important meeting will be that on the medical aspects of the selective service. This will be under the chairmanship of Major Hubert Work, medical aide in the office of the Provost-Marshal General, with the assistance of Major Reuben Peterson, vice chairman, and Major John M. Dodson, secretary, state aides to the governors of Michigan and Illinois, respectively. The Provost-Marshal General's Office will be represented by Lieut.-Col. J. Easby Smith and probably by other officers. This meeting will be of the greatest practical value at the present time to the physicians engaged on the boards working under the selective service law. When it is realized that there are some nine thousand physicians engaged in the work of the medical advisory boards and a like number in the work of the local and district boards, the need and the possibilities of this meeting for good may be better realized.

There is also under consideration a meeting on medical education, over which Major H. D. Arnold, who is in charge of this division of the Surgeon-General's Office, will preside. At this meeting will be considered problems of medical colleges and hospitals, medical students and interns in relation to the war. The time and places of the meetings on selective service and education will be announced next week.

MILK-BORNE INFECTION

In late years there has been a disposition in some quarters to question the importance of milk as a factor in spreading disease. Certain writers recognize the possibility of milk-borne infection, but consider it almost negligible from a practical standpoint. The latest report of the Massachusetts Department of Health, just issued, contains some interesting data on epidemics in that state during 1916. From the summaries it appears that among the outbreaks of communicable disease investigated, a number were traced to milk. Twenty outbreaks of diphtheria are summarized, one of these definitely traced to milk. A second "subepidemic" is also mentioned in connection with a small outbreak due to direct contact. Out of eighteen epidemics of scarlet fever, one was caused by milk. Seven outbreaks of typhoid fever are described, four of which, comprising nearly nine tenths of the cases, were due to milk. One outbreak of septic sore throat occurred during 1916. This also was connected with a milk supply.

It is evident from these brief epidemic histories, given in the Massachusetts report, that even after the great improvements that have been effected through inspection and pasteurization, milk is by no means to be ignored as a source of communicable disease. With respect to typhoid in Massachusetts, milk is still one of the chief vehicles of dissemination. This corresponds with what is known about the frequent occurrence of milk-borne typhoid in New York City in the past few years. The majority of outbreaks of scarlet fever and diphtheria are due, as they have always been, to contact infection; but the fact that milk is found to be a source of trouble in every considerable group of epidemics studied shows that we are far from being able to neglect this possible mode of transmission of these two diseases.

If such a condition obtains in the state of Massachusetts, where health administration is highly developed, and if at least 5 per cent. of the outbreaks of scarlet fever and diphtheria and a much larger proportion of those of typhoid fever can be traced definitely to milk, milk-borne infection cannot be dismissed from the attention of public health officials. Since there is reason to believe that a large proportion of the milk in Massachusetts is pasteurized, it is significant that, nevertheless, this important source of infection should still figure prominently in the reports of epidemiologists. We have still a right to be very much on our guard against the milk-borne infection of typhoid fever, septic sore throat, diphtheria and scarlet fever.

THE DIGESTIBILITY OF FISH

The necessity of restricting the use of meat in its various forms in practically all parts of the world now involved in warfare has directed attention more forcibly than ever before to fish as sources of human food. The response has been prompt. Long known species of fish have attained a sudden popularity, and new ones have been brought into dietary prominence. Furthermore, fish have been made available either in fresh or preserved form where they were formerly obtained with difficulty. Friday no longer offers the only opportunity to eat fish. Every day is fish day nowadays.

Although the reputation of fish, as a class, for suitability as a food has come to be fairly satisfactory, their use is not always free from misgivings on the part of the consumers or those who are responsible for the selection of dietaries. One source of this unfavorable tradition is found in the records of real or alleged cases of poisoning by fish. Of course, fish are particularly susceptible to bacterial decay, so that they deteriorate more readily than many other forms of animal food unless they are properly cared for. Fish frozen while fresh will keep for months and even a year without loss of essential good qualities or change of their sanitary characteristics. It is no just criticism of fish to say that they may be harmful unless they are preserved in perfect form. This essential applies to many other food products. The spoiling of an occasional can of salmon must not be allowed to bring ill repute to fish as a class; rather the industry responsible for objectionable products should be penalized.

Another criticism sometimes aimed at fish, namely, the imputation of a less satisfactory digestibility than applies to some other flesh foods, is now rarely heard. All justification for it seems to have been removed by various studies of the digestibility of fish, the most recent ones being recorded by Holmes[1] at the Office of Home Economics in the United States Department of Agriculture. Fish in the form of "fish loaf" was served as the major part of a simple mixed diet, which also included potatoes, crackers, fruit, sugar, and tea or coffee. On an average, the subjects ate 448 gm. (about 1 pound) of Boston mackerel, 471 gm. of butterfish, 440 gm. of grayfish, or 355 gm. of salmon daily, which would indicate that in every case the fish was eaten with relish. Of the results, the dietary expert of the department has this to say: The average coefficients of digestibility for fish protein were: Boston mackerel, 93.1 per cent.; butterfish, 91.9 per cent.; grayfish, 92.8 per cent., and salmon, 93.2 per cent. In view of the close agreement, it would seem, from a dietetic standpoint, that the different fishes studied would supply protein in equally available form. The average coefficients of digestibility of the fish fats were found to be as follows: Boston mackerel, 95.2 per cent.; butterfish, 86.4 per cent.; grayfish, 94.3 per cent., and salmon, 93.7 per cent. As these figures show, the fats were well assimilated in the case of the mackerel, grayfish and salmon, which, according to the usual custom, are to be regarded as "fat fishes." Considering the experiments as a whole, the very complete utilization of the protein and fat supplied by the fishes studied offers additional experimental evidence that fish is a valuable food and that its extensive use in the dietary is especially desirable.

In the prescription of fish in dietotherapy, the controlling factor of choice has usually been the fat content, which in turn has been assumed to determine the digestibility. Certain fish, such as cod and carp, are sometimes assumed to be "coarser" than others. The current statements, so far as they have any foundation, are presumably based on empiric observations. In order, however, to furnish at least some scientific background to his empiricism or hypotheses, it is well for the dietitian to have some clue to the essential facts of composition. Atwater, who collected data regarding fifty or more varieties, showed that, on an average, fish contain more than 18 per cent. of protein, and about 4 per cent. of fat. Generalizing from these data, it has been pointed out that fish may be divided on the basis of their fat content into three classes: those with more than 5 per cent. of fat, such as shad, salmon, butterfish and herring; those containing from 2 to 5 per cent. of fat, such as whitefish, halibut and porgy, and those containing less than 2 per cent. of fat, such as bluefish, haddock and cod.

Were it not for the confusion that still seems to prevail among many persons — even among physicians, in whom it is less excusable — regarding the position of fish in the classes of foods, it would seem ridiculous to make reference to the matter here. As Holmes has summarized the facts: It is evident that fish, like meat, may contribute materially to the fat of the diet, particularly if the fatter varieties are eaten. On the basis of the protein that they supply they also resemble meat, and this is true, too, with respect to the ways in which they are used in the diet. Accordingly, fish should be considered as a protein food and classed with the meats.

Current Comment

THE WORK OF THE AMERICAN RED CROSS

One hundred million dollars seems a big amount of money; to most of us it is a big amount. But when one hundred million dollars has to supply the needs of whole peoples, stricken and bleeding, and suffering continuously from new blows, it is not such a large amount after all. That at least seems clear from the financial statement of the Red Cross War Fund, March 1, 1918, just issued by the American Red Cross. The total receipts credited to the Red Cross War Fund to March 1, 1918, were $106,158,143.59. Of this amount, $16,881,424.26 was refunded to Chapters. Of the balance, $77,721,918.22 had been appropriated up to the date named above. The balance available for appropriation was but $11,554,801.11. Some idea of the number and distribution of the beneficiaries of money that has been spent can be gathered from the following synopsis of the geographical distribution of the principal appropriations for relief work:

France	$30,936,103.04
Belgium	2,086,131.00
Italy	3,588,826.00
Russia	1,243,845.07
Roumania	2,676,368.76
Serbia	875,180.76
Great Britain	1,885,750.75
Foreign Countries other than those named above	3,576,300.00
United States	8,589,899.27

The range of relief work has been great in variety as in territorial extent. From an appropriation for a special front-line "rolling canteen" service to provide hot drinks for the United States troops in the trenches, appropriations range to appropriations for the relief of children in Poland, $200,000; for the relief of Belgian children, $436,004; for condensed milk for Russian babies, $531,000; and appropriations of $1,000,000 for a model Red Cross Health Center, another of $1,140,129.70 for the care of needy children and the prevention of infant mortality, and a third one of $2,147,327 for the treatment and prevention of tuberculosis, all in France. The entire financial statement is set forth in considerable detail, with explanatory text, the whole making a pamphlet of 127 printed pages. The field covered, however, is so large that—

---

[1] Holmes, A. D.: Experiments on the Digestibility of Fish, Bull. 649, U. S. Dept. Agriculture, 1918.

the statement presents but a bird's-eye view. But out of it all stand two essential facts—that the work being done is vital to the support of the war and to the rehabilitation of the race, and that more money is needed to carry it on.

THE LIVER AND HIPPURIC ACID FORMATION

The formation of hippuric acid from benzoic acid and glycocoll in the body, a reaction of not inconsiderable significance in the genesis of a compound that vies with creatinin in being, next to urea, the most abundant nitrogenous component of the urine, is usually assigned to the kidney. The statements in regard to the place of origin of the hippuric acid are derived in the main from the classic experiments of Schmiedeberg and Bunge, and date back to 1876. The synthesis of the compound by the living cells, a striking phenomenon for that period, was demonstrated by perfusion of the kidneys of dogs. Among the evidences adduced more recently to indicate that such combinations as the production of benzoyl glycoll (hippuric acid) are by no means necessarily limited in the way once assumed are experiments from the Nelson Morris Institute in Chicago. Lackner, Levinson and Morse[1] studied the behavior of benzoates when dogs were poisoned with hydrazin sulphate, a substance that has been clearly found to produce extensive hepatic lesions while leaving the kidneys untouched. It appears that under these conditions the output of hippuric acid is lessened. Hence the inference is justified that the liver participates in the synthesis of this compound. The Chicago investigators suggest that it may become possible to gage the functional capacity of the liver by observations on the extent to which hippuric acid can be synthesized in selected persons. In view of the paucity of methods for detecting obscure hepatic disease, the suggestion may be worthy of further serious consideration and clinical investigation.

THE FORT RILEY BAND AT THE CHICAGO SESSION

A distinctive feature of the war session of the Association in Chicago will be the presence of the band from the Medical Officers' Training Camp at Fort Riley, Kansas. This is a band of forty pieces made up of enlisted men from the Medical Department. The Surgeon-General has granted his permission to the band to spend the entire week in Chicago, and it will be a prominent feature in all of the special meetings during the week.

SOME JOURNAL

The Chicago Number of The Journal—that for last week—was one of the largest issues, considering size and number of copies printed and circulated, that we have thus far issued. It required 86,560 pounds, or more than 43 tons, of paper.

Association News

THE CHICAGO SESSION

Entertainment for Visiting Medical Officers

The Chicago Medical Society has appointed a committee under the chairmanship of Dr. W. T. Mefford, to maintain headquarters at the La Salle Hotel for the entertainment of commissioned medical officers of the Army and Navy during the annual session of the American Medical Association, to be held in Chicago, June 10 to 14.

WAR CONFERENCE OF SECRETARIES OF THE CONSTITUENT STATE ASSOCIATIONS OF THE AMERICAN MEDICAL ASSOCIATION

Held at the Headquarters of the American Medical Association, April 30, 1918

(Concluded from page 1380)

OHIO

Dr. E. O. Smith, Cincinnati, said: I have but little to say for the state of Ohio. We have furnished our quota as far as we can learn and taking into consideration the number of physicians from Ohio who are in the National Guard service, those that are doing contract work, and those who are doing Red Cross work, we are considerably over our quota. We are told that our quota of this new call will be 350; the old quota was about 1,200, and I am sure our state will provide its quota, and whatever means you may adopt to get these men will be adopted by us. It is not so much the idea of getting 5,000 or 7,000 men. I think there will be little trouble in getting these men. There has not been a great deal of difficulty in getting the 18,000 or 20,000 men now in the service; but the things to be considered are those that have been mentioned by a number of the speakers, and among them adaptability of the individual to the service. We must consider also the nature of his work and his service at home in the community. Men from medical universities should not be allowed to volunteer, as many of them do; then the teaching forces would not be crippled. Ohio will furnish her quota, I am sure; and whatever plan is adopted, through our state association we can put into execution any sort of plan that is finally decided on.

I should like to ask that the privileges of the floor be granted to Dr. McClellan of Ohio, who has assisted in this work, and he will tell you something about the whole system.

Dr. B. R. McClellan, Xenia, said: In June of last year, Ohio stood low in the list of states in the proportion of men offered to the Medical Reserve Corps, and the Council of Defense selected two of us to go from county to county to arouse and appeal for volunteers. I should like to say a word in emphasis of what Dr. Smith has said as to the need in the future of some systematic way of selecting as well as allowing volunteers for Army work. The volunteer system is robbing communities, industrial centers and educational centers of some men that are absolutely needed; and whatever may have been conditions in the past, as we go on this way and the large number of physicians increase in the corps, it must come to pass that the interests of the communities and of the profession will suffer. Therefore, as much as I was opposed to selective conscription in the beginning, I heartily favor some systematic way of selecting men.

OKLAHOMA

Dr. Horace Reed, Oklahoma City, said: We organized in 1916 at the request of the Council of National Defense. The organization effected was strictly an organization of the state association plus a few members whom we got on the Council of National Defense. We proceeded to do what we could without having any definite plan or system in view to follow, but failed to get ourselves in line. Oklahoma is only about 10 years old as a state, and between the passage of the act creating the state and the constitutional convention several months intervened. There are half a dozen examining boards in the state in the different territories. You know the Oklahoma Territory, which was formerly the Indian Territory, was made up of seven districts. In one particular district it was advertised that any one who could furnish a voucher that he had been practicing medicine could go there and pay the sum of $50 and get a certificate to practice in Oklahoma. The consequence was that men came to Oklahoma by the hundreds and took advantage of that advertisement, and then an effort was made for the constitution to be retroactive and not pass a law which would undo that. We have a number of men credited in the list that could not be physicians and are not physicians. Another reason common to western states is that we have counties that are sparsely settled and physicians cannot be spared. Still another reason is that, in the beginning, this committee's work was largely in the hands of Dr. Clark, now Major Clark, who is in the service at Corpus Christi in a convalescent hospital. He was secretary of the Medical Association of the Southwest and volunteered to do the work in his office, and the committee was not conversant with the work. He elected Dr. Buxton as chairman of the committee. We are undertaking work which we believe will yield results. Dr. Buxton has sent out a questionnaire to one man in every community representing the county, usually the county secretary. This is done in cooperation with Dr. Thompson, secretary of the state association, and the committee. This questionnaire is to be mailed to every physician between the ages of 22 and 55 in Oklahoma, but it is unsigned.

---

[1] Lackner, E.; Levinson, A., and Morse, [illegible].: Aspects of Hippuric Acid Conjugation, Jour. Biol. Chem., 1918, 33, 1[illegible]

OREGON

Dr. Clarence J. McCusker, Portland, said: Our committees in Oregon are very much the same as those in many of the other states. The same confusion as to sending out a questionnaire occurs as in the questionnaires sent out by the government and the American Medical Association, and also one from the state society, which was furnished us by the Western Department of War at San Francisco. The one sent out by Colonel Lynch gave the best results, and those who said they would accept service were commissioned, some of them having been assigned to a base hospital, and they have made a trip over the state, and this has given the best results we have had so far. With this confusion of different agencies in asking for more men, I fear we are going to find it much harder to get the next 7,000 men than it was the first 7,000, and the next 7,000 will be still harder. We feel the need of a central agency and a classification of the men, so that we can put our finger on them and have the necessary authority to call on them when needed.

PENNSYLVANIA

Dr. Cyrus Lee Stevens, Athens, said: The question now is not what we have done, or what we have not done, but what are we going to do. I believe that each one and all of us propose to go over the top. My friend from Michigan (Dr. Warnshuis) did not exactly steal my thunder, but he used my ammunition, and did it so much more effectively than I could, that I will forgive him for it. As has been intimated by the chairman, our state has sent the second largest number of physicians. We are not planning to rest on anything we may have done, but are ready to take hold and continue our work and be loyal to our government, loyal to our profession and loyal to the organization, whether it be national, state or county.

What has been accomplished in our state is due to several things. I might mention some of them—organization and public professional spirit. All of our county societies have agreed to remit the dues of those who are in the service or in the service of any of our allies. The state society has remitted the per capita assessment of all such. Two of our county societies have insisted on paying the state society per capita assessment. Most of the county societies, not all of them, have promised to protect, so far as they can, the practice of those who have gone or who may go. This, of course, cannot be carried out without failures here and there, without imperfection and without possibly some friction, possibly some misunderstanding. Some have agreed to turn over as high as 60 per cent., some 50 per cent., some 40 per cent., and some 33.3 per cent., and this is being carried out as well as the circumstances of such a delicate thing will permit. This plan has its imperfections. THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION and our state journal have made constant appeals, which have gone a great way toward inducing physicians to make application to enter the Medical Reserve Corps. Another thing that has enabled us to do work has been the state committee of the Council of National Defense, Medical Section, which has done very thorough work in Pennsylvania, largely through the efforts of Dr. Codman and Major Jump and others. Like the rest, the department has made its mistakes, we have had more or less duplications, and we know more now than we did when we began: but the committee deserves credit for what has been accomplished. We know pretty well the standing of each man. We have found that some of our rural communities, and not a few of our industrial communities, are really suffering for the want of medical men, and these should be cared for in some way.

RHODE ISLAND

Dr. J. W. Leech, Providence, said: I do not believe there is a lack of patriotism on the part of the profession in our state, but rather in large part it is due to a failure of the government to take men into the service promptly after they receive their commissions. When a man gets a commission, puts his house in order, and is anxious to get into the service, if he has to wait six months it is discouraging to him, and this of itself cannot fail to be detrimental to eligible men who have not received a commission. In a community with a medical population of thirty-eight, eight have accepted commissions, and only four of them have been called to active service. The result is discouraging. I would be in favor of a selective draft to call for physicians at the age of 55 who are physically fit. This is the only efficient and democratic way of getting a full Medical Reserve Corps into the service.

SOUTH CAROLINA

Dr. Edgar A. Hines, Seneca, said: Our work in South Carolina thus far has been similar to that in many other states that have already reported. Much of the work has been done through the state committee of the Council of National Defense. I believe that the public speaking method and the questionnaire method, particularly the latter method, have resulted in as many men as we are going to get. Our state association had a military program in the last few days. We had a representative from the Surgeon-General's Office, and many of the points that we did not understand were cleared up by him. I believe that we are now ready for more intensive work, and I think that this must be personal work. I have doubt about the feasibility of a county committee in a state like ours. I believe that a central committee probably will do the best work. I am convinced that now it is personally a question of putting it up to each man.

TEXAS

Dr. I. C. Chase, Fort Worth, said: We have 278 counties in the state, many of which are officered only by physicians who are encouraged and induced to stay, not because of the prosperity but because of the needs of the ranch people; consequently many of them stay. It is safe to say, after carefully looking over the state, that only seventy counties in the state have a sufficient medical population to furnish doctors. For that reason, seventy of the 278 counties have to furnish the quota for the entire state. Major Jump, in a recent itinerary, after looking the matter over, thought we had done well. I am frank to say that we should not have done so well had it not been for the terrible drought throughout the state which drove many rural districts into a bread and butter situation. The general situation there has been handled in a rather disastrous manner, commencing with a canvass of the state by the committee on medical preparedness, officered by two commissioned officers who are placed at the head in turn of the State Council of National Defense for the collection of statistics, and in turn removed, so that in coming into affairs recently and looking the matter over, I found that one of the two things essential for success in the work, the first and most important part, has been neglected. For that reason, we are compelled to begin again and take a very careful survey of every physician in the seventy counties in the state. This has cost the last two times over a thousand dollars each, and will cost more than that and occupy probably sixty days. We have a committee of forty, each having two counties. We have a committee of five in each of the seventy counties, in all about 400 men, with an office force to handle the work. At the end of sixty days we hope to have detailed information as to the age, physical condition, wife and number of children, property and income, and the needs of the community, etc., to enable the committee thoroughly to canvass the state, and probably select a thousand men and then begin the pressure.

UTAH

Dr. W. Brown Ewing, Salt Lake City, said: We have had all the problems mentioned here. The first affliction wished on us was the State Council of Defense, which [illegible] ly died last week. Major Jump was around in [illegible] the embalming, and it has been buried since the statement presents but a bird's-eye view. But out of it all stand two essential facts—that the work being done is vital to the support of the war and to the rehabilitation of the race, and that more money is needed to carry it on.

THE LIVER AND HIPPURIC ACID FORMATION

The formation of hippuric acid from benzoic acid and glycocoll in the body, a reaction of not inconsiderable significance in the genesis of a compound that vies with creatinin in being, next to urea, the most nt nitrogenous component of the urine, is igned to the kidney. The statements in the place of origin of the hippuric acid ved in the main from the classic experiments f Schmiedeberg and Bunge, and date back to 1876. The synthesis of the compound by the living cells, a striking phenomenon for that period, was demonstrated by perfusion of the kidneys of dogs. Among the evidences adduced more recently to indicate that such combinations as the production of benzoyl glycoll (hippuric acid) are by no means necessarily limited in the way once assumed are experiments from the Nelson Morris Institute in Chicago. Lackner, Levinson and Morse[1] studied the behavior of benzoates when dogs were poisoned with hydrazin sulphate, a substance that has been clearly found to produce extensive hepatic lesions while leaving the kidneys untouched. It appears that under these conditions the output of hippuric acid is lessened. Hence the inference is justified that the liver participates in the synthesis of this compound. The Chicago investigators suggest that it may become possible to gage the functional capacity of the liver by observations on the extent to which hippuric acid can be synthesized in selected persons. In view of the paucity of methods for detecting obscure hepatic disease, the suggestion may be worthy of further serious consideration and clinical investigation.

THE FORT RILEY BAND AT THE CHICAGO SESSION

A distinctive feature of the war session of the Association in Chicago will be the presence of the band from the Medical Officers' Training Camp at Fort Riley, Kansas. This is a band of forty pieces made up of enlisted men from the Medical Department. The Surgeon-General has granted his permission to the band to spend the entire week in Chicago, and it will be a prominent feature in all of the special meetings during the week.

SOME JOURNAL

The Chicago Number of The Journal—that for last week—was one of the largest issues, considering size and number of copies printed and circulated, that we have thus far issued. It required 86,560 pounds, or more than 43 tons, of paper.

THE CHICAGO SESSION

Entertainment for Visiting Medical Officers

The Chicago Medical Society has appointed a committee under the chairmanship of Dr. W. T. Mefford, to maintain headquarters at the La Salle Hotel for the entertainment of commissioned medical officers of the Army and Navy during the annual session of the American Medical Association, to be held in Chicago, June 10 to 14.

WAR CONFERENCE OF SECRETARIES OF THE CONSTITUENT STATE ASSOCIATIONS OF THE AMERICAN MEDICAL ASSOCIATION

Held at the Headquarters of the American Medical Association, April 30, 1918

(Concluded from page 1360)

OHIO

Dr. E. O. Smith, Cincinnati, said: I have but little to say for the state of Ohio. We have furnished our quota as far as we can learn and taking into consideration the number of physicians from Ohio who are in the National Guard service, those that are doing contract work, and those who are doing Red Cross work, we are considerably over our quota. We are told that our quota of this new call will be 350; the old quota was about 1,200, and I am sure our state will provide its quota, and whatever means you may adopt to get these men will be adopted by us. It is not so much the idea of getting 5,000 or 7,000 men. I think there will be little trouble in getting these men. There has not been a great deal of difficulty in getting the 18,000 or 20,000 men now in the service; but the things to be considered are those that have been mentioned by a number of the speakers, and among them adaptability of the individual to the service. We must consider also the nature of his work and his service at home in the community. Men from medical universities should not be allowed to volunteer, as many of them do; then the teaching forces would not be crippled. Ohio will furnish her quota, I am sure; and whatever plan is adopted, through our state association we can put into execution any sort of plan that is finally decided on.

I should like to ask that the privileges of the floor be granted to Dr. McClellan of Ohio, who has assisted in this work, and he will tell you something about the whole system.

Dr. B. R. McClellan, Xenia, said: In June of last year, Ohio stood low in the list of states in the proportion of men offered to the Medical Reserve Corps, and the Council of Defense selected two of us to go from county to county to arouse and appeal for volunteers. I should like to say a word in emphasis of what Dr. Smith has said as to the need in the future of some systematic way of selecting as well as allowing volunteers for Army work. The volunteer system is robbing communities, industrial centers and educational centers of some men that are absolutely needed; and whatever may have been conditions in the past, as we go on this way and the large number of physicians increase in the corps, it must come to pass that the interests of the communities and of the profession will suffer. Therefore, as much as I was opposed to selective conscription in the beginning, I heartily favor some systematic way of selecting men.

OKLAHOMA

Dr. Horace Reed, Oklahoma City, said: We organized in 1916 at the request of the Council of National Defense. The organization effected was strictly an organization of the state association plus a few members whom we got on the Council of National Defense. We proceeded to do what we could without having any definite plan or system in view to follow, but failed to get ourselves in line. Oklahoma is only about 10 years old as a state, and between the passage of the act creating the state and the constitutional convention several months intervened. There are half a dozen examining boards in the state in the different territories. You know the Oklahoma Territory, which was formerly the Indian Territory, was made up of seven districts. In one particular district it was advertised that any one who could furnish a voucher that he had been practicing medicine could go there and pay the sum of $50 and get a certificate to practice in Oklahoma. The consequence was that men came to Oklahoma by the hundreds and took advantage of that advertisement, and then an effort was made for the constitution to be retroactive and not pass a law which would undo that. We have a number of men credited in the list that could not be physicians and are not physicians. Another reason common to western states is that we have counties that are sparsely settled and physicians cannot be spared. Still another reason is that, in the beginning, this committee's work was largely in the hands of Dr. Clark, now Major Clark, who is in the service at Corpus Christi in a convalescent hospital. He was secretary of the Medical Association of the Southwest and volunteered to do the work in his office, and the committee was not conversant with the work. He elected Dr. Buxton as chairman of the committee. We are undertaking work which we believe will yield results. Dr. Buxton has sent out a questionnaire to one man in every community representing the county, usually the county secretary. This is done in cooperation with Dr. Thompson, secretary of the state association, and the committee. This questionnaire is to be mailed to every physician between the ages of 22 and 55 in Oklahoma, but it is unsigned.

OREGON

Dr. Clarence J. McCusker, Portland, said: Our committees in Oregon are very much the same as those in many of the other states. The same confusion as to sending out a questionnaire occurs as in the questionnaires sent out by the government and the American Medical Association, and also one from the state society, which was furnished us by the Western Department of War at San Francisco. The one sent out by Colonel Lynch gave the best results, and those who said they would accept service were commissioned, some of them having been assigned to a base hospital, and they have made a trip over the state, and this has given the best results we have had so far. With this confusion of different agencies in asking for more men, I fear we are going to find it much harder to get the next 7,000 men than it was the first 7,000, and the next 7,000 will be still harder. We feel the need of a central agency and a classification of the men, so that we can put our finger on them and have the necessary authority to call on them when needed.

PENNSYLVANIA

Dr. Cyrus Lee Stevens, Athens, said: The question now is not what we have done, or what we have not done, but what are we going to do. I believe that each one and all of us propose to go over the top. My friend from Michigan (Dr. Warnshuis) did not exactly steal my thunder, but he used my ammunition, and did it so much more effectively than I could, that I will forgive him for it. As has been intimated by the chairman, our state has sent the second largest number of physicians. We are not planning to rest on anything we may have done, but are ready to take hold and continue our work and be loyal to our government, loyal to our profession and loyal to the organization, whether it be national, state or county.

What has been accomplished in our state is due to several things. I might mention some of them—organization and public professional spirit. All of our county societies have agreed to remit the dues of those who are in the service or in the service of any of our allies. The state society has remitted the per capita assessment of all such. Two of our county societies have insisted on paying the state society per capita assessment. Most of the county societies, not all of them, have promised to protect, so far as they can, the practice of those who have gone or who may go. This, of course, cannot be carried out without failures here and there, without imperfection and without possibly some friction, possibly some misunderstanding. Some have agreed to turn over as high as 60 per cent., some 50 per cent., some 40 per cent., and some 33.3 per cent., and this is being carried out as well as the circumstances of such a delicate thing will permit. This plan has its imperfections. THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION and our state journal have made constant appeals, which have gone a great way toward inducing physicians to make application to enter the Medical Reserve Corps. Another thing that h nabled us to do work has been the state committee of th f National Defense, Medical Section, which has rough work in Pennsylvania, largely through Dr. Codman and Major Jump and others. the department has made its mistakes, we hav duplications, and we know more now than began; but the committee deserves credit for what has been accomplished. We know pretty well the standing of each man. We have found that some of our rural communities, and not a few of our industrial communities, are really suffering for the want of medical men, and these should be cared for in some way.

RHODE ISLAND

Dr. J. W. Leech, Providence, said: I do not believe there is a lack of patriotism on the part of the profession in our state, but rather in large part it is due to a failure of the government to take men into the service promptly after they receive their commissions. When a man gets a commission, puts his house in order, and is anxious to get into the service, if he has to wait six months it is discouraging to him, and this of itself cannot fail to be detrimental to eligible men who have not received a commission. In a community with a medical population of thirty-eight, eight have accepted commissions, and only four of them have been called to active service. The result is discouraging. I would be in favor of a selective draft to call for physicians at the age of 55 who are physically fit. This is the only efficient and democratic way of getting a full Medical Reserve Corps into the service.

SOUTH CAROLINA

Dr. Edgar A. Hines, Seneca, said: Our work in South Carolina thus far has been similar to that in many other states that have already reported. Much of the work has been done through the state committee of the Council of National Defense. I believe that the public speaking method and the questionnaire method, particularly the latter method, have resulted in as many men as we are going to get. Our state association had a military program in the last few days. We had a representative from the Surgeon-General's Office, and many of the points that we did not understand were cleared up by him. I believe that we are now ready for more intensive work, and I think that this must be personal work. I have doubt about the feasibility of a county committee in a state like ours. I believe that a central committee probably will do the best work. I am convinced that now it is personally a question of putting it up to each man.

TEXAS

Dr. I. C. Chase, Fort Worth, said: We have 278 counties in the state, many of which are officered only by physicians who are encouraged and induced to stay, not because of the prosperity but because of the needs of the ranch people; consequently many of them stay. It is safe to say, after carefully looking over the state, that only seventy counties in the state have a sufficient medical population to furnish doctors. For that reason, seventy of the 278 counties have to furnish the quota for the entire state. Major Jump, in a recent itinerary, after looking the matter over, thought we had done well. I am frank to say that we should not have done so well had it not been for the terrible drought throughout the state which drove many rural districts into a bread and butter situation. The general situation there has been handled in a rather disastrous manner, commencing with a canvass of the state by the committee on medical preparedness, officered by two commissioned officers who are placed at the head in turn of the State Council of National Defense for the collection of statistics, and in turn removed, so that in coming into affairs recently and looking the matter over, I found that one of the two things essential for success in the work, the first and most important part, has been neglected. For that reason, we are compelled to begin again and take a very careful survey of every physician in the seventy counties in the state. This has cost the last two times over a thousand dollars each, and will cost more than that and occupy probably sixty days. We have a committee of forty, each having two counties. We have a committee of five in each of the seventy counties, in all about 400 men, with an office force to handle the work. At the end of sixty days we hope to have detailed information as to the age, physical condition, wife and number of children, property and income, and the needs of the community, etc., to enable the comm thoroughly to canvass the state, and probably select sand men and then begin the pressure.

UTAH

Dr. W. Brown Ewing, Salt Lake City, s all the problems mentioned here. The on us was the State Council of Def died last week. Major Jump was the embalming and it has been h new one is to spring up, and perhaps we can get something out of it. The one we had did not know anything, or did not do anything. I have the names of fifty-seven men who are actually in the service, approximately 15 per cent. of the profession of the state. I have obtained these names in every conceivable way except from headquarters. Before coming to this conference I convened our state council, some of the members of which are the most practical men in the state, to formulate some plan that I could suggest here, and asked for by the conference in conjunction with the suggestions from the various states, taking the good from each one and leaving out the bad. The plan suggested is something like this: that the country be circularized by the American Medical Association, giving the man's name, age, state and address; the college and year of graduation; the children he has under 10 years of age; debts on the home or obligations that the man was compelled to meet; his ability to serve in the Army in a general way or in a partial capacity; the condition of the individual's health, whether good, fair or bad; the special work he may be engaged in or special work in which he may be the most apt; the industrial position that he at present occupies, whether he is connected with mines, smelters or railroads, and if called into service, whether it would be possible for him to supply a substitute. If these questionnaires are collected at headquarters in Chicago, the American Medical Association can make a classification, say Classes 1, 2, 3 and 4. Class 1 will include men under 40 years of age, in good health, a man who has a wife and no children, or a wife and one child, who has no debt on his home, or the debt can be arranged for so as to be carried without hardship on the family, who has no industrial position or no industrial community to serve. I do not see why a substitute should not be provided in such a case. Class 2 will include men who have some disability or more home ties that might prevent them from going. Then, after the classification has been made, the Surgeon-General of the Army can notify the communities that a thousand men are needed. The American Medical Association can start out from its classification—and if it keeps the classification up as it has done in the past, it will certainly be complete—notifying the Surgeon-General that it has suggested a certain number from each state, giving their names and then send to each man a notification that his name has been sent to the Surgeon-General's Office as being eligible for service. Then whatever pressure can be brought from headquarters should be brought directly to bear on the individual himself. I submit this plan simply as suggestive.

VERMONT

Dr. W. G. Ricker, St. Johnsbury, said: It seems to be necessary that we have a census, an inventory, of the medical and surgical strength of the country. In this voluntary service, such as the gentlemen from Utah, Ohio, New Jersey and New York have described and suggested, there are objections to undertaking a volun[illegible]y census, as there are many replies that will not be returned. It is the [illegible]ht of the Surgeon-General's Office or the War Department, or the United States government, or the Pres[illegible], or whatever name you give to the authority, [illegible] know who we are and where we stand professionally, [illegible]ncially, socially and otherwise. Every suggestion that has [illegible] made in regard to the questionnaire today is valuable. [illegible]hat questionnaire be exhaustive; let it be prepared with [illegible]nd let it contain questions that will convey information. [illegible] he government in possession of the questionnaire, and [illegible] of it carefully tabulated, when the demand for [illegible]es and the government sends out a call that it wants [illegible] men who are operative surgeons, or 800 men who [illegible] have had operative surgical experience, that it [illegible]ty-five otologists capable of examining and car[illegible] in the Aviation Corps, or that it needs 100 [illegible]ists, and so on, it can get them. As I under[illegible]ading the correspondence of Dr. Craig, the [illegible]cal Association has made it a point of honor [illegible]he responsibility of supplying the Army with [illegible]rgeons. Is that approximately correct? [illegible] War Committee has undertaken to supply [illegible] not incompatible as an obligation, if [illegible] of the officers of the American Medi[illegible] and give directions. These are valu[illegible]k can be carried out in absolute [illegible]erican Medical Association. As to [illegible] there is nothing absolutely com[illegible]istration.

VIRGINIA

Dr. Paulus A. Irving, Farmville, said: We have 2,371 white and colored, allopaths and homeopaths. I should say of the 2,371 physicians in the state we have in our state medical society 1,800 or more. Three hundred and ninety-three of these are already enrolled in the Medical Reserve Corps—actively enrolled and seventy-one in the Navy, a total of 464. In addition to making this census, we have also made a survey of the profession in Virginia, and we have a complete record of every physician in the state. We have his name and address and age, whether married, single or widower; the number of children, their ages, and so on; whether his family is dependent on him; whether there is any physician in his community to take charge of his work and his practice in case he is called to the service; also the line of work that he is best qualified and adapted for, and whether he should be exempted; if so, the reasons therefor; the age and physical condition of the family dependents, etc. When we get to work on this survey we shall know exactly the number Virginia is called on to furnish, and letters will be addressed to these men by our committee for us, and we shall have a sufficient number of volunteers. Virginia, in the past, has furnished our government with its presidents. She stands ready to furnish the medical profession also.

WEST VIRGINIA

Dr. J. H. Anderson, Marytown, said: I am sorry to say that the organization with reference to securing these men for the National Army has not been what it should be. We have worked largely through the Committee of National Defense. When I received word from the secretary of the American Medical Association concerning this meeting, I prepared and sent out a little questionnaire of my own with reference to the state. I asked the number of physicians that have gone to war from the society and from every society in the state. I asked the number of physicians that have gone to war from the city in which the secretary of that society was located. I asked for the number remaining within the bounds of the society and the number of physicians in the bounds of the city. I asked what the civil population of the territory was, what the bounds of the society were, and what the civil population and bounds of the city were. I asked the men to whom I wrote, who were the secretaries of societies and councilors through the state, the number of men they had that could be spared. I asked these various secretaries whether they were in favor of conscription, and I received about fifty answers. It seems to be the opinion of a good many that the thing to do would be in some way to bring all of the members of the medical profession in our state within the ages thus designated by the government to a point where the government or the American Medical Association, or the people who know what the government wants, would be able to select whom they desire and the men best qualified for those places. I think if that were done, West Virginia will prove loyal and will come up to its quota, whatever you desire from us.

WISCONSIN

Dr. Rock Sleyster, Waupun, said: Shortly before the war, Wisconsin sent a man to the United States Senate who has given us a black eye. I want to assure you that he does not represent the sentiment of the state of Wisconsin. Of twenty-one states in the United States having 2,500 or more physicians, Wisconsin stands second only to Pennsylvania. The discussion today has been largely in the nature of an experience meeting. We have got together and told our troubles, and our troubles have been about the same in every section of the country. When all boiled down, it is about the sins of the volunteer system. We are taking men that ought not to go, and men that cannot be spared, the cream of the profession, men out of teaching positions and other places in professional life, where they should remain; and the slackers and fellows that ought to go are staying at home. It all comes back to this: How can we best bring about the spirit of selective conscription? It is probably impossible for us today to have selective conscription, but I think the results of this meeting should culminate in taking these ideals and putting them into action as soon as we can. I believe compulsory registration, as suggested by the secretary from Vermont, is the logical way of getting at it. The first thing to be done is to make a survey of every state in the Union. We have accomplished it in Wisconsin. Our questionnaire took in all of the information and points which have been enumerated by other questionnaires referred to today. We have a card index in my office which contains all this information of every man in the state. This ques-

tionnaire has been reenforced by a careful survey of every county society, and checking up the survey by councilors of the state medical society. I have repeatedly asked during the past six months several men to report fellows who could be spared, and, at the same time, place men who were poorly located in good positions, and it has been a good service in releasing men who were good material for the Army, without injury to the community which they served. With the information that we have gained of each physician of the state, I have worked out a rather elaborate classification showing the availability of each man, the things that are holding him back, and placing them in several classes regarding their availability. I shall be glad to submit this to whatever committee is appointed at this meeting. But first of all, a careful survey should be made to find out who can be spared and who should go, and bring proper force to get these men into the service.

TASK OF THE ORGANIZED MEDICAL PROFESSION

The Chairman introduced Dr. Arthur Dean Bevan, President-Elect of the Association, who said: I consider this meeting one of the most important that has ever been held under the auspices of the American Medical Association.

In the first place, we have got to find out what will probably be demanded of us. It is evident that this country is going to put in the field from 3,000,000 to 5,000,000 men. How does this affect the medical profession? We have in this country about 140,000 or 150,000 people who are licensed to practice medicine. The demands on that body will be probably somewhere between 30,000 to 40,000 before we are through with this job. Already about 21,000 are in the Army, and the Surgeon-General has called for another 5,000. The Surgeon-General of the Navy has called for 2,000 more men. In order to meet this demand it is evident that just what the American Medical Association is doing and what you gentlemen are doing is the first step, i. e., to ascertain the existing state of facts. This survey of the entire country, which will enable us to find out exactly how many medical men there are in each state and in each county, how many are male physicians, and how many have applied to join the service, and the percentages, will give us these necessary facts.

There are two problems with which we are confronted. The first problem is, we have got to secure the necessary number of medical men for the government. The second problem is not as important as the first, but it is a very important one, and it is that of securing the necessary number of men without crippling any locality or institution seriously. Both of these problems can be met by the organized profession of this country. I believe that each county and each medical school and hospital should furnish as a minimum 20 per cent. of its medical men, and as a maximum not more than 50 per cent.

I have been impressed with the fact that so far we have not organized this thing in the right way. We have had too many committees; there have been too many agencies attacking the problem, and it has not been handled in the best way. So far as the advisory committee of the Council of National Defense is concerned, we should remember that it is a body that is purely advisory; that it has no executive powers of any kind; that so far it has acted very largely through the county societies and state societies of the American Medical Association. This work should be done, as is contemplated, and as the Surgeon-General has requested, by the American Medical Association through its state and county societies. It is the job of the organized medical profession in this country. There is no other body of professional men in the world that is organized in such a representative way as the American Medical Association, and it is very fortunate that we have such an organization at this time to place at the disposal of the government.

I want to say that this country and the profession are very fortunate in having at the head of the Medical Department of the Army such a splendid figure as General Gorgas. I know, and you know, that he has the confidence of the entire medical profession; he has the confidence of the entire public, and I believe that we are in a position under the leadership of Surgeon-General Gorgas, and with the splendid organization we have in the American Medical Association, to take up this serious problem and carry it through in a splendid way so that in this great war the medical profession of this country will fully do its part.

MISSOURI

Dr. E. J. Goodwin, St. Louis, said: In lis remarks of the gentlemen from the differen thought has been forced on me stronger than eve has been splendid work done, especially in the states where there was close cooperation with county societies. In Missouri the county societies have worked with the Council of National Defense and in the city of St. Louis and in Kansas City splendid work has been done recently because the county medical societies of these cities are cooperating fully and harmoniously with the auxiliary committee of the Council of National Defense, Medical Section. In St. Louis we are just completing a survey similar to that reported by Virginia and other states.

Dr. Goodwin then presented the report of the Committee on Resolutions. (See The Journal, May 4, 1918, p. 1306.)

Medical Mobilization and the War

Personnel of the Medical Department

For the week ending May 10, 1918, the personnel of the Medical Department of the Army included:

Medical Corps: 869, includinig 1 major-general, 65 colonels, 110 lieutenant colonels, 298 majors, and 395 lieutenants.

Medical Reserve Corps: 18,833, including 1,281 majors, 4,629 captains and 12,923 lieutenants. On active duty: 16,690, including 1,205 majors, 4,277 captains and 11,208 lieutenants.

Dental Corps: 209; Dental Reserve Corps: 5,254, of whom 1,446 are colonels, 246 majors, 150 captains and 790 lieutenants.

Medical Corps, National Army: 115, including 3 brigadier-generals, 12 colonels, 92 lieutenant-colonels, and 8 majors.

Dental Corps: 209; Dental Reserve Corps: 5,254, of whom 1,446 are on active duty; Dental Corps, N. G.: 257; Veterinary Corps, 17; Veterinary Reserve Corps: 1,442, of whom 748 are on active duty; Veterinary Corps, N. G.: 41; Veterinary Corps, N. A., 476; Sanitary Corps, 1,031, and Ambulance Service, 160, constitute the remainder of the commissioned personnel.

The Discharges in all branches of the service to date are:

	Number				
Causes	M.R.C.	M.C.N.G.	D.C.N.G.	San.C.	D.R.C.
Physical disability	652	52	7	7	13
Inaptitude	245	20	0	2	5
Other branches	488	70	8	61	26
Resigned	112	33	4	7	8

The Surgeon-General's Office in New Quarters

The office of the Surgeon-General of the Army has moved into new quarters. Until recently it has been located in the Mills Building, at the corner of Seventeenth Street and Pennsylvania Avenue, Northwest, and in other buildings in that vicinity. It is now located in an extensive new building, of a temporary character, erected especially for its use, in the immediate vicinity of the Surgeon-General's Library and the Army Medical Museum, on the west side of Seventh Street, Northwest, just south of B Street.

Cited for Bravery

Lieut. George F. Patten, M. R. C., New York, has received the *croix de guerre* for risking his life to relieve suffering and wounded men under fire.

Forty-two medical officers and two sections of the American Ambulance Service were cited in orders by the French, April 20, for extreme courage in evacuating wounded under fire.

Missing Medical Officer Reported as Prisoner

Lieut. John S. Abbott, St. Paul, who was reported missing in The Journal for May 4, is now included in the official list as a prisoner in Germany. Lieutenant Abbott was captured on March 21 while on duty with an advance dressing station of the British Expeditionary Forces.

Wounded, Missing and Captured

Lieut. Clement A. Fogarty, M. R. C., severely wounded, April 18, while on a
His first active service was perform
Cambrai.

The following medical officers are reported in recent dispatches as wounded: Capt. Ernest W. Bertner, Houston, Texas; Lieuts. Daniel E. Berney and James E. O'Toole, Scranton, Pa.; Arthur S. Bugbee, Medina, N. Y.; Leonidas B. Faulk, Monroe, La.; William Michel, Frostburg, Md.; Daniel H. Lawler, Baltimore; W. J. McGregor, Wilkinsburg, Pa.; William J. Miehe, St. Louis, Mo.; R. Allyn Moser, Omaha, Neb.

The following medical officers are reported as missing: Capt. John F. Hardesty, St. Louis; Lieuts. Harold A. Goodrich, St. Louis; Thomas B. Kern, Bethlehem, Pa.; Frank K. Miller, Madera, Pa., and Maurice S. Redmond, Pittsburgh.

The following medical officers are reported as prisoners in Germany: Capts. Francis J. K. Hill, M. R. C., Brooklyn; Charles W. Maxson, Baltimore, and Lieut. Robert H. Jeffrey, Uniontown, Pa.

Year Book of the Medical Officers' Training Camp at Fort Riley, Kansas

The medical officers at the Fort Riley training camp have gone into the publishing business, the result of which is a very pretentious volume entitled the "Year Book of the Medical Officers' Training Camp at Fort Riley." The book is dedicated to Major-Gen. W. C. Gorgas, "who above all others has been responsible for the high standing of the Medical Corps of the United States Army and who now represents to the people of the country the ideal of an officer and a gentleman." It contains three full-page portraits of Major-General Gorgas, Colonels Munson and Bispham.

A foreword explains the organization of the camp. This is followed by a biography of Colonel Bispham, an article on the object of the camp, the headquarters, staff and history of Fort Riley, a roster of instructors, rosters of the twenty-three companies of medical officers, the base hospital, the Nurse Corps, the evacuation hospitals, the field hospitals, the ambulance companies, the hospital train, sanitary detachments, gas defense corps and other organizations making up the personnel of the camp. An excellently illustrated article by Charles Spencer Williamson describes the Fort Riley Sanitary Laboratory, of which he is director. Other articles concern the camp exchange, the Army Y. M. C. A., work in the camp and the department of physical instruction and recreation. The final portion of the book is in a lighter vein and is illustrated with many excellent cartoons. The book gives a thorough insight into the work done at this training camp for medical officers. The book contains matters of interest and value to those who propose to enter the Medical Reserve Corps. It will also prove to be a source of enjoyable reminiscence to every officer who has had the privilege of attending the courses at Fort Riley.

The enterprise of these officers should be encouraged, especially since the proceeds of the sale of the book are to be devoted to a worthy cause, namely, to financing a band for the Medical Department, for which the government furnishes no funds. The price of the Year Book is $2.50. The book may be procured by addressing the Year Book, M. O. T. C., Fort Riley, Kansas.

IMPRESSIONS OF THE FRONT

[Note.—*The following is taken from a personal letter received by the Editor of* The Journal *from Dr. Frank Besley, Chicago, now in France:*]

"The first week in January I was ordered away from this unit (Base Hospital No. 12, Chicago) and appointed consultant in surgery A. E. F. and assigned to duty with one of the divisions which went into training in the line with a French corps. While there I had a very unique experience and an unusual opportunity of studying the French medical organization from the front line trenches back along the lines of communication to the hospitals in the rear. I was greatly impressed with the French methods of dealing with their surgical cases. The prevailing conditions permit them to secure definitive surgical treatment in their wounded cases earlier than this is possible with the British forces. The reason is that along most of the French front there has been much less active fighting, and it has been possible to push more permanent hospitals closer to the front and to maintain them there.

The fundamental question involved in the care of a wounded soldier is entirely dependent on the length of time that elapses following his wound before he reaches a place where there are adequate facilities for giving him the proper care. Obviously this is entirely dependent on the kind of warfare that is being carried on and it is trite to say that during the last month it would have been impossible to have secured anything like proper facilities for doing excision of wounds and primary suture.

However, the transportation arrangements of the British are ideal and it is wonderful the number of wounded men that they handle. . . . It is with pleasure that the Regular Army Corps and the Reserve Medical Corps are working in the most perfect harmony and cordial cooperation. Naturally this sort of team work leads to the best possible treatment for the wounded American soldier and I believe he is getting it and will continue to get it. . . .

The arrangements that have been made with the British authorities for the sending of American troops to serve with the British forces will necessitate the caring for the American soldiers, and arrangements have already been perfected for carrying this out. At the present time we have about 150 American soldiers in this hospital and I presume that in the near future it will be entirely filled with Americans. . . . . . . The Journals continue to reach us regularly and they are a source of much satisfaction. The Red Cross Committee in Paris are furnishing us with copies of medical journals so that we are amply supplied."

"SECTS" NOT FOR MEDICAL SERVICE

Surgeon-General's Statement to the Adjutant-General of the Army

According to the *Army and Navy Register,* the Surgeon-General of the Army is opposed to legislation admitting osteopaths and other sects to the personnel of the Medical Corps. It quotes the following memorandum sent by Surgeon-General Gorgas to the Adjutant-General of the Army:

> The time has long passed for exclusive adherence to any particular school of medical doctrine or practice, such as is implied by the degree of doctor of osteopathy, of chiropractic, of naturopathy, of mechanotherapy, of eclectic medicine, or any other "pathy." The terms "allopathy," "old school," etc., are equally objectionable. A scientifically educated physician is at liberty, and it is his duty, to employ any method of treatment whatever which he believes will benefit his patient. Homeopathic physicians have the degree of doctor of medicine, and some of their schools furnish an adequate medical education. They have for the most part abandoned their exclusive dogmas; as a class they are rapidly declining in numbers and are being merged in the general profession of medicine. They are eligible to qualify for the Medical Corps of the Army. While practice based on the peculiar tenets of osteopathy may be beneficial in suitable cases, the same or similar methods are open to the use of any physician. Osteopathic procedures applied to cases unsuited for them, as has often been done, result in serious harm. The only safeguard against such adherence to exclusive systems is a good medical education, such as is now demanded for admission to the Medical Corps.
>
> It would be most objectionable to recognize any sort of medical practitioners in the Medical Department of the Army, be it osteopathic, allopathic, eclectic, chiropractic, or any other of the countless sects. Members of the regular profession of medicine, who now enter the Medical Corps, are merely educated physicians and do not constitute a sect in medicine, allopathic or otherwise. They are merely physicians free to follow any method of treatment which they may deem beneficial, in the same sense that a chemist is a chemist and a physician is a physician. It is argued that osteopathic physicians are trained in the principles of scientific medicine and are as well qualified as any physician to practice all branches of the profession. I have already indicated that, in my judgment, this is not true, but, if it were conceded, then the epithet "osteopathic," which sets these practitioners apart as a separate class or sect, could have no significance or value other than a commerical one, and this is not a principle which should be sanctioned in the constitution of the Medical Corps of the Army. . . . Whatever argument can be argued for the admission of osteopaths would apply equally to chiropractics and other medical sects. All cure their patients in certain cases; all do more harm than good when the balance between benefit and injury is struck.

The judge advocate general has advised the Secretary of War to the effect that, while the law does not specifically provide that a physician, in order to enter the Medical Corps, must be a doctor of medicine, unwritten practice does, and the secretary has decided in accordance with this opinion that he will require that a man coming into the medical corps shall have the degree of M.D. I hope that this decision, which is in accord with all previous practice, will be maintained, and that the degree of D.O. will not be recognized as an equivalent, as is desired by the osteopathic physicians.

The admission of osteopathic physicians as such and without the degree of doctor of medicine to the Medical Corps would have the practically unanimous opposition of the medical profession of this country and of all allied countries, would be regarded, and justly so, as lowering the standards, educational and professional, of our Medical Corps, and would have a discouraging and detrimental effect on efforts to secure physicians for the corps both now and in the future, and on the general morale of the corps.

THE MEDICAL OFFICER'S OUTFIT

[Note.—*At the request of The Journal, Major Frederick R. Green, M. R. C., secretary of the Council on Health and Public Instruction of the American Medical Association, has prepared the following article for the purpose of enlightening the civilian physician on the first problem that confronts him when, after accepting his commission, he is ordered to active duty. Major Green has been in active service in the Medical Officers' Training Camp at Fort Riley, Kansas, since last August, and for some months has been instructor. Hence he is qualified to write a practical article based on his own experience and observations.*—Ed.]

Equipment of the Newly Commissioned Medical Officer

What outfit does an Army medical officer need, and how much must he spend for his equipment? This question is probably being asked today by thousands of physicians, either those who have already accepted commissions in the Medical Reserve Corps or those who are seriously considering doing so. The civilian doctor about to enter Army life reads with growing confusion of cots, bedding rolls, trench boots, folding buckets, basins and lanterns. He hesitates between two dilemmas, and either comes to camp without the things he needs or arrives burdened down with an immense amount of baggage which he soon finds is not necessary. He is told on the one hand that a complete outfit can be purchased for $200, and on the other that his equipment will cost him from $600 to $800. What does he really need, and where can he buy to the best advantage?

These questions cannot be answered by the presentation of any one list. The answer rather is that the Army officer, like the technical worker in civil life, accumulates his working outfit as he needs it. There is no more reason for the Army officer to purchase his entire equipment at once than there is for a hospital intern, just beginning practice, to purchase a complete surgical equipment before opening his office. The extent of the outfit needed depends on the duty to which an officer is ordered. Is he going to training camp for a three months' course? Is he going direct to a base hospital? Or is he to be sent abroad at once? In each case his necessary equipment will differ. But few men are now being sent abroad without army training, and many of the medical officers ordered to base hospitals direct from civilian life are now being ordered into the training camps for delayed training. So in the average case, we can assume that the newly commissioned doctor will be ordered to training camp where he will stay for one to three months, that he will then be sent to a base hospital or assigned to a field hospital ambulance company or evacuation hospital, and that at the end of two or three months more he will go to France with his organization or be sent with a replacement detachment.

But this is in the future. What the newly commissioned officer wants to know is, "What must I get before I leave home for the training camp?" The best advise to give him is, "Buy only what is actually necessary to get you to the training camp; then complete your equipment during your stay in camp by getting what you find you need from time to time by actual experience, and secure the additional equipment for overseas service when you know you are going." There are many reasons for this advice. An officer who attempts to buy his entire equipment before leaving home may be discharged for physical disability and find himself with an expensive equipment for which he has no use. He may be assigned to restricted service, in which case he will not need an overseas outfit. No matter what his assignment, it is much better for him to purchase his outfit as he needs it from personal experience rather than to attempt to buy it complete on some other man's advice.

Equipment, then, may be divided into five groups. These are:

1. What an officer needs when reporting for duty. This he must buy before he leaves home.
2. Things he already has or can bring from home.
3. What he will need in a training camp or base hospital. These things he can and should buy after he reaches his station.
4. Articles, not necessary, but which may be purchased if desired
5. Additional articles for overseas service.

Taking these up in order, the first list would include:

FIRST LIST

	Minimum	Maximum
Uniform	$35.00	$75.00
Cap (regulation)	2.50	2.50
Pair shoes	4.50	18.00
Pair puttees	5.00	18.00
Set collar and rank insignia	2.00	2.00
Belt	.75	.75
Military locker trunk	6.12	15.00
Bedding roll	9.00	25.00
	$64.87	$156.25

SUGGESTIONS FOR PURCHASING

In purchasing a uniform, an officer has the same liberty that a civilian has in buying his clothes. He can get them ready made or have them made to order. He can get a cheap suit or an expensive one. Officers' uniforms are made of serge, wool or whip cord. They range in price from $35 for a ready made serge or wool uniform to $75 or $80 for a whip cord uniform made to order by a military tailor. A good uniform is a necessity so long as one remains in the service. It is advisable to get as good a uniform as one can afford. Wool is too hot for summer. Whip cord wears better than any other fabric, but is heavy and stiff. Probably the best thing for the average man is to get as good a serge uniform as he can afford. Ready made uniforms can be secured from dealers in any large city as Marshall Field, Mandel Brothers and the Hub, in Chicago, or Wanamaker in Philadelphia, or can be ordered by local clothiers from Hart, Schaffner and Marx, Kuppenheimer or other well known makers of ready made clothing. A regulation cap can be obtained from any dealer. It is worn only for dress, the field hat being worn in camp. Shoes cost from $4.50 in calf to $15 or $18 in officers' shell cordovan dress shoes. In whatever grade, they should be on the regulation Munson last. This is the best shoe ever made. Already shoemakers are beginning to modify this last in order to approximate the conventional narrow toed shoe. Insist on getting the original Munson last. Don't waste money on high priced cordovan dress shoes. You don't need them and you won't wear them. Get the regulation calfskin shoe and save your money for other things. Be sure the shoe fits, especially that it is wide enough. The same advice can be given about puttees. Prices range from $5 for cowhide to $18 for shell cordovan. Get a good pair of cowhide puttees, not too heavy, and be sure they fit, especially that they are not too long in the heel or under the knee. Let those who will pay $15 or $18 for pigskin or cordovan. Five or six dollars is enough, especially for camp wear. The belt should be the regulation webbing belt. Insignia include two U. S. R. and two caducei in bronze for the coat collar and two rank insignia for the shoulders. If you want to spend money, you can get sterling silver bars, but as you are going to be promoted soon, you might as well save your money and get white metal at 40 cents a pair. A regulation military locker trunk will cost from $6.12 to $15, depending on quality. Have your initials or name marked on each end and your name with "M. R. C., U. S. A.," on the top. A bedding roll is a canvas case for your mattress and beddi

It is also the catchall in which is packed everything that doesn't go in the trunk. It comes in dark brown or khaki colored canvas, with webbing straps. Prices range from $9 to $25. The $9 roll is just as good as any, but the straps are generally too small and too short. Get a pair of extra long webbing straps or two long trunk straps. Have your name stenciled on the outside of the bedding roll. What goes in the roll and how it should be packed will be considered later.

This is all that will be needed for the man ordered to port to a training camp or base hospital. It will enable im to travel to his post and report in presentable and proper condition without taking time or going to the expense of buying a lot of things that he won't need at all or that he won't need for a long time.

ADDITIONAL ARTICLES BROUGHT FROM HOME

In addition to these purchased articles, what does one need to bring from home? This is the second list. It comprises: pajamas; blankets; comfort or quilt; sheets, narrow, three pairs; pillow cases, three; slippers; bathrobe; tennis shoes; underwear; socks; handkerchiefs; toilet cases; white shirts; white collars; black tie; bath towels; blanket coat; coat hangers. Blankets for temporary use can usually be drawn from the quartermaster on memo receipt. Each officer should have at least two O. D. (olive drab) wool blankets for use in camp. For foreign service he is required to have four. If you can get the regulation U. S. O. D. wool blanket, get at least two; better three or four. If not, bring a pair of heavy blankets, preferably dark colored. Hudson Bay Company blankets are excellent if one can get them, in dark blue or gray. One or two cotton comforts or quilts add greatly to one's comfort in sleeping. Two blankets and a comfort are warmer than four blankets. Sheets are optional and depend entirely on one's personal preferences. Some officers prefer sheets and pillow cases. Others sleep between blankets. If you want sheets, bring three or four pairs of narrow ones for an Army cot. An ordinary sheet, split lengthwise down the middle and hemmed, will make a pair of about the right width. Three or four pillow cases may also be enough. Slippers may be leather or felt, but should be soft and easy. Bring an old bathrobe to wear to the latrine when bathing. If you have an old pair of rubber-soled tennis or gymnasium shoes, slip them into your trunk. They will give you much comfort in going to the bath house in wet weather and will keep your slippers dry. Underwear depends on personal preferences; wool, lisle or cotton, in two-piece, union or B. V. D., as desired. Bring plenty of it, whatever it is, for frequent changes are necessary. As to socks, probably the controversy will never be settled between those who like wool and those who don't. Some won't wear woolen socks; some won't wear anything else. *De gustibus non est disputandum.* Bring what you like, at least six pairs, and twelve are better. Handkerchiefs, at least twelve or better twenty-four, not too fine; some of these can be khaki colored. Some kind of toilet case is advisable; otherwise, toilet articles are scattered and lost. The Fitall cases in leather or canvas in varied sizes are excellent. One or two white shirts beside the one worn to report in and half a dozen white collars may be brought for special occasions. Leave shirt studs, valuable cuff buttons, watch chains, etc., at home; also valuable watches. Plain cuff buttons, a leather watch guard and a cheap but accurate watch are best. A black, narrow four-in-hand is the only tie worn. Face and hand towels are soon discarded. A blanket coat large, heavy bath towels serve all purposes. A blanket coat for evening wear in quarters is very comfortable. Half a dozen clothes hangers in wood or wire can be brought from home or bought at a 5 and 10-cent store. A stout and roomy laundry bag with a gathering string at the top and loops with which to hang it is a great convenience. All articles should be plainly marked. In a company barracks with a hundred men, *meum* is often very hard to distinguish from *tuum*. Of course, all these articles can be purchased at the camp exchange or at civilian stores after reaching camp, if desired.

PACKING

Now as to packing: Spread your bedding roll flat on the floor; turn out the flaps, head, foot and sides; fold blankets, comforts, quilts, sheets, etc., as nearly as possible the size of the bedding roll; lay in top of your bedding, as evenly as possible, your bath robe, blanket coat and anything else that you haven't room for in your trunk; fold the head and foot flaps, then the side flaps; tie the strings that hold the flaps in place; if you have a cot, place it, tightly strapped, across the head of the bedding roll; begin at the head and fold the roll over as tightly as possible; strap far enough from the ends to prevent slipping off; check the roll as baggage with your trunk.

TRAVEL ORDERS AND REPORTING FOR DUTY

As to procedure when you get your orders, "travel orders" always come from the Adjutant-General's Office and not from the Surgeon-General or from a bureau chief. Telegrams or letters from any one else than the Adjutant-General are preparatory, but they are not travel orders. Your telegram should read:

Washington, D. C., March 1, 1918.
First Lieut. John C. Smith,
Jonesville, Wis.:

You are assigned active service. Proceed to Fort Riley, Kan., and report, April 15, Commanding Officer, M. O. T. C., for course of instruction. Travel directed necessary in military service. McCain.

Several precautions should be exercised regarding this telegram. Do not accept it over the telephone. Insist on the local telegraph office giving you a written copy. When you receive it, be sure your name is correctly spelled and that the name of the receiving office is on the telegram. This telegram is worth money to you. Without it you cannot collect mileage. If your name is misspelled or if the town where you receive it does not appear, it is worthless. See that it is correct. Having received it, do not throw it into the wastebasket or leave it on your desk. Don't put it in the pocket of your civilian coat or lock it up in your trunk. Put it in your pocketbook with your money, and don't lose it. If you want transportation, take your orders to the nearest quartermaster or recruiting officer. He will issue a transportation certificate and stamp his notation on the back of your orders. Exchange the transportation certificate at the railroad ticket office for a ticket. Don't let the ticket agent take up your telegram.

When you get to your destination, ask any officer or noncom for the Headquarters Ambulance. There is always an ambulance to meet each train for the convenience of incoming officers. Be sure to go to the place your orders direct you to report to. If ordered to report to the Commanding Officer of a Base Hospital, don't report at Fort Headquarters. If ordered to report to the Commanding Officer, M. O. T. C., don't report at the Base Hospital. Go where you are told. When you get to Headquarters, ask for the Adjutant and hand him your orders. He will enroll you and assign you to quarters or tell you where to report.

ADDITIONAL EQUIPMENT FOR TRAINING CAMP

If ordered to a training camp, what additional equipment will you need?

ADDITIONAL EQUIPMENT FOR TRAINING CAMP

	Minimum	Maximum
Extra serge suit	$35.00	$50.00
Two pairs Munson shoes	9.00	16.00
Three or four flannel O. D. shirts	13.50	32.00
Field hat	2.50	6.00
Hat cord	1.50	1.50
Khaki suit	12.50	18.00
Three pairs khaki breeches	10.50	18.00
Sweater	7.50	10.00
Rain coat	2.60	50.00
Two O. D. blankets	6.12	6.12
Extra belt	.75	.75
	$101.47	$208.37

The extra serge suit is needed for a working suit, as long as serge is worn. Three pairs of shoes worn alternately will last five times as long as one pair worn continuously. At least three flannel shirts are needed. Four are better. They cost from $4.50 to $8 each. Get coat shirts of medium weight. The field hat is worn exclusively in camp. You can pay $2.50 for a regulation hat or $6 for a Stetson or Dunlap. Have your hat cord sewed on. Get an officer's hat cord, black and gold. Don't make the mistake the rooky did who came to camp wearing a General Officer's gold cord. He said that his girl gave him the handsomest one she could find as a Christmas present and he didn't like to hurt her feelings by not wearing it. Khaki is worn during warm weather. Get one blouse and three or four pairs of breeches. Be sure the breeches have hip pockets. Some haven't. Those that button at the knee are better than those that lace. Get a sweater, O. D. wool, to wear evenings. A raincoat is more necessary this time of year than any other. You can get a slicker, a poncho or a regulation raincoat for $2.00 from the Quartermaster, or you can pay $50 for an O. D. cravenette mackintosh, belted like a trench coat and lined with leather. There are many grades between. Have your rank stripes put on the sleeves. Two O. D. blankets will cost $3.06 each. An extra belt is a convenience. This additional equipment costs $101.47 minimum and $208.37 maximum. It can all be bought after reaching camp, either from the Q. M. at the camp exchange or at the civilian stores near camp. The assortment, quality and prices will be better than those in the local stores to which the average man will have access at home.

OPTIONAL PURCHASES

There are many things that are not necessary, that may be bought or not, as desired. These are:

OPTIONAL PURCHASES

	Minimum	Maximum
Mackinaw	$18.00	$25.00
Overcoat	35.00	75.00
Dress boots	18.00	35.00
Field boots	16.00	25.00
Rubber boots (hip)	3.50	12.00
O. D. wool uniform	35.00	50.00
Cot	3.50	4.50
Mattress	3.50	10.00
Chair	1.50	4.50
	$134.00	$241.00

Mackinaws are short coats originally worn by lumberjacks in the northern woods. They are short overcoats, belted like a Norfolk jacket. They are not regulation but are worn in camp in place of the long, heavy, cumbersome dress overcoat. The regulation overcoat is expensive and seldom worn. It is not worn abroad. Dress boots are calf, Russia or cordovan. Field boots are for rougher wear and lace over the instep or all the way up. Rubber boots are a necessity in camp in the spring. Wool uniforms are all right in winter, but are too heavy at any other time. They are required for foreign service. Whether you bring a cot or not, you will sooner or later want your own. The Gold Medal cot is used almost exclusively. The Medical Department special cot made by the company is higher, wider, stronger and covered with heavier duck than the ordinary cot. One costs $3.50; the other, $4.50. The larger cot is easily worth the difference in price. Every man will sooner or later want a chair of his own. The Gold Medal chairs are also best. They come in four or five patterns, from $1.50 for the camp stool, to $4.50 for a really comfortable folding armchair. Mattresses may be obtained in silk floss, cotton, felt or hair. The minimum cost of these optional luxuries is $134; maximum, $241.

OVERSEAS EQUIPMENT

Overseas service calls for some additional equipment. It includes: basin canvas; bucket canvas; O. D. wool uniform; compass; cup; field glasses; flashlight; gloves, leather and woolen; folding lantern; trench coat; overshoes; long woolen stockings; folding bathtub. It is not necessary to go into details in overseas equipment. Each man is given ample notice before going abroad and has plenty of time to complete the equipment. All needed articles can be secured at the Depot Q. M., at the port of embarkation. The cost of additional equipment will average about $100.

Summing up, the expense would be:

TOTAL EXPENSE OF EQUIPMENT

	Minimum	Maximum
Cost of equipment needed to report	$64.87	$156.25
Needed for training camp	101.47	208.37
Additional articles which are optional	134.00	241.00
Additional overseas equipment	100.00	100.00
	$400.34	$705.62

This expense, by getting an equipment as needed, can be distributed over two or three months, possibly more. No attempt has been made to attach any value to the articles to be brought from home, as these are already in the possession of most men, and their quality and cost varies with individual taste.

LIVING EXPENSES IN CAMP

What expenses does one have in camp? Very little, after one's outfit is completed. Mess bills are generally $1 a day, or $30 a month. Soap, matches, tobacco, cigars or cigarets, newspapers, postage stamps, stationery, all depend on individual taste as at home. An occasional trip to town with a dinner and a moving picture show is not very expensive dissipation, especially to those used to city prices. Laundry at the Post Laundry is cheap and generally good. Probably $50 or $55 a month would cover all necessary expenses, including mess bills.

Allowance must be made for difference in prices in different localities as well as individual taste. The articles recommended and the prices quoted above are based on nine months' experience in training camp, three as a student officer and six as an instructor. They are not intended to be dogmatic, but merely as suggestive opinions for the guidance and help of those about to enter the service.

NEWS OF THE CANTONMENTS

Thirty-First Division, Camp Wheeler, Macon, Ga.

May 3, 1918.

Camp Wheeler has gone through another epidemic of pneumonia, this time a small but virulent one. The epidemic of influenza, noted in April, was followed by a considerable number of cases of pneumonia: mostly of the streptococcus type—*Streptococcus hemolyticus*. There were cases of the old time "congestion of the lungs" with rapid consolidation, and in some cases death within twenty-four hours. Serum and empyema were also common, adding to the mortality.

The influenza is now past and the pneumonia almost past. During March there were only a few cases weekly, but in April the number increased to as many as sixteen in one day, and totaled ninety-five cases. Our sick report jumped to 8.4 per cent., the highest of any National Guard Division, but is now below 4 per cent. again. It is hoped that this is the last serious epidemic, though measles and mumps are expected with the new draft men. The continued cold, wet weather was favorable to influenza and pneumonia.

NEW RECRUITS

The whole division is deeply interested in the expected arrival of 10,000 recruits—select men. By some strange whirl of the wheels, these men come to the Dixie Division from Illinois and Michigan. No one is displeased, however, by that arrangement. It is expected that they will have less measles and mumps, and, above all, less pneumonia than the men from the Southern states. They will be held in a detention camp until examined and various vaccinations completed. This draft will fill the division to war strength. The arrival of a new general and men to fill up the organizations, together with completion of equipment, lead many to think that the division may at last actually cross the pond.

PERSONAL

Major Gaylord, M. R. C., is to be surgeon of the detention camp, with Major Pendleton as chief examiner, and some forty other medical officers as assistants.——Lieutenant-Colonel Weed, sanitary inspector, has arrived for a sanitary inspection of the camp.

Lincoln Division (Eighty-Fourth), Camp Zachary Taylor, Louisville, Ky.

May 13, 1918.

The convalescing infirmary of the base hospital is nearing completion, and some of the twelve two-story barracks have been occupied. When in full operation the infirmary will be a reclamation and reconstruction camp as well as a place for treatment of convalescing patients. With a view of conserving man power, selected men found to have slight physical defects will go through a course of training to b
them up and make them fit for active military servic

PERSONAL

Capt. Lee L. Ernstberger of Louisville, as
ca surgeon, Lieut.-Col. John H. Allen, is
other duties, as instructor in mi

first aid training at the School for Chaplains, vice Capt. David N. Roberg, who was relieved.——Lieut. Charles B. Matthews, formerly a physical director of Lexington, Ky., who has charge of giving medical attention to the families of officers and enlisted men of Camp Taylor living in Louisville, has been promoted to captain.

SCHOOL FOR CONVALESCENTS

A circular memorandum form the office of the Adjutant-General of the Army, received here, directs that all patients sent before the surgeon to be examined with a view to discharging them on surgeon's certificate of disability, and who come under the heading of border line cases, will not be discharged but their service records will be indorsed "fit for domestic service only."

All such doubtful cases covering both mental and physical defects, will be held to service in the United States for such work as they may be capable of performing. With the adoption of this method of conserving the man power of the nation announcement is made that arrangements are being completed for the opening of the convalescing infirmary at the base hospital, one of the sections of which is a reconstruction plant to reclaim patients having slight defects that might otherwise disqualify them from active military service.

MEDICAL STAFF AIDS RECRUITING

Lieut.-Col. John H. Allen, division surgeon, and a dozen other medical officers left Camp Zachary Taylor to visit sixteen towns in Indiana in connection with the efforts to secure additional medical officers for the Army. They will address meetings arranged by the Indiana State Medical Association. The medical association of the Hoosier state recently requested Major-Gen. Harry C. Hale, commander of the Lincoln Division, to assign medical officers to address meetings it would arrange.

General Hale granted leave of absence of two days to medical officers who volunteered to go out on their mission at their own expense. Sunday F. E. Rashig, acting executive secretary of the Indiana State Medical Association, came here to confer with Lieut.-Col. John H. Allen and final plans for the trips were made. The itineraries follow: Corydon, Capt. John J. Moren of Base Hospital Unit No. 40; Crawfordsville, Lieut. John Irwin, base hospital; Bluffton, Capt. Roy B. Storms, 159th Depot Brigade; Richmond, Capt. H. J. Ware, 159th Depot Brigade; Marion, Major Granville S. Hanes, Base Hospital Unit No. 40; Connersville and Rushville, Capt. Cecil I. Wayman, 159th Depot Brigade; Newcastle, Capt. Paul B. Coble, base hospital; Greenfield, Lieut. David C. Morton, contract surgeon; Linton and Loogootee, Lieut. Col. C. J. Imperatori, 309th Sanitary Train; Mount Vernon and Versailles, Capt. Miles F. Daubenheyer, 159th Depot Brigade; Logansport, Capt. David N. Roberg, division surgeon's office; Columbus, Capt. Michael R. Larkin, base hospital; Indianapolis, Lieut.-Col. John H. Allen, division surgeon.

REJECTIONS

To date the number of rejections at this cantonment for physical disabilities is approximately 3,000. However, it is likely that some men who were discharged at the outset and who had but minor defects may be recalled and accepted for limited service.

Only those found to be entirely unfit for any service are now discharged from the National Army. Borderline cases now coming to the attention of the medical officers here are classified "for domestic service only" on their records. They are kept under observation and given scientific medical treatment in an effort to upbuild the weak parts. The reconstruction method was put into operation Monday at the convalescing infirmary at the base hospital.

CLEAN UP AT WEST POINT

Lieutenant Sandidge of the United States Public Health Service has appointed Dr. D. C. Roberts, assistant surgeon for the service in West Point. Together they are planning a complete clean up of the town. Streets, fountains, even those sacred precincts, family kitchens, every nook and every corner are to come under their wary eyes. The main street of West Point will have their first attention, it being their purpose to have the street cleaned immediately and its dust laid for the summer.

SURGEON-GENERAL BLUE HERE

Surg.-Gen. Rupert Blue, of the United States Public Health Service, spent Friday at the cantonment, accompanied by Major L. D. Frick, who is stationed at Louisville. He conferred with Lieut.-Col. John H. Allen, division surgeon, and Lieut.-Col. Will L. Pyles, commander of the base hospital, regarding health conditions here and in the territory surrounding the reservation. The department which General Blue heads is especially responsible for health conditions in a 5-mile radius of military camps.

DISEASE CONDITIONS AMONG TROOPS IN THE UNITED STATES

From Telegraphic Reports Received in the Office of the Surgeon-General for the Week Ending May 3, 1918

1. ANNUAL ADMISSION RATE PER 1,000 (Disease only):

All Troops	1,109.7
National Guard Camps	994.
National Army Camps	1,222.4
Regular Army	1,054.1

2. NONEFFECTIVE RATE PER 1,000 ON DAY OF REPORT:

All Troops	39.1
National Guard Camps	35.6
National Army Camps	43.8
Regular Army	37.4

3. ANNUAL DEATH RATE PER 1,000 (disease only):

All Troops	6.3
National Guard Camps	3.6
National Army Camps	6.3
Regular Army	8.19

ORDERS TO OFFICERS OF THE MEDICAL CORPS AND OF THE MEDICAL CORPS OF THE NATIONAL ARMY

To Camp Forrest, Chickamauga Park, Ga., for duty, from Camp Sheridan, Lieut. EDMUND B. SPAETH.

To Camp Gordon, Atlanta, Ga., for duty, from Camp Sevier, Lieut. HASKETT L. CONNER.

To Camp Lee, Petersburg, Va., for duty, and on completion *to his proper station*, Lieut.-Col. EDGAR KING. For duty, from Camp Dodge, Lieut.-Col. CLARENCE E. FRONK. As assistant to the camp surgeon, from New York City, Lieut. DAVID H. W. GRANT.

To Camp Upton, L. I., N. Y., and *Hoboken, N. J.*, for duty, and on completion *to his proper station*, Col. DEANE C. HOWARD.

To Chicago, Ill., for duty, and on completion *to his proper station*, Col. REUBEN B. MILLER.

To Dansville, and *East Aurora, N. Y.*, for duty, and on completion *to his proper station*, Lieut.-Col. JOHN A. HORNSBY.

To Fort Jay, N. Y., for physical examination to determine his fitness for active duty, and on completion *to his home*, Major CHARLES W. FARR.

To Fort McHenry, Md., for examination to determine his physical fitness for active duty, and on completion *to his home*, Major HARRY R. BEERY.

To Fort Oglethorpe for duty, from Camp Wadsworth, Major WILLIAM W. PERCY.

To Hoboken, N. J., for temporary duty, from Rochester, N. Y., Col. GEORGE A. SKINNER.

To Hot Springs, N. C., for inspection, and on completion *to his proper station*, from Biltmore, N. C., Lieut.-Col. WILLIAM H. SMITH.

To Mineola, L. I., N. Y., for consultation, and on completion *to his proper station*, Col. WILLIAM O. OWEN.

To New York City, for duty, and on completion *to his proper station*, Lieut.-Col. WILLIAM F. LIPPITT.

To Ordnance Proving Ground, Aberdeen, Md., and *Gas Shell Plant*, Edgewood, Md., for sanitary inspection, and on completion *to his proper station*, Col. ALBERT E. TRUBY.

To Washington, D. C., for consultation, and on completion *to his proper station*, from Hoboken, Col. GUY L. EDIE; from Camp Devens, Lieut.-Col. WILLIAM A. POWELL; from Fox Hills, Lieut.-Col. HENRY H. RUTHERFORD. On completion *to New York City*, Major PHILIP B. CONNELLY.

To Whipple Barracks, Ariz., for duty, from Fort Bayard, Major CARL E. HOLMBERG.

Honorably discharged on account of physical disability incurred in line of duty, Major ROBERT E. SIEVERS.

ORDERS TO OFFICERS OF THE MEDICAL RESERVE CORPS

Alabama

To Camp Gordon, Atlanta, Ga., for duty, Capt. JOHN R. OSWALT, Union Springs. Base hospital, from Camp Wheeler, Lieut. EDWARD C. HAGLER, Northport.

To Camp Pike, Little Rock, Ark., base hospital, *from* Camp Bowie, Lieut. LEO C. WOODS, Birmingham.

To Camp Shelby, Hattiesburg, Miss., base hospital, Lieut. BISHOP B. WARWICK, Talladega.

To Camp Wadsworth, Spartanburg, S. C., for duty, from Fort Oglethorpe, Lieut. JAMES R. HAIGLER, Montgomery.

To Fort Oglethorpe for instruction, Lieut. SAMUEL S. UNDERWOOD, Anniston.

To Pittsburgh, Pa., Pittsburgh University, to make physical examinations and give medical attention to the drafted men to be enrolled at this institution, from Garden City, Lieut. WILLIAM R. ROUSSEAU, Huntsville.

Arizona

To Camp MacArthur, Waco, Tex., as member of the board examining the command for tuberculosis, Capt. ROY E. THOMAS, Phoenix.

Arkansas

To Camp Lewis, American Lake, Wash., base hospital, from Camp Cody, Lieut. HENRY W. A. LEE, West Helena.

To Fort Oglethorpe for instruction, Lieuts. ERNEST M. McKENZIE, Dardenelle; ERNEST DARNALL, Wildener.

To Jefferson Barracks, Mo., for duty, from Camp Bowie, Lieut. JOHN R. BROWN, Mansfield; from Camp Pike, Lieut. NOLIE MUNCY, Little Rock; from Fort Riley, JACOB LER. PRITCHARD, Winslow.

California

To Rock Island, Ill., for duty, from Camp Logan, Capt. FRED F. SPRAGUE, Los Banos.

Honorably discharged in order that he may accompany a mission to Persia, Capt. JOSEPH W. COOK, Redlands. On account of physical disability existing prior to entrance into the service, Capt. CARO W. LIPPMAN, San Francisco.

The following orders have been revoked: *To Camp Kearny*, Linda Vista, Calif., base hospital, Capt. FREDERICK A. COLLER, Los Angeles; To Fort Oglethorpe, base hospital, Capt. LAWRENCE H. HOFFMAN, San Francisco.

To Camp Cody, Deming, N. M., base hospital, Capt. HERBERT P. NOTTAGE, Oakland.

To Camp Kearny, Linda Vista, Calif., base hospital, Capt. HENRY W. MILLS, San Bernardino; from Fort Riley, Lieut. WALLACE DODGE, Los Angeles.

To Fort MacDowell, Calif., for duty, Lieut. JOHN P. STRICKLER, San Francisco.

To Fort Riley for instruction, Lieuts. WILLIAM A. SWIM, Los Angeles; ERNEST C. GRINER, San Francisco.

To New York City, Cornell Med. Coll., for instruction in military roentgenology, from Fort Riley, Lieuts. JOSEPH SAYLIN, El Monte; FREDERIC B. WEST, Los Angeles; ROBERT A. POWERS, San Francisco; BYRON Y. MILLER, San Luis Obispo.

To report by wire to the commanding general, Western Department, for assignment to duty, Lieut. PAUL K. JACKSON, San Luis Obispo.

To Washington, D. C., for duty in the Surgeon-General's Office, from Fort McHenry, Major HOWARD C. NAFFZIGER, San Francisco.

To the inactive list, from Camp Fremont, Lieut. FRED O. BUTLER, Eldridge.

The following order has been revoked: *To Camp Fremont*, Palo Alto, Calif., for duty, Capt. WILLIAM W. CROSS, Fresno.

Canal Zone

To Fort Oglethorpe for instruction, Lieut. HARRY G. EBERSOLL, Balboa Heights.

Colorado

To Camp Cody, Deming, N. M., base hospital, Capt. CYRUS L. PERSHING, Denver.

To Camp Jackson, Columbia, S. C., as assistant to camp surgeon, from Fort Oglethorpe, Capt. EDWARD J. SCANNELL, Trinidad.

To Fort Riley for instruction, Lieut. DALTON K. ROSE, Denver.

To New York City, Cornell Medical College, for instruction in military roentgenology, from Fort Riley, Lieut. WALTER K. HOTCHKISS, Brighton.

Connecticut

To Camp Sherman, Chillicothe, Ohio, base hospital, from New York City, Lieut. FRANK I. RONAYNE, Hartford.

To Fort Adams, R. I., for duty, Lieuts. FESSENDEN L. DAY, Bridgeport; HOWARD D. MOORE, Danbury.

To Fort Oglethorpe for instruction, Capt. FRANKLIN L. LAWTON, Hartford; Lieuts. FRED F. ARMSTRONG, Ansonia; JAMES R. KNOWLES, Danielson; HERMAN P. DAVIDSON; BERNARD F. GILCHRIST; CHARLES F. McGUIRE, New Haven.

To Fort R. G. Wright, L. I., N. Y., for duty, Lieut. GEORGE P. CHENEY, New London.

To New Haven, Conn., for duty, Lieut. BERNARD C. MARANTZ, New Haven; from New York City, Capt. JOHN B. GRIGGS, Hartford.

To Walter Reed General Hospital, Takoma Park, D. C., for duty, from New York City, Lieut. MAX CLIMAN, Hartford.

District of Columbia

To Dayton, Ohio, Wilbur Wright Field, for duty, from Walter Reed General Hospital, Capt. EDWIN M. HASBROUCK, Washington.

To Mineola, L. I., N. Y., Signal Corps Aviation School, for duty, from Washington, D. C., Capt. CHARLES W. HYDE, Washington.

The following order has been revoked: *To Camp Greene*, Charlotte, N. C., base hospital, Capt. DANIEL D. V. STUART, Jr., Washington.

Florida

To Camp Joseph E. Johnston, Jacksonville, Fla., base hospital, Lieut. OTIS G. KENDRICK, Tallahassee.

To Fort Riley as orthopedic surgeon, from Cincinnati, Capt. HENRY C. DOZIER, Ocala.

Honorably discharged on account of physical disability existing prior to entrance into the service, Lieut. HUBER P. NEWMAN, Bartow.

The following order has been revoked: *To Fort Oglethorpe* for instruction, Lieut. CAREY P. ROGERS, Jacksonville.

Georgia

To Camp Jackson, Columbia, S. C., for duty, from Fort Oglethorpe, Lieuts. BUFORD C. BIRD, Colquitt; EVERETT J. STOTHART, Savannah.

To Camp Laurel, Laurel, Md., for duty, from Fort Oglethorpe, Lieuts. FRANCIS M. BURKHALTER, Ray City; ORLANDO S. WOOD, Washington.

To Columbus, Ohio, Ohio State University, for duty, from Atlanta, Lieut. ERNEST S. COLVIN, Atlanta.

To Fort Oglethorpe for instruction, Capt. WILLIAM R. McCURRY, Hartwell; Lieuts. CHARLES H. DICKENS, Lawrenceville; MILTON WALTON, Lumpkin; RUPERT H. STOVALL, Macon; SOLOMON YOUMANS, Normantown; LEE HOWARD, Savannah.

To Camp Gordon, Atlanta, Ga., base hospital, Capt. FREDERICK G. HODGSON, Atlanta; from Camp Wheeler, Lieut. CYRUS K. SHARP, Arlington. For duty, Lieut. THOMAS H. SMITH, Atlanta.

To Camp Joseph E. Johnston, Jacksonville, Fla., for duty, Lieut. WILLIAM J. MYERS, Savannah.

To Camp Meade, Annapolis Junction, Md., to examine the command for nervous and mental diseases, from *Washington, D. C.*, Lieut. JAMES K. PETTIT, Milledgeville.

To Fort Oglethorpe for instruction, Capt. DANIEL B. EDWARDS, Savannah; Lieuts. WILLIAM C. BLANDFORD, EDWIN N. MAUER, Atlanta; JOHN K. BURNS, Jr., Clarkesville; WILLIS P. JORDAN, Kirkswood; SOLOMON YEUMANS, Normantown. For duty, Lieut. BENJAMIN E. GRAHAM, Gurley.

Honorably discharged on account of physical disability existing prior to entrance into the service, Lieuts. JOHN W. ODEN, Blackshear; THOMAS J. BLACKSHEAR, Dublin.

Idaho

To Jefferson Barracks, Mo., for temporary duty, from Fort Riley, Lieut. DUNCAN L. ALEXANDER, Twin Falls.

Honorably discharged on account of physical disability incurred in line of duty, Capt. OSWALD F. HENNING, Jerome.

Illinois

To Camp Greene, Charlotte, N. C., base hospital, from Camp Sherman, Capt. WALTER D. STEVENSON, Quincy.

To Camp Hancock, Augusta, Ga., base hospital, Lieut. VERGIL ROSS, Chicago; from Camp Dodge, Capt. PRESCOTT BENN

Washington; from Camp Joseph E. Johnston, Lieut. WALTER A. FORD, Kankakee; from Camp Meade, Lieut. THOMAS R. MAXWELL, New Berlin.

To Camp Jackson, Columbia, S. C., base hospital, from Boston, Lieut. HERBERT B. HENKEL, Springfield; from Camp Lee, Lieut. WILLIAM J. SIEGLER, Chicago. For duty, Lieut. ANTON J. FIRTIK, Chicago.

To Camp Kelly, San Antonio, Tex., for duty, from Camp MacArthur, Lieuts. WILLIAM H. EVANS, Murphysboro; HARRY H. HANLY, Peoria.

To Army Medical School for instruction, from Fort Oglethorpe, Capt. VICTOR M. DALY, Pontiac.

To Camp Cody, Deming, N. M., base hospital, Lieut. WALTER M. PRUYN, Chicago.

To Camp Custer, Battle Creek, Mich., base hospital, Lieuts. CLARNCE H. BOREN, HARRY C. DUNLAVY, Chicago.

To Camp Dix, Wrightstown, N. J., for duty, from Rantoul, Lieut. JAY T. WOOD, Springfield.

To Camp Dodge, Des Moines, Ia., base hospital, Lieut. SAMUEL L. THORPE, Clinton.

To Camp Forrest, Chickamauga Park, Ga., for duty, *from Camp Doniphan,* Capt. CARL L. BARNES, Chicago.

To Camp Kelly, San Antonio, Tex., *for duty, from* Camp MacArthur, Lieut. ALEXANDER A. DRILL, Chicago.

To Camp Meade, Annapolis Junction, Md., base hospital, from New York City, Capts. WINFIELD G. McDEED, *Monticello;* HUGH L. MARSHALL, Stronghurst.

[illegible] othe, Ohio, *Camp Dodge,* Des Moines, Ia., [illegible] Ill., for conference, and on completion *to his proper station,* Major ALLEN B. KANAVEL, Chicago. As assistant to camp surgeon, *from* Camp Devens, Capt. FREDERICK A. FISHER, Chicago.

To Colonia, N. J., for duty, Major SAMUEL R. SLAYMAKER, Chicago.

To Fort Leavenworth, Kan., for duty, from Camp Dodge, Lieut. CARL F. LEWIS, Jerseyville.

To Fort Logan, Colo., for temporary duty, and on completion *to his proper station,* from Camp MacArthur, Lieut. BERNARD BENKENDORF, Chicago.

[illegible] instruction, Capts. EDWARD J. WHEAT-L[illegible]L, Mt. Vernon; Lieuts. TOM F. BEVER-I[illegible]AN, HENRY G. LESCHER, DAVID J. [illegible]PITZ, EUGENE A. RUSH, ITALO F. [illegible] FREDERICKSON, Plano; MANUEL M. I[illegible].

To Fort Riley for instruction, Lieut. HARRY LEWIN, Chicago.

To Hoboken, N. J., base hospital, from Hoboken, Major DANIEL M. OTTIS, Springfield. *For duty,* Lieuts. ARCHIBALD C. WEAVER, Hoopeston; WYLIE L. KELL, Mt. Vernon; LEWIS J. WEISHEW, Oswego; from Camp Crane, Lieut. GEORGE E. O'GRADY, Chicago.

To Jackson Barracks, La., for duty from Camp MacArthur, Lieut. ERWIN R. SCHMIDT, Chicago.

To Jefferson Barracks, Mo., for temporary duty, Lieut. WALTER A. DAY, Fosterburg; from Camp Beauregard, Capt. HARRY ROBENSTEIN, Chicago; from Camp Dodge, Capt. DUNCAN B. McEACHERN, Chicago. On completion *to his proper station,* from Camp Dodge, Lieut. JOHN O'CONNELL, Chicago.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education, public health, etc.)

ALABAMA

Health Officers' Meeting.—At the meeting of the association of county and city health officers of Alabama, held in Birmingham, April 19, Dr. Judson D. Dowling, health officer of Birmingham and Jefferson County, was elected president, and Dr. John M. Lowrey, assistant city health officer of Birmingham, secretary and treasurer.

The State Association.—The annual session of the Medical Association of the State of Alabama was held in Birmingham from April 16 to 19, under the presidency of Dr. William D. Partlow, Tuscaloosa. At a patriotic meeting held on the evening of the second day, a service flag bearing 437 stars was presented to the association by Major James N. Baker, M. R. C. The following officers were elected: president, Dr. Isaac L. Watkins, Montgomery; vice president, for the northern district, Dr. Henry S. Ward, Birmingham; secretary, Dr. Henry G. Perry, Montgomery (reelected); treasurer, Dr. Jacob U. Ray, Jr., Woodstock (reelected); censors, Drs. Glenn Andrews, Montgomery, Samuel G. Gay, Selma, and Charles A. Thigpen, Montgomery; councilors, first district, Drs. Claude N. Lacey, Demopolis, John A. Kimbrough, Thomasville, and Percy J. Howard, Mobile; second district, Drs. John C. McLeod, Opp, and Russell A. Smith, Brewton; third district, Dr. George W. Williamson, Hartford; fourth district, Dr. Lee R. Wright, Heflin; eighth district, Drs. Alva A. Jackson, Florence, Hugh Boyd, Scottsboro, and Edwin V. Caldwell, Huntsville; ninth district, Dr. James M. Mason, Montgomery, and tenth district, Drs. William E. Howell, Haleyville, and Robert L. Hill, Winfield. A memorial session was held in honor of the late Dr. William H. Sanders, Montgomery, state health officer, at which appropriate resolutions were adopted.

DISTRICT OF COLUMBIA

Lectures on Public Health.—Surgeon-General Gorgas has arranged for a series of health talks to be given to civilian employees of the War Department, to be held Tuesday and Thursday afternoons in the auditorium of the Department of Interior Building. Among the lecturers are Col Frederick F. Russell, Lieut.-Col. William H. Welch, Elliott G. Brackett, Frank Billings and William H. Smith; Majors William J. Mayo, George L. DeSchweinitz, John R. Murlin and Leonard G. Mitchell; Kate B. Karpeles, acting assistant surgeon, U. S. Army; Miss Annie Goodrich, and Miss M. Sanderson.

ILLINOIS

Action in Regard to Venereal Diseases.—At its April meeting at Rock Island, the Rock Island County Medical Society passed a series of resolutions in which it urges the Secretary of War to create a military medical organization embracing every qualified physician, for the purpose of a continuous fight against venereal disease. A full outline of the purpose, duties, and method of procedure of such an organization was prepared and forwarded with the resolutions. This action is taken in cooperation with similar action by the medical faculty of the state university, the Iowa State Council of National Defense, and a number of county medical societies.

Chicago

Personal.—Mr. Peter Reinberg, president of the Cook County board of commissioners, has appointed Dr. Haim I. Davis assistant physician of the Cook County Psychopathic and Detention Hospital.

INDIANA

Hospital to be Taken Over.—Hope Hospital of Fort Wayne will be taken over immediately for operation under the direction of the Methodist Hospital, Indianapolis. Dr. Charles S. Woods, superintendent of the Methodist Hospital, will be superintendent of Hope Hospital, with an assistant actively in charge there.

Health and Defects Among Schoolchildren.—A meeting has been called by Dr. Herman G. Morgan, Indianapolis, secretary of the board, to devise means for a higher standard of physical health among schoolchildren. Investigation will be made of all schoolchildren in this city in order to find the number of children physically defective.

LOUISIANA

Personal.—Dr. Henry B. White, Lake Charles, medical inspector of the state board of health, has resigned.——Dr. Robert W. Faulk, city health officer of Monroe, fractured his arm recently while cranking his automobile.——Dr. William Schulze, formerly city health officer of Monroe, has resigned to accept the position of medical inspector for the Baltimore and Ohio system at Hagerstown, Md.

MARYLAND

Meetings.—A joint meeting of the Howard, Carroll and Baltimore County medical associations was held, May 15, at the Springfield State Hospital, Sykesville. The principal address was delivered by Dr. C. Hampson Jones of the state department of health, on "The Diagnosis of Smallpox." The members of the associations were guests of the hospital at luncheon.

Personal.—Dr. Herman F. McPherson of Centerville, Md., has been appointed health officer for Queen Anne's County and physician to the county jail.——Dr. Abbott R. Walker was recently appointed health officer for Frostburg, by the Frostburg city council.——Dr. Samuel J. Fort, Catonsville, major in the ordnance department, Maryland National Guard, has been drafted into the federal service and assigned to duty at the school of musketry established at Camp Perry, Ohio.

MASSACHUSETTS

Personal.—Dr. Timothy Leary, medical examiner for Suffolk County, recently fractured his right forearm while cranking his automobile.——Major Frederick L. Bogan, Boston, who was graduated from an officers' training school in France, has been appointed commanding officer of the One Hundred and Second Field Hospital. He has been with the American expeditionary forces since September, 1917.——John P. Reynolds, Boston, has been made a trustee of the Peter Bent Brigham Hospital, and Drs. David L. Edsall, Milton, and Joseph E. Lamoureaux, Lowell, members of the public health council.

MISSOURI

Personal.—Dr. Joseph B. Cowherd has resigned as physician in charge of the eye, ear, nose and throat work of the Kansas City school hygiene staff, and has been succeeded by Dr. Thomas T. Sawyer.——Dr. Abraham Weinberg, for eight years physician to the Kansas City General and Emergency hospitals, James I. Gyree, head of the contagious disease division of the Kansas City Board of Health, and Abraham Sophian, meningitis expert of the board, have resigned.

MONTANA

Antituberculosis Meeting.—At the annual meeting of the Montana Association for the Study and Prevention of Tuberculosis, held in Helena, April 18, Dr. A. D. McDonald, superintendent of the state tuberculosis sanatorium, Galen, delivered an address on the relation of the work of the sanatorium to that of the association.

NEW MEXICO

State Board Appointment.—Dr. Walter E. Kaser, Las Vegas, has been appointed a member of the state board of medical examiners, succeeding Dr. Rice K. McClanahan, Las Vegas, who resigned to enter the naval reserve.

NEW YORK

Personal.—Dr. Grace A. B. Carter obtained the highest mark in the competitive examination for city physician of Rochester, held February 28.——Dr. Anna I. von Sholly, Flushing, who went to Europe with the Woman's Overseas Hospital, U. S. Army, is now on duty with the Service de Santé behind the French lines.——Dr. Vittorio Risicato, Albany, is now a captain in the Italian Medical Service and on duty with field hospital O 165 at the front.——Dr. Arthur W. Hurd, medical superintendent of the Buffalo State Hospital, has resigned and will reside in California.——Dr. Frank W. Ross, Elmira, is seriously ill with pneumonia at his home.

The Buffalo Academy of Medicine Protests Against A tude of American Red Cross Toward Research Wor

a meeting called for the purpose of considering the action of the American Red Cross in revoking its decision to appropriate money for animal research work, the Buffalo Academy of Medicine decided to transmit its protest to the American Red Cross, to the local Red Cross and to the medical journals. In this protest it states that Red Cross money could not be better used than in the establishment of a biologic laboratory near the war zone for the study of the diseases of soldiers, particularly those of trench warfare, and thus through animal experimentation probably save the lives of thousands of soldiers. It also contends that this decision of the Red Cross, made in compliance with the wishes of an intolerant minority of its supporters, may be establishing a precedent with far reaching detrimental results, and it urges the medical profession to resist fettering influences such as that which caused the Red Cross to withdraw its support from animal research.

Whitney Measure to Control Venereal Diseases.—The Whitney bill, said to be the most drastic health measure ever enacted by any state, went into effect, May 5. The bill was passed at the request of the federal government and is designed to protect soldiers and sailors against venereal diseases. This bill provides for the arrest and detention of persons afflicted with venereal disease during treatment. The enforcing of the law is placed mainly in the hands of local health boards. The New York City Health Department has taken immediate steps to assist in the enforcement of this law by sending health department officials to the night court. All prisoners will be held for diagnosis. After that, those found to be suffering from venereal disease will be held in city hospitals, or may be released at the discretion of the health authorities on guarantees that they will receive treatment. Men as well as women are being arrested. The state health department, in cooperation with the federal authorities, has outlined an extensive program which, in addition to necessary educational features for both physicians and the public, includes provisions for increased diagnostic facilities, for the manufacture and free distribution of arsphenamin (salvarsan) or one of its substitutes, for free advice and treatment of infected persons unable to pay for it, and for the taking of steps to secure greater hospital facilities for those in need of such care or for those who would otherwise be a danger to the community.

New York City

Tablet Given Society.—At the meeting of the Kings County Medical Society, April 16, Dr. Lewis S. Pilcher presented to the society a plaster cast of the tablet erected 600 years ago in the church of San Vitale, Bologna, Italy, by Mundinus di Luzzi, the anatomist.

Personal.—Dr. Abraham Jacobi, "The Grand Old Man of Medicine," celebrated his eighty-eighth birthday, May 5. He is still actively engaged in the practice of medicine.——Dr. A. J. Kemp was a passenger on the steamship *City of Athens*, which was rammed and sunk by a French war vessel off the coast of Delaware, May 1.——Dr. Frederick S. Kolle fell from a window of his residence in Brooklyn, April 23, fracturing his skull and both patellas.

Columbia University Lengthens Medical Course.—A resolution presented by the Columbia faculty of medicine, adding a clinical year to the medical curriculum, has been adopted by the trustees of the university. A plan for the fifth year has been outlined whereby there will be a redistribution of clinical subjects, which will be transferred to the final clinical year. The clinical year will be conducted under college discipline, and will be made effective for the class entering in September, 1918.

New Base Hospital Completed.—The United States Base Hospital at *Fox Hills*, Staten Island, is completed and ready to care for wounded soldiers. This hospital is said to be the largest on the Atlantic coast and has been erected in record time. It was started ninety days ago, within which time seventy-five buildings have been completed. Among the buildings are three hospital buildings equipped with 1,000 beds each. Major C. A. Simons is in charge of the hospital. It is reported that the government has plans for doubling the size of the hospital.

Roosevelt Hospital Unit.—The annual report of the Roosevelt Hospital, just made public, describes the work of the Mackay Unit of the Roosevelt Hospital in France, where it has recently had under treatment 3,200 patients. Dr. Charles H. Peck, major, M. R. C., is director of the unit; Dr. James I. Russell, major, M. R. C., is chief of the surgical staff and Dr. Rolfe Floyd, major, M. R. C., is chief of the medical staff. Twenty other members of the visiting and house staffs of the hospital are with the unit, also sixty-five nurses and picked men from other professions and trades, which number brings the personnel of the unit up to 150.

Halt Health Department Investigation.—Announcement has been made by James E. McBride, civil service commissioner, that the health department inquiry has been indefinitely postponed and that future investigation will be in the hands of the health commissioner, Dr. Royal S. Copeland. Dr. Sigismund S. Goldwater sent in his resignation as a member of the advisory board of the department of health. This Dr. Copeland has refused to accept and signifies his intention of retaining both Dr. Goldwater and Dr. Abraham Jacobi. Dr. Charles F. Bolduan has sent in his resignation as director of the bureau of public health education, which has been accepted.

Volunteer Nurses.—Shortage of nurses has resulted in the placing of volunteer assistants in seven of the city's large hospitals, Bellevue, Presbyterian, St. Luke's, Vanderbilt Clinic, the Lying-In, Gouverneur, and the Italian. To train women for this service, a new course has been arranged for hospital clinical assistants by Teachers' College in cooperation with the Bellevue Social Service, the Federation for Child Study, and the People's Institute. The course will give special training in child hygiene, nutrition and related subjects. It is pointed out that the employment of these clinical assistants not only helps out the shortage of nurses but results in a great saving of time to the physicians, of whom there are now none too many in the hospitals. In order to speed up the training of public health nurses, the Red Cross has given the Henry Street Settlement $25,000. The Henry Street course will be open to three-year undergraduate nurses and the course will continue from June 1 to September 1.

Older Physicians Needed in Dispensaries.—At a recent meeting of the New York Academy of Medicine, Dr. Charles L. Dana, chairman of the public health committee, brought to the attention of the members the fact that the withdrawal of physicians from civil life into military service has created a shortage of men in the dispensaries of this city, resulting in a curtailment of the services of these institutions. When further calls were made on the medical profession, the dispensary service would be still further decreased unless steps were taken to provide substitutes. Dr. Dana stated that this problem had arisen in Boston and had been met by appealing to the older men in the profession, who had passed beyond the dispensary stage and who, because of age or for other reasons, were not available for military service. These men were asked to volunteer for dispensary duties as their contribution to the war. A similar appeal was now made to the older physicians in New York to come forward and help out in the dispensaries.

NORTH CAROLINA

New Health Editor.—April 15, the state board of health announced the appointment of Donald B. Wilson as health editor for the board.

Health Officers' Meeting.—At the eighth annual meeting of the North Carolina Health Officers' Association, held in Pine-Hurst, April 15 and 16, Dr. J. Rufus McCracken, Waynesville, was elected president, Dr. D. F. Long, Lexington, vice president, and Dr. George M. Cooper, Raleigh, secretary-treasurer.

New State Society Officers.—At its sixty-fifth annual meeting held in Pinehurst, from April 16 to 18, under the presidency of Dr. Isaac W. Faison, Charlotte, the Medical Society of the State of North Carolina decided on Pinehurst as the meeting place for 1919. It elected Dr. Cyrus Thompson, *Jacksonville*, as president, and reelected Dr. Benjamin K. Hays, Oxford, as secretary-treasurer.

NORTH DAKOTA

Now in Government Service.—Former employees of the state laboratory, W. W. Hanford, bacteriologist and chemist, and G. E. Richardson and B. C. Ford, bacteriologists, now belong to the United States Sanitary Corps.——Edwin M. Santon, formerly bacteriologist of the St. Mary's Hospital, Detroit, Mich., has been appointed bacteriologist in charge of the Bismarck station.

OHIO

State News.—Plans for the construction of a contagious diseases hospital to cost $6,000 are being arranged at Lorain.

——The Ohio Supreme Court has upheld a hospital bond issue of $35,000, at Circleville, which was attacked on a technicality.——At Ravenna, the Visiting Nurse Association, during the week of March 18, raised funds to the amount of $2,000.——The Mississippi Valley Conference on Tuberculosis will meet in Columbus in September, at which time and place the Ohio Society for the Prevention of Tuberculosis will also meet.——Dr. Albert C. Carney was recently elected president of the Hamilton Antituberculosis League.

PENNSYLVANIA

Philadelphia

University Hospital Unit Arrives.—May 6, news was received of the safe arrival in England of the United States Base Hospital Unit No. 20, recruited by the University of Pennsylvania and under the directorship of Major John B. Carnett.

Personal.—At the meeting of the Atlantic County Medical Society, Atlantic City, May 10, Major William M. L. Coplin, M. R. C., delivered a lantern slide demonstration showing "the care of wounded from trench along the line of communication to base hospital." Dr. Pascal B. Bland gave an illustrated address on a "General Consideration of Uterine Cancer with Special Reference to Its Diagnosis."

Tablet to a Physician.—In memory of Earl C. Peck, who died Sept. 5, 1916, from infantile paralysis contracted in the course of his duties at the outbreak of the epidemic, a tablet has been placed in the corridor of the administration building of the Philadelphia Municipal Hospital for Contagious Diseases. Dr. Peck was the first assistant physician in the scarlet fever ward of that institution, and on the appearance of infantile paralysis was assigned to the supervision of the department in which such cases were received. While engaged in the work, Dr. Peck contracted the disease. The tablet was erected from a fund raised by a number of friends.

TENNESSEE

Hospital Enlarged.—The hospital of the Tennessee Copper Company at Copperhill, Tenn., is being enlarged so that patients besides the employees of the company may have the service of the hospital. The physicians connected with the hospital are Dr. Chauncey W. Strauss, chief surgeon, and Dr. Thomas J. Hicks.——Dr. Charles G. McMahon, formerly of Copperhill, has located at Miami, Ariz.

VIRGINIA

Personal.—Dr. Richard W. Garnett, formerly of Charlottesville and recently health officer of Fauquier County, has accepted a position on the state board of health as an inspector of contagious diseases.

Typhoid Clinic.—At Richmond, the health department has opened a free clinic for the examination of citizens and the giving of antityphoid vaccine. The clinic is located in the health department and is open each day from 8:30 to 9:30 a. m. May 10, there were eight cases of typhoid fever in the city. All of the patients, it is believed, contracted the disease outside.

For a Base Hospital.—The property of the Richmond and Westhamptom College at Westhampton will be taken over by the United States government for the establishment of a base hospital. This action has the consent and approval of the college authorities, who are making the arrangements elsewhere for the conducting of the college classes. All the laboratory facilities of the college likewise are to be turned over to the government.

Vital Statistics and Midwives.—Previous to this year, Virginia had no law providing for and regulating midwives. The legislature of 1918, however, has passed a law for this purpose and the bureau of vital statistics of the state department of health has perfected and sent out to the physicians and to the midwives circulars of instructions in regard to the requirements of the law for reporting births, for using the drops to prevent blindness, etc. The pamphlet contains instructions for midwives in regard to the care of women during confinement, and a pledge card to be signed by those applying for licenses as midwives by which they agree to comply, in all respects, with the law for reporting births within ten days. The circulars of information also contain suggestions for registrars, undertakers, and for the public in regard to the importance of reporting births and deaths. The license permit issued to midwives has on the back ten fundamental rules to guide them in caring for women during confinement. It is expected that the result of this campaign will greatly improve the facilities for compiling the vital statistics of the state.

CANADA

University Admits Women.—McGill University has opened its doors to women. They are henceforth to be admitted to the study of medicine and dentistry. Those to be admitted hereafter must have a degree in arts from a recognized university, or must take the double course of B.A. and M.D., or B.Sc. and M.D.

Personal.—Capt. Frederick C. Harrison, C.A.M.C., Toronto, is now employed in connection with the medical service of the Royal Air Force in that city.——Major Harry H. Alger, Stirling, Ont., who has been overseas, has gained his lieutenant-coloneley, and has served in various capacities in England and France. He has recently been appointed assistant inspector of drafts, headquarters' staff, Shorncliffe area.——Lieut.-Col. John N. Gunn, C.A.M.C., who practiced in Calgary, Alta., as an eye specialist, is in Toronto on sick leave, convalescing from trench fever. He says that General Porter, director of the British medical service in France, paid a glowing tribute to the work of the Canadian Army Medical Corps. Never before in the history of the war had such dispatch been shown by stretcher bearers as that shown at Paschendaele. There has never been a complaint from any branch of the Canadian force about the work of the C.A.M.C.

Canadian Medical Week.—Canadian medical week will be celebrated in Hamilton, Ont., from May 27 to June 1, when a congress of Canadian organizations, including the Ontario Health Officers Association, the Canadian Public Health Association, the Canadian Association for the Prevention of Tuberculosis and the Canadian Medical Association, will assemble under the auspices of the Ontario Medical Association. The combination has been made in the interests of war time efficiency. The sessions will be held at the Royal Connaught Hotel. The first two days will be occupied by the programs of the two health associations, the third by the program of the Canadian Association for the Prevention of Tuberculosis, and the last three days, by the joint program of the two medical associations. Among the interesting events scheduled on the joint program are two addresses, one on "Cancer," by Dr. Charles H. Mayo, president of the American Medical Association, and one on "Medical Impressions of the Day," by Dr. Frank Billings of Chicago. The last day of the congress, Drs. Mayo and Billings will also conduct a combined medical and surgical clinic on the subjects of simple and toxic exophthalmic goiter, anemias, and focal infections. Other noteworthy features of the congress will be the meetings of the various sections, a round table discussion on a subject of vital interest to the profession, business sessions of the different organizations, class reunions and sectional dinners, and a varied display of scientific exhibits. The last feature includes a series of moving pictures shown daily on medical subjects, especially those dealing with war surgery; an exhibit of roentgen-ray plates; a pathologic exhibit of museum specimens taken largely from the National War Museum of Canada; a demonstration of clinical laboratory procedures, and a display of charts, illustrations and literature from the propaganda department of the American Medical Association, together with a lantern slide demonstration of the work of the Association.

GENERAL

Society Meeting.—The twenty-third annual meeting of the American Academy of Ophthalmology and Oto-Laryngology will be held in Denver, August 5, 6 and 7. Dr. Lee Masten Francis, 636 Delaware Avenue, Buffalo, is the secretary.

Clinical Society Organized.—The seventh annual clinic of the John A. Andrew Memorial Hospital, Tuskegee, Ala., closed, April 13, with the formation of the John A. Andrew Clinical Society, which elected Dr. Charles V. Roman, Nashville, Tenn., president; Dr. Charles W. Powell, Atlanta, Ga., vice president, and Dr. John A. Kenney, Tuskegee, secretary-treasurer.

Colored Professional Men Hold Conference.—The annual meeting of the Tri-State Medical, Dental and Pharmaceutical Association was held at Memphis, Tenn., from April 9 to 11 under the presidency of Dr. J. H. Howard, and the follow officers were elected: president, Dr. Joseph H. B

Marianna, Ark.; vice presidents, Drs. Milton V. Umble, Oakland, Tenn.; J. T. Brasfield, Isaac Carroll, F. T. Jones and W. T. Sherrett, Memphis, Tenn.; corresponding secretary, Dr. Robert G. Martin; recording secretary, Dr. Robert B. Pruett, Jackson, Tenn., and treasurer, Dr. S. W. Pope.

Association of American Physicians.—At the recent meeting of the Association of American Physicians, May 7 to 11, the following officers and new members were elected: officers for 1918-1919: president, Dr. Alexander McPhedran, Toronto, Ont.; vice president, Dr. Hermann M. Biggs, New York; secretary, Dr. Thomas McCrae, Philadelphia; recorder, Dr. William W. Ford, Baltimore; treasurer, Dr. Joseph A. Capps, Chicago; councilors, Dr. Theobald Smith, Princeton, N. J., and Dr. Charles F. Martin, Montreal, Que. Active members: Drs. Frederick M. Allen, W. H. Brown, Haven Emerson, Theodore S. Hart, New York; Frank T. Fulton, Providence, R. I.; James D. Heard, Pittsburgh; Thomas Ordway, Albany, N. Y.; George M. Piersol, Philadelphia; Henry S. Plummer, Rochester, Minn.; Gerald B. Webb, Colorado Springs, Colo; Solon M. White, Minneapolis; Simeon B. Wabbach, Boston. Associate members: George Draper, Reginald Fitz, New York; Joseph S. Evans, Madison, Wis.; Herbert Z. Giffin, Rochester, Minn.; Martin E. Rehfuss and John H. Musser, Philadelphia. The 1919 meeting will be held in Atlantic City during May.

FOREIGN

The Italian Weeklies.—The *Riforma Medica, Gazzetta degli Ospedali* and the *Policlinico* now reach us without any cover and minus the advertising pages. A notice states that the authorities have ordered that from now till the end of the war, journals to be sent out of the country should be made up without any advertising pages.

College of Ambulance.—The College of Ambulance in Vere Street, London, has been in existence five years and 20,000 students have passed through it. They have been trained for ambulance and first aid work in military and civil practice. Through the efforts of Sir James Cantlie and Sir James Reid, it is hoped to have a chair of ambulance founded in the University of London, and affiliated with the medical schools.

Repression of Venereal Diseases in Spain.—A royal decree dated March 15, 1918, outlines a system for antivenereal dispensaries throughout the country and medical inspection of prostitutes with hospital care for venereal diseases. The dispensary and hospital service is gratuitous, and the expenses are to be shared by the town, district and state authorities. The military commander in the district is to be a member of each Junta provincial de Sanidad in charge of the campaign against venereal diseases.

Pneumonic Plague.—Dr. Charles W. Young, dean of Union Medical College, Peking, China, has gone to Shansi, taking with him Dr. Chang of the staff of the college, who has had experience in work with the plague in Tientsin. His mission is educational, and he hopes to persuade the governor of the province to stop traffic on the Hwang-Ho River which flows through Saratsi where pneumonic plague is very prevalent. In one town north of the Great Wall, it is said that 1,000 persons died from the disease in five days.

Repatriation of Members of Medical Corps.—The *Presse Médicale* of April 18 states that arrangements have been concluded according to which medical officers, nurses and others covered by the Geneva convention are to be repatriated regularly every two months. The first trainload had already left Constance, and the next is to leave Lyons next month. If the registers and archives of the *formations sanitaires* to which they belonged have been destroyed, the statement of the government to which they belong will be accepted as certifying to the probable correctness of their claims to be of the medical force.

Medical Inspection of Schools in Spain.—The minister of public instruction in Spain has obtained from the king a decree establishing medical inspection of schools in Madrid and Barcelona. There are to be ten inspectors at each place, and the salary is to be 3,000 pesetas annually, about $600, but as only 25,000 pesetas ($5,000) has been appropriated for the purpose, the inspectors are expected to serve without pay until the next budget is made up. The positions are to be filled by competitive examinations in each city; at least five years of practice are required. A *Boletin de la Inspeccion Medicoescolar* is to be issued, to publish the reports of the inspectors and their suggestions. According to *Esculapio,* forty-three candidates have registered at Madrid and thirty-two at Barcelona.

LONDON LETTER

London, April 23, 1918.

Physicians and the Military Service Bill

The new military service bill extends the obligation for military service to all British subjects who have not attained the age of 51 years. In the case of physicians the obligation extends to those who have not attained the age of 56 years. In consequence of the shortage of physicians now left in civil practice, the withdrawal of still more is a serious matter. Sir Auckland Geddes, the minister of national service, stated in parliament that there are districts, in which, as the result of the withdrawal of physicians, the supply available is very short, and the young man that is fit is as necessary as in the trenches, and is working practically as hard day and night. It is no good putting an old man who does not know the district and does not know the people into that position. Unsatisfactory medical attendance and the collapse of the physicians would result. It has been tried. In the medical profession, youth and fitness are now required for certain districts at home just as much as at the front. But there are great base hospitals where the work is not normally very hard, so the government is considering whether it cannot make use of some of the older physicians. It has surveyed the whole country. It has plotted out in every town the number of physicians available and the number of the population they may have to look after, and it finds that there are in some of the more comfortably off residential cities, not the great manufacturing cities, but cities in which a retired class live, physicians of from 50 to 54 that are in excess of local requirements. They have comparatively speaking, a small number of possible patients at any time. These men can go without dislocating either the public health service or the ordinary service of attendance on the sick, and they are sufficiently fit for work in the base hospitals. The question is to meet the medical demand for the forces of the army in the way that will make least disturbance at home and without doing harm to the civil population. Physicians are always coming back from overseas to their practices to release a partner, or something of the sort. If physicians were moved from town A to town B so as to replace those who had gone into the service, an enormous amount of trouble would be created and problems raised as to the adjustment of practices and compensation for removal, which can be avoided.

More German Brutality to Prisoners

In a recent letter (The Journal, March 23, 1918, p. 867) was described the organized German brutality to British prisoners captured in the early stages of the war. It was there remarked that subsequently the treatment of British prisoners, though leaving much to be desired, had improved, principally because we had a large number of German prisoners in our hands. Unfortunately, from time to time fresh outbreaks of barbarity of the worst kind have to be recorded. All England has been horrified by the account of the British sailor who was bayoneted by the German sentry because he was trying to escape from the flames of his burning prison. The German government has had the effrontery to give as an excuse that the sentry could not allow the man to escape because there was no officer present to authorize him! We have now another record of systematic cruelty in a report just issued by the Government Committee on the treatment of British prisoners of war, signed by the chairman, Mr. Justice Younger. It has been communicated through the Dutch to the German government. Overwhelming evidence has been received that: 1. British prisoners of war were employed within 30 kilometers of the firing line at least as early as July, 1916, that is, a considerable time before the German government denied that such employment had commenced and sought to justify it as an act of reprisal. 2. These prisoners were treated with the utmost brutality, and most of the deaths at Dulmen attributed by the Germans to such causes as heart weakness and intestinal catarrh were, in fact, directly due to starvation and ill treatment on the western front. 3. Although an agreement was concluded between the British government and the German government at the end of April, 1917, not to employ prisoners of war within 30 kilometers of the firing line, British prisoners were, up to the time of the most recent information, being employed within that limit. 4. British prisoners were treated with extreme brutality on the western front, being forced to work on totally insufficient food, until rendered useless owing to extreme weakness. They were employed on work directly barred by Article 6 of the Annex to the Hague convention, such work being immediately connected with the operations of war. These men continued to arrive during the autumn and winter of 1917 at hospitals and camps in Germany in a state of misery and semistarvation. Although the fact had never been acknowledged, but on the contrary studiously concealed, there is no doubt that since as early at the latest as August, 1916, the Germans have been systematically employing prisoners on forced labor close behind the firing line, thus deliberately exposing them to the fire of their own guns. As usual, when conduct incapable of justification has been brought to light, the official German apologist has endeavored to gloss over it by asserting that Germany was driven to it by way of retaliation for similar treatment of German prisoners. The allegation is unfounded. The British prisoners were placed all the way along behind the German front in Belgium and France, large numbers being stationed at Cambrai and Lille. Their work included making roads, repairing railways, digging trenches, constructing wire entanglements, making gunpits, loading ammunition, filling munition wagons, and carrying trench mortars--work forbidden by the laws of war. The work, excessively hard, lasted from eight to nine hours a day, with long walks to and fro, sometimes 6 miles in each direction, and for long periods was carried on within range of the guns of the Allies. Many were killed by these guns; more were wounded; deaths from starvation and overwork were constant. Appalling evidence is given concerning the systematic semistarvation of the prisoners. "We used to beg the sentries," said a witness giving evidence as to conditions at Marquion, "to allow us to pick stinging nettles and dandelions to eat, we were so hungry; in fact, we were always hungry." Another witness from Cambrai said: "If it had not been for the French civilians giving us food as we went along the roads, we should most certainly have starved. If the sentries saw us make a movement out of the ranks to get food they would immediately make a jab at us with their rifles." But it was worse at Moretz, where "if a man stepped out of the ranks he was immediately shot. . . . Two instances are given in the evidence of men who weighed 13 st. [a stone is 14 pounds] when captured. One was sent back from the firing line too weak to walk, weighing 8 st. only; the other escaped to the British lines weighing no more. Another man lost 2 st. in six weeks. Such was their hunger that we hear of them picking up for food potato peelings that had been trampled under foot. One instance is given of an Australian private who, starving, had fallen out to pick up a piece of bread left on the roadside by Belgian women for the prisoners. He was shot and killed by the guard for so doing. The parcels, on which British prisoners so much depend, did not reach these prisoners for the reason that their presence in occupied territory was not acknowledged by the German government. When they wrote home they were required to give some prison camp in Germany as their address. Sometimes their very existence was concealed for months. To add to their miseries, the accommodation provided was in many cases pathetically inadequate. One sleeping place, for instance, for a large party was a barn with no roof. The rain poured in on the men. They had to sleep in their wet clothes and work in the same clothes. They had no change of any kind. And some of these prisoners, if they survived so long, were kept behind these enemy lines for more than a year. When utterly worn out they were sent to Germany.

PARIS LETTER

Paris, April 11, 1918.

Valvular Disease of the Heart from Military Standpoint

At a recent meeting of the Société médicale des hôpitaux de Paris, Dr. Paul Lafosse read a very interesting paper on this subject. Supported by many observations, he has been able to confirm the great tolerance, even indifference, to fatigue at the front of men affected with valvular lesions. These observations appear to show conclusively that there is no reason whatever for definitely excluding from the military service men who have valvular lesions. Lafosse claims that auxiliary service is compatible with the well-being of nearly all of these men, whether their condition was congenital or acquired. Nevertheless, according to the degree, the age and the manner in which the heart responds to the demands made on it, will depend the nature of the auxiliary service and whether this will be rendered at the front or in the interior.

In the discussion of this paper, Dr. Josué, physician to the hospitals of Paris, stated that all physicians have had occasion to note that individuals presenting irrefutable evidence of valvular lesions have, nevertheless, been able to lead very active lives without any functional disturbance. As a matter of fact, however, because of the existence of the valvular lesion, the fitness of the individual is more or less impaired. Josué has confirmed this observation daily among a very large number of subjects submitted to examination and to a special military consultation at the hôpital de la Pitié, but he says that it will be difficult to lay down absolutely uniform rules. A number of persons affected with a valvular lesion are able to perform very important work, provided one knows of what they are capable and without imposing on their strength, and allowing them to have periods of rest. Therefore, it is proposed to certify for auxiliary service all patients having never presented any symptoms, from their valvular disease, and also those with a lesion not well marked and perfectly compensated. In some cases the lesion is very slight, noticeable only after violent efforts, and these persons should be recommended for auxiliary service, stating precisely how they should be managed, that they are not fit for heavy work, and that they should be under constant medical supervision. If the man presents any symptoms, such as slight dyspnea, fatigue, etc., which it is believed will disappear after rest and treatment, the man should be invalided temporarily. In cases of marked disturbance, threatening loss of compensation, or complete arrhythmia, the patient should be discharged from service.

Vocational Training of the Disabled, and the Teaching Personnel

According to the law bearing on the reeducation of the *mutilés* passed in January, 1918, all soldiers and sailors, or former soldiers and sailors, who have been wounded or who contracted disease, or whose illness was aggravated during the present war, may demand to be enrolled in a school of vocational reeducation for the purpose of being trained to work again, and be helped to secure a position. With the consent of the premier, the minister of war and the commissioner general of *les oeuvres d'éducation professionnelle des mutilés,* the minister of public instruction has addressed a circular to the teaching personnel in which he points out in a striking manner the necessity of keeping in mind the importance of the reeducation, for the men themselves and for their families. By profiting by the training the disabled man is shielded from the depressing effects of idleness; he resumes his place in *l'activité nationale;* he escapes the risks of a temporary placement, due to passing circumstances; he escapes the mirage of a public office—the number of political positions is limited, and their security does not compensate for the poor remuneration. Often, too, this reeducation makes it possible for him to secure a better position than that which he had held previously. One can no longer count the *mutilés* who, having learned a new trade or having perfected themselves in the one they followed before the war, are now leading a much ampler existence. All this, it must be said again and again, is in the interest of the wounded, their families and their country.

The minister stated that he is ready to study all the suggestions presented by any of the teaching personnel in the institutions for the purpose in the line of improving the general or vocational training of the disabled.

Marriages

Lieut. Lecky Harper Russell, M. R. C., U. S. Army, of Columbus, Ohio; on duty with the One Hundred and Forty-Seventh Field Hospital Corps, U. S. Army, stationed at Camp Sheridan, Montgomery, Ala.; to Miss Carita L. Kimball of Lawrence, Mass., at Covington, Ky., May 2.

Capt. John Vaughn Blake, M. R. C., U. S. Army, Floresville, Texas, on duty as battalion inspector at Camp Greenleaf, Ga., to Miss Mary Long, Del Rio, Texas, at Chattanooga, Tenn., April 13.

Joseph T. Scott, Williamstown, Ky., to Mrs. Helen J. White, Cincinnati, at Lawrenceburg, Ind., about May 3.

Lieut. McIver Woody, M. R. C., U. S. Army, Boston, to Miss Regina Llewellyn Jones of Chestnut Hill, recently.

Asst. Surg. Lieut. Rudolph Heym, Jr., [illegible] U. S. Navy, to Miss Mary DeWeese, both of Cleveland, May 2.

P[illegible] Hunsicker, to Miss [illegible] B[illegible]w, Pa., at Allentown, Pa., [illegible]

Deaths

Lieut. John Paul Rosenwald, M. C., Minn. N. G., Minneapolis; John A. Creighton Medical College, Omaha, in 1910; aged 33; a Fellow of the American Medical Association; March 26 he received the Distinguished Service Cross, given by the French government on account of services rendered during the fighting on the Luneville sector; twice entered a battery position under heavy fire in order properly to care for the wounded; killed by shellfire in the Luneville sector, about May, 1918.

Paul Nathan Litchfield, Camden, N. J.; Jefferson Medical College, Philadelphia, 1895; aged 44; formerly a member of the New Jersey House of Assembly; formerly coroner of Camden; a member of the staff of the Tuberculosis Hospital at Ancora, and the County Hospital for the Insane at Blackwood; died at his home, May 1, from pneumonia.

William Beverley Pettit, New Canton, Va.; University of Maryland, 1883; aged 64; formerly a Fellow of the American Medical Association; a member of the Medical Society of Virginia; formerly surgeon at the Richmond Plant of the American Locomotive Company; died, April 27, from a gunshot wound, self-inflicted, it is believed.

Frank Judson Bardwell, Tunkhannock, Pa.; Yale University, Medical Department, New Haven, Conn., 1891; aged 49; a Fellow of the American Medical Association; formerly president of the Tunkhannock Board of Health; died at the Robert Packer Hospital, Sayre, Pa., April 12, from empyema of the gallbladder.

Frederick Blume, Pittsburgh; University of Gottingen, Germany, 1896; aged 68; a member of the Medical Society of the State of Pennsylvania; a member of the American Association of Obstetricians and Gynecologists; a member of the medical staff of the Allegheny General Hospital; died at his home, April 14.

Lieut. John Deming Arnett, M. R. C., U. S. Army, Albany, N. Y.; Albany (N. Y.) Medical College, 1914; aged 29; a Fellow of the American Medical Association; on duty with the Ninety-Ninth Field Ambulance, British Royal Army Medical Corps, on the French front; was killed in action, April 16.

Walter Sewell Wheeler, Kansas City, Mo.; Jefferson Medical College, Philadelphia, 1885; aged 57; a member of the Missouri State Medical Society; for many years city health commissioner, and professor of therapeutics in the University Medical College of Kansas City; died at his home, April 24.

John Nicholas Helmke, Louisville, Ky.; University of Louisville, Medical Department, 1873; Hospital College of Medicine, Central University, Louisville, 1875; aged 83; also a druggist; a veteran of the Civil War; died at his home, April 19, from bronchial pneumonia.

Frederick B. Kobisk, Lombard, Ill.; Jenner Medical College, Chicago, 1906; aged 39; formerly a Fellow of the American Medical Association; a member of the Illinois State Medical Society; was instantly killed, April 25, when a train crashed into his automobile.

Charles Orville Bechtol, Marion, Ind.; University of Illinois, College of Physicians and Surgeon, 1901; aged 43; a Fellow of the American Medical Association; died at his home, April 21, from paralysis, resulting, it is said, from the effects of ptomain poisoning.

Reuben Gardner Moore, Vincennes, Ind.; Cincinnati College of Medicine and Surgery, 1861; aged 81; also a pharmacist; formerly president of the board of trustees of Vincennes University; died at his home in Burnett Heights, April 23, from cerebral hemorrhage.

Peter Thompson Kilgour, Cincinnati, Ohio; Pulte Medical College Hospital, Cincinnati, 1892; aged 57; dermatologist to the Home of the Friendless, Cincinnati; died suddenly as he was entering the Mount Healthy M. E. Church, April 24, from cerebral hemorrhage.

Capt. Clement Edwin Laws, M. R. C., U. S. Army, Tacoma, Wash.; Medical College of Ohio, University of Cincinnati, 1899; aged 36; a Fellow of the American Medical Association; on duty at Camp Dodge; died in a local hospital, April 21, from spinal meningitis.

Albert Le Roy Fisher, Elkhart, Ind.; Hahnemann Medical College and Hospital, Philadelphia, 1871; aged 72; formerly a member of the Indiana State Medical Association; died at his home, suddenly, April 23, from cerebral hemorrhage.

Dwight Welcome Dryer, LaGrange, Ind.; Rush Medical College, Chicago, 1885; aged 61; formerly a Fellow of the American Medical Association; a member of the Indiana State Medical Association; formerly health officer of LaGrange County; died at the home of his daughter, April 25.

Adam H. McCullough, Mansfield, Ohio; Jefferson Medical College, Philadelphia, 1875; aged 67; a Fellow of the American Medical Association; surgeon of the Erie Railroad Company, also a druggist; died at his home, April 20, from pernicious anemia.

John Alexander Galbreath, Pottstown, Pa.; University of Pennsylvania, Philadelphia, 1911; aged 33; a Fellow of the American Medical Association; died at the home of his mother in Lansdowne, Pa., April 13, from pneumonia.

Gideon A. Embry, Irvine, Ky.; Jefferson Medical College, 1867; aged 79; a member of the Kentucky State Medical Association; secretary of the Estill County Medical Society; died at his home, February 5, from senile debility.

James E. Henderson, Springfield, Ill.; Northwestern University Medical School, 1883; aged 62; a colored practitioner; was found dead in his office, April 12, from gunshot wound, self-inflicted, it is believed, with suicidal intent.

Charles Edward Lee, St. Paul; Columbia University, College of Physicians and Surgeons, 1866; aged 76; formerly a member of the Minnesota State Medical Association; died suddenly at his office in Los Angeles, April 23.

John Fred Cleveland, Le Roy, N. Y.; Bellevue Hospital Medical College, New York City, 1865; aged 86; a member of the Medical Society of the State of New York; a veteran of the Civil War; died at his home, April 16.

Frank Grove McKelveen, Denver; Western Pennsylvania Medical College, Pittsburgh, 1892; aged 49; a member of the Colorado State Medical Society; died in St. Anthony's Hospital, April 21, from pneumonia.

Elmer E. Barton, Lafayette, Ind.; University of Wooster, Medical Department, Cleveland, 1878; aged 67; for many years engaged in historical writing; died in a sanatorium in Lafayette, April 18, from Bright's disease.

Warren Newell, Okmulgee, Okla.; Starling Medical College, Columbus, 1888; aged 54; formerly a member of the Oklahoma State Medical Association; formerly a practitioner of Idaho; died at his home, April 13.

Gabriel H. Watkins, Hollow Rock, Tenn.; University of Tennessee, Nashville, 1877; aged 72; formerly a Fellow of the American Medical Association; a veteran of the Civil War; died in Clear Water, Fla., April 13.

Oscar H. Rockwell, Monroeton, Pa.; University of Pennsylvania, Philadelphia, 1873; aged 74; a member of the Medical Society of the State of Pennsylvania; died suddenly at his home, April 16, from paralysis.

George Frederick Brooks, New York; University Medical College, New York, 1880; aged 59; a Fellow of the American Medical Association; and the New York Academy of Medicine; died at his home, April 26.

James W. Wideman, Due West, S. C.; Medical College of the State of South Carolina, Charleston, 1873; formerly a member of the South Carolina Medical Association; a veteran of the Civil War; died, April 17.

William B. A. McNutt, Monroe City, Mo.; St. Louis Medical College, 1875; aged 67; formerly a Fellow of the American Medical Association; died at the Missouri Baptist Sanitarium, St. Louis, April 10.

Thomas P. Guilfoyle, Cherry, Ill.; Northwestern University, Medical School, Chicago, 1903; aged 40; a Fellow of the American Medical Association; died suddenly at his home, April 18, from embolism.

Clark Leon Cain, Elmwood, Wis.; University of Illinois, College of Physicians and Surgeons, 1902; aged 39; a Fellow of the American Medical Association; died suddenly, April 18, from heart disease.

William H. Woodruff, Moundsville, W. Va. (license, West Virginia, act of 1881); aged 64; a member of the West Virginia State Medical Association; died at his home, April 21, from pneumonia.

George Davis Fyfe, Jersey City, N. J.; New York University, New York, 1896; aged 47; a Fellow of the American Medical Association; died at his home, April 27, from pneumonia.

William Winfield Nelson, Richmond, Va.; University College of Medicine, Richmond, 1901; aged 38; a member of the Medical Society of Virginia; died at his home, about April 29.

Vance May, Washington, Ind.; University of Louisville, Medical Department, 1894; aged 51; a member of the Indiana State Medical Association; died at his home, January 19, from pneumonia.

Lillian Gertrude Towslee, Cleveland; Cleveland College of Physicians and Surgeons, 1888; aged 57; a Fellow of the American Medical Association; died at her home, April 22, from pneumonia.

Weems R. Winchester, Macon, Ga.; University of Maryland, Baltimore, 1874; aged 69; formerly a Fellow of the American Medical Association; died at his home, April 16, from paralysis.

John Shattuck, Irontown, Ohio; Miami Medical College, Cincinnati, 1872; aged 69; formerly a member of the Ohio State Medical Association; died at his home, April 15, from heart disease.

Robert J. Black, McKeesport, Pa.; College of Physicians and Surgeons, Baltimore, 1881; formerly mayor of McKeesport; died in the McKeesport Hospital, April 27, from heart disease.

James Lee Phillips, Providence, R. I.; Harvard University Medical School, 1892; aged 53; a Fellow of the American Medical Association; died at his home, about April 22.

Judson A. Butts, Brunswick, Ga.; Jefferson Medical College, 1860; aged 88; formerly a member of the Medical Association of Georgia; died at his home, April 18.

Henry L. Barnes, Ripon, Wis.; Western Reserve University, School of Medicine, Cleveland, 1858; aged 83; a veteran of the Civil War; died at his home, April 26.

Joseph Sherman Adsit, Hoopeston, Ill.; Chicago Homeopathic Medical College, 1891; aged 50; a member of the Illinois State Medical Society; died, April 1.

Ernest Janes McCampbell, Kansas City, Mo.; Kansas Medical College of Topeka, 1908; aged 29; a colored practitioner; died, March 28, from pneumonia.

Julius Adolar Winter, Brooklyn; Long Island College Hospital, Brooklyn, 1888; physician of the Panama Steamship Company; died at his home, April 23.

Charlotte Kent Bailey, Lyons, Ill.; Bennett Medical College, Chicago, 1910; aged 40; fell from the second story porch at her home, April 29, and was killed.

Frederick J. Weber, Highlandtown, Md.; Baltimore Medical College, 1908; Atlantic Medical College, Baltimore, 1909; aged 30; died at his home, April 16.

William Thomas Ellison, Bedford, Ind.; Bellevue Hospital Medical College, New York City, 1875; aged 68; died at his home, April 15, from heart disease.

Edwin Parsons Clark, The Plains, Va.; University of Pennsylvania, Philadelphia, 1858; aged 84; a veteran of the Civil War; died at his home, April 14.

Nicholas Dennis Richards, Belleville, Ont.; University of Toronto Faculty of Medicine, 1877; aged 65; died at his home, April 19, from heart disease.

George F. Broun, Nashville, Tenn.; University of Virginia, Medical Department, Charlottesville, 1892; aged 44; died, April 4, from tuberculosis.

Walter Scott Goodhue, Kansas City, Mo.; Hahnemann Medical College and Hospital, Philadelphia, 1872; aged 71; died at his home, April 22.

Ripley Ezra Woodard, Little Rock, Ark.; Vanderbilt University, School of Medicine, Nashville, 1890; aged 52; died at his home, April 22.

Edgar Snyder, Edgewater, Colo.; Rush Medical College, Chicago, 1876; aged 69; died at St. Anthony's Hospital, Denver, April 17.

John Williams Bosworth, Boston; Boston University, School of Medicine, 1876; died at his home, in Rosendale, about April 6.

Eli H. Thurston, Hagerstown, Ind. (license, Indiana, 1897); aged 69; died at his home, April 16, from heart disease.

Clinton O. Shrader, Bowling Green, Ohio; Eclectic Medical Institute, Cincinnati, 1902; aged 43; died at his home, April 9.

William G. Caron, Aurora, Ill.; Rush Medical College, 1897; aged 44; died at his home, April 22, from pneumonia.

Luther R. Wright, Sulphur Rock, Ark. (license, Arkansas, 1903); aged 44; died at his home, April 7.

W. H. McCall, Briggsville, Ark. (license, Arkansas, 1903); aged 74; died at his home, April 23.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION

SYPHILODOL

Report of the American Medical Association Chemical Laboratory

The shortage of arsphenamin (salvarsan) has made the sale of substitutes a profitable business. In many of these substitutes the earmarks of dishonesty have been obvious, so that detection of their falsity was relatively simple. In the case of "Syphilodol" marketed by the French Medicinal Company, Inc., New York, the deception has been practiced more skilfully. In the circular announcing their preparations, we read:

> "It seems fitting at this time, when the American physicians are doing so much for France, that there should be a reciprocation in some way.
>
> "Attempting to enhance somewhat this mutual interchange, we are presenting some of those scientific products, which have been so successfully used in France.——"
>
> "The effect of SYPHILODOL is very similar to salvarsan and neosalvarsan, but it has the advantage of being more lasting in its results and more pleasing in the manner of its preparations, in that it is put up in the form of tablets, and, also, in hermetically closed glass syringes or ampules, so that it may be administered either by the mouth, intravenously or intramuscularly, at the discretion of the physician. Patients averse to the use of the hypodermic needle may be treated expeditiously by the use of the tablet form of the medicine."

In addition to Syphilodol, the French Medicinal Co. also sell "Vichy Fruti," a combination of salts, "Urodol," an "alkaline salt of the famous European Springs which is noted for breaking up and dissolving uric acid rapidly" and "Syloiodol," "French Preventive" which is described as "a solution of iodol incorporated into bougie."

"Syphilodol," we are told, is "a synthetic chemical product of *silver, arsenic* and *antimony*, scientifically prepared after the formula of the *late* Dr. Alfred Fournier of Paris." (Italics ours—Ed.). It is also claimed that "Prof. Metchnikoff and other noted French Scientists have made exhaustive tests of syphilodol and found it superior to the other products, in the treatment of syphilis." In the advertisements, Fournier and Metchnikoff are the only names given of alleged endorsers; both of these men are dead and cannot protest. True, Fournier did considerable work on a legitimate synthetic of antimony, silver and arsenic having a general chemical constitution similar to arsphenamin, but so far as we are aware, there has been no publication by these men on "Syphilodol." It would seem that the valuable work and high reputation of Fournier and Metchnikoff are being capitalized by the French Medicinal Company in their endeavor to foist a nostrum on the medical profession of this country.

"Syphilodol" comes in two forms—ampules and tablets. An order for two 0.4 ampules brought an elaborate case, much like those used to hold the popular style safety razors. The ampule itself was a "classy" affair evidently made by a glass expert; the hypodermic needle was enclosed in a novel sealed glass device. The price of each ampule is $3. No such fancy garnishments came with the tablets, although they are listed at $4.50 for twenty-five—18 cents a tablet! In the "Syphilodol" advertising it is emphasized that both the tablets and ampules are to be administered. For example:

> "Syphilodol is dispensed in the form of tablets and also in hermetically closed glass syringes or ampules so that it may be used either by the mouth, intravenously or intramuscularly at the discretion of the physician. An advantage of the tablets is that they can and should be given during the interim between the injections."

LABORATORY REPORT ON SYPHILODOL

Several samples of "Syphilodol" were sent to the Amer Medical Association Chemical Laboratory by readers o JOURNAL. An original bottle of tablets was orde from the French Medicinal Company

25 yellow tablets, having an average weight of 0.276 gm. (4 ¼ grains). After being powdered, "Syphilodol" was found to be only partially soluble in water (the excipient is soluble) and to be neutral in reaction. These findings contradict the claims on the circular accompanying the bottle to the effect that "Syphilodol is a yellow powder, soluble in water, and has an acid reaction." Qualitative tests indicated the presence of mercury, sucrose (cane sugar), iodid, calcium, sulphate, fatty material, a trace of silver, a trace of arsenic and a very minute trace of antimony; a red dye was also present. Both qualitative and quantitative data showed that the mercury was present in the form of mercurous iodid (yellow iodid of mercury—*hydrargyri iodidum flavum*). Quantitative estimations yielded the following:

Silver (Ag^+)	0.001	per cent.
Mercury (Hg^+)	11.1	per cent.
Iodid (I^-)	7.8	per cent.
Sucrose (Cane sugar)	72.0	per cent.
Ash (Calcium Sulphate)	2.5	per cent.
Ether-soluble material (Fatty material—Petrolatum)	3.5	per cent.

Thus each tablet of "Syphilodol" contains approximately ¾ grain of mercurous iodid. An ampule of "Syphilodol," labeled 0.4 gram, contained approximately 1.5 c.c. of a liquid which after evaporation on a water-bath left a residue weighing 0.8 mg., or 1/80 grain. A second ampule held about 2 c.c. of liquid, which contained a trace of arsenic (less than 0.00001 gm., or 1/6000 grain); a very small amount of mercury was indicated but not definitely established. The liquid had the physical characteristics of water.

Accompanying "Syphilodol" advertising sent to physicians is a circular letter inviting the doctor to become a member in the "United States Bacteriological and Research Institute." The "institute" seems to be a means of suggesting that the physician have bacteriologic, pathologic and serologic examinations made on behalf of his patients. In view of the fact that it is to the commercial interest of the French Medicinal Company to have as many users of "Syphilodol" as possible, it would be interesting to know what proportion of the Wassermann tests are reported negative.

Shorn of its mystery, Syphilodol the "synthetic chemical product of silver, arsenic and antimony" is essentially mercurous iodid—yellow iodid of mercury.

PYOCYANEUS BACILLUS VACCINE OMITTED FROM N. N. R.

Report of the Council on Pharmacy and Chemistry

The Council has authorized publication of the following report. W. A. Puckner, Secretary.

Pyocyaneus bacillus vaccine, made from *Bacillus pyocyaneus*, was admitted to New and Nonofficial Remedies in 1910. At that time this vaccine was considered to give promise of having therapeutic value.

Now three of the firms whose preparations of this vaccine are described in New and Nonofficial Remedies advise the Council that they have ceased to manufacture the vaccine because of lack of demand. The fourth firm stated that in the printing of a new list of its biologic products, pyocyaneus vaccine would not be included, and that the preparation would be supplied on demand only.

The referee of the Committee on Serums and Vaccines in charge of pyocyaneus bacillus vaccine held that the discontinuance of the preparation by interested firms, for the reason that there was no demand for it, evidences that it had been proved without value. He reported that a search of recent literature failed to reveal any evidence of its usefulness.

On the recommendation of the referee, the Council directed that the several preparations of the vaccine be omitted from New and Nonofficial Remedies.

Child Hygiene.—When, in addition to our attention to the welfare of infants, we devote greater interest and more earnest efforts to the hygiene of children between the second and fifth years of life, the beneficent effect will soon be indicated in the falling death rate of the whole community.—*Public Health* (Mich.).

Correspondence

A METHOD FOR DECOLORIZING AND STAINING BLOOD FILMS

To the Editor:—Having to make and examine many blood films in the course of our routine work (1,163 in 1917) we found it somewhat of a problem to make Arneth and differential counts, study the morphology of the cells and look for malaria at the same time, with fair assurance that, if present, the malarial parasite could be found while counting and examining 100 or 200 white cells.

Mr. G. E. Burke, C.E., F.R.M.S., who was my co-worker in the blood laboratory, discovered a quick method of decolorizing the unstained films, which, combined with my staining methods, gave us a specimen, in half of which the red cells had disappeared, but the leukocytes, platelets, nuclei, etc., were brought out sharply, and apparently improved in staining qualities; and the other half of which was as of an ordinary smear, and was used for studying the red cells. Our method gives uniformity of results, freedom from precipitates and artefacts, lack of "messiness" and great time saving, and is as follows:

The blood smear is made on a slide, but, preferably, one that is drawn out to extreme thinness, and allowed to dry. It is not fixed.

The lower half of the smear is covered with the clean slide, strong pressure being employed to exclude air, and the exposed half of the blood smear is breathed on heavily. This is repeated if necessary. Where the breath comes in contact with the film, the red cells disappear.

The slide is immersed from thirty seconds to three minutes in stain, transferred to water in a Coplin jar from one minute to three minutes, washed ten seconds in the clear distilled water, and stood upright to dry, or blotted. The same water may be used repeatedly, and eight slides at a time stained.

Being a layman I cannot, of course, speak with much authority on such matters; but Mr. Burke and I would be pleased to learn if this method has been used before, and with what success. If it has not been used before, we think it is worth trying out, especially in malaria. We have had uniform success with the method in ordinary blood work so far. What happens to the erythrocytes when breathed on that they should disappear?

F. W. Lacy, F.R.M.S., Fort Lyon, Colo.

"SERUM DIAGNOSIS OF SYPHILIS"

To the Editor:—Permit me to voice a protest against the adoption by Army and Navy laboratories of the method of performing the Wassermann test proposed by Dr. Hideyo Noguchi in The Journal, April 20, 1918. This method is open to a number of sources of error which would on the one hand tend to brand innocent men with the stigma of syphilis, and on the other cause cases of syphilis to escape detection which could be detected by more exact methods. I think the matter of sufficient importance to request the space necessary to point out these sources of error.

In every complement fixation test the complement acts as a unit of measurement by which the fixing power of a serum under examination is measured. It must be apparent even to the uninitiated that this measuring unit must be a known quantity in order that it may be effectively used as a standard by which to measure an unknown quantity. Wassermann, realizing this, selected guinea-pig serum as the source of complement because its complement content was more uniform than that of any other animal he had examined. In recent years careful workers (compare Ottenberg: On the Reliability of the Wassermann Reaction, *Arch. Int. Med.*, March, 1917, p. 457) have come to the conclusion that even guinea-pig serum varied so much in complement content as to introduce an inexcusable source of error. Dr. Noguchi himself (Noguchi and Bronfenbrenner: Variations in the Complement Content and Fixability of *Guinea-Pig Serum,*

human serums tested by the Wassermann reaction, is such that a negative reaction can result when there are less than eight antibody units, so that when the native complement has been removed by inactivation and accurately titrated guinea-pig complement added, this unknown and uncontrollable factor of natural antisheep amboceptor undoes the previous adjustment. It is clear, therefore, that the degree of hemolysis is an index neither to the absolute content of complement nor of amboceptor, but only of the combined effect of both in various proportions. One hundred per cent. hemolysis may express the interaction of 0.1 c.c. of guinea-pig complement and 0.00006 c.c. of amboceptor, or of 0.01 c.c. of the former and 0.0012 c.c. of the latter, that is, one complement unit and one amboceptor unit or one tenth of a complement unit and twenty amboceptor units. There will be as many combinations as there are divisible fractions within the range of activity of the complement and the amboceptor. The hemolytic effect of complement is proportionately enhanced, as the amount of amboceptor is increased, to a point at which the former cannot be augmented. The Wassermann system (antisheep hemolytic system), then, is not a quantitatively accurate method, no matter how accurate the titration of guinea-pig complement and immune antisheep amboceptor, since the relative quantities of complement, amboceptor and corpuscles are, in the final result, unknown, being no longer adjusted to produce a uniform hemolytic system.

The effect of an excess of amboceptor in the fixation reaction is more disturbing and far reaching than that of a narrow variation in complement, when the latter is combined with a known definite quantity of amboceptor. A negative reaction, or a weak instead of a strong positive one, is more apt to result from the excess of amboceptor naturally present in the Wassermann system than from the excess of complement occurring in a few human serums, since in the former case a negative reaction may result if the serum contains less than eight antibody units, whereas in the latter a positive reaction cannot be masked even when the serum contains only two antibody units.

Let us now analyze the results obtained with a serum whose complement activity is below the average. I have recommended the additional amboceptor for those specimens in which hemolysis is incomplete within thirty minutes, because by this means the same hemolytic effect (complete hemolysis in the control) can be secured as is obtained by the combination of the average complement content and one amboceptor unit. To such a procedure I fail to see any objection. As for those serums which have no complement, or too little to produce complete hemolysis, even with additional amboceptor, it has been recommended that 0.1 c.c. (up to 0.2 c.c.) of the serum be mixed with 0.1 c.c. of fresh active nonsyphilitic human serum. Clearly, the test here corresponds with that of a specimen containing the same amount of antibody and one complement unit plus the fraction of a unit naturally present in the serum. The addition of 0.1 c.c. of a negative serum to 0.1 c.c. (up to 0.2 c.c.) of a serum deficient in complement no more affects the sensitiveness of the fixation reaction than does the addition in the Wassermann test of 0.1 c.c. of guinea-pig serum to 0.2 c.c. of inactivated serum. In fact, since the antibody content of 0.1 c.c. of an active human serum is from four to five times that of the same serum when inactivated, the source of interference from the introduction of 0.1 c.c. of active serum is more than taken care of by the intact antibody content.

By actual experiment I have found that when working with the antihuman system, whether guinea-pig or human complement is used, the addition of an inactivated negative human serum (0.1-0.4 c.c.) to any amount of syphilitic antibody representing more than one half the antibody unit has no weakening effect on the reaction. A minute amount of a positive syphilitic serum (0.006 c.c. for example), when mixed with 0.1-0.4 c.c. of inactivated negative serum and then supplemented with 0.1 c.c. of fresh negative human as complement gives just as strong reaction as when no negative serum has been added. Dr. Seelman quotes my earlier observation with Bronfenbrenner regarding a possible complementoid blocking of fixation, but he appears to overlook the fact that the phenomenon was found to apply mainly to certain animal serums (guinea-pig, chicken, etc.), human serum having shown the least interference. The interference is noticeable when a quantity of negative serum as large as 0.3-0.4 c.c. is used with a very small fraction of the antibody unit (less than one half), but there is none with 0.1-0.2 c.c. In the proposed test, therefore, this source of masking a positive reaction does not exist, as any serologist can demonstrate for himself. The observations of Sellards and Minot, it should be noted, apply only to the antisheep hemolytic system. A serum deficient in complement can be used in a dose of 0.2 c.c. and may be supplemented by a negative human serum in a dose representing one complement unit (0.1 c.c. or more) without danger of masking a positive reaction.

Dr. Seelman's reference to a possible false positive reaction from an excess of "indifferent fixing protein substances" in the mixture of inactivated patient's serum (0.2 c.c.) and negative human serum as complement (0.1 c.c.) seems to be without practical or theoretical basis. If, however, Dr. Seelman refers to the anticomplementary property of the inactivated serum, the answer is that if the added human complement is insufficient to bring about complete hemolysis in the control tube, the test is of course repeated with a sufficient amount of complement. Hemolysis must of course be completed satisfactorily in the control tube before the result is read, in this as in any other fixation method. One occasionally encounters anticomplementary serums, it is well known, and they are handled accordingly, whether one is using the Wassermann antisheep system or the antihuman system, that is, the serum is heated to 55 degrees C. for fifteen minutes to remove its anticomplementary property, or more complement is used, or the amount of the serum is reduced to a noninhibitory quantity.

Dr. Seelman's assumption that a serum containing a subnormal amount of complement should cause a false positive reaction does not apply to the proposed system, as the antigens used in the latter have no anticomplementary property. The antigens used in the Wassermann system, however, consist of either an alcoholic extract of heart, syphilitic liver, or heart extract plus cholesterin (Sachs, Fildes and McIntosh), all of which possess a pronounced anticomplementary property. It has never been defined how small a quantity of a suitable extract should be able to fix complement with a syphilitic serum, the only requirement being that the highest antigen dose should be one half the amount which completely fixes complement without the syphilitic antibody. If the amount of complement were deficient in a system in which such an antigen is used, a false positive reaction would of course result, since half of the complement is taken up by the antigen. The antigen which I recommend, both for the old antihuman hemolytic system and for the proposed system is, however, free from those constituents which impart to the alcoholic extracts their anticomplementary and hemolytic properties and their property of nonspecific reaction with active serum, and it consists of a pure acetone-insoluble fraction of tissue lipoids. The standards that I have set for a suitable antigen are as follows: The acetone-insoluble lipoids are kept in absolute methyl alcohol as a 3 per cent. solution, one part of which is mixed with nine parts of 0.9 per cent. saline solution. The opalescent fluid is then tested for its hemolytic, anticomplementary and antigenic titers. If it causes hemolysis or inhibits the action of complement in a dose of 0.4 c.c. in a total of 1 c.c., the preparation is rejected. If it is satisfactory in this respect, however, it is tested for its antigenic property with strongly positive serums, and only those preparations which produce complete fixation in a dose of 0.02 c.c. are regarded as suitable. One-tenth c.c. (at least five antigenic units) is used for the test. The antigen preparations used in our laboratories often contain as many as 200 antigenic units in 0.1 c.c. Although the antigen selected according to the standards described is highly active, no nonspecific fixation results even from the use of an excessive dose (within 0.1 c.c.) with active serums. The anticomplementary property of antigen against different guinea-pig or human serums as a source of error causing a

COMMUTATION, INCOME, INSURANCE AND EXPENSES OF MEDICAL RESERVE CORPS OFFICERS

To the Editor:—1. What allowance is made by the government for a first lieutenant's wife, there being no children? 2. What would be the gross income for such an officer having a wife and no children? 3. What is the increase in salary for foreign service? Would the allowance for the wife be granted when the officer is on foreign soil, or when he is so located that his wife cannot spend her time with him? 4. What provision is made for insurance? 5. Can you give the approximate cost of a first lieutenant's living expenses while on active duty?

W. D. Gilmore, M.D., Mooresville, N. C.

Answer.—1. Commutation for a first lieutenant who maintains a residence for a dependent would approximate from $40 to $50 per month.

2. From $2,400 to $2,500.

3. Ten per cent. The question of commutation for officers on foreign service—that is, whether they receive single or double commutation—has not yet been determined by the comptroller.

4. Officers are covered by the Federal War Risk Insurance, the cost varying according to the age of the officer and the amount of insurance taken; $10,000 worth of insurance may be carried for from $6.50 to $8.10 per month for the ages between 20 and 40.

5. The living expenses vary from $40 up.

ELIGIBILITY FOR ADMISSION TO THE MEDICAL RESERVE CORPS—COMMISSIONS IN THE ALLIED ARMIES

To the Editor:—1. Please advise me whether I am eligible for a commission in the United States Army (Medical Reserve Corps)? I was born in England, but have been in this country since I was 3 years of age. Through mistake I have never taken out naturalization papers. 2. What steps would it be necessary to take in order to get an appointment or commission in the Canadian or British army as a physician? Any information you may be able to give as to rank, pay, etc., in the latter armies will be appreciated.

H. R. B.

Answer.—1. Since you are not a naturalized citizen, you are not eligible for a commission in the Medical Reserve Corps of the United States Army.

2. Both the British and Canadian armies have representatives in all the large cities of this country. Information may also be obtained by addressing the Surgeon-General, Department of Militia, Ottawa, Canada.

COMMISSIONS IN THE MEDICAL RESERVE CORPS AND IN THE MEDICAL CORPS, NATIONAL ARMY

To the Editor:—1. How can a commissioned officer in the Medical Reserve Corps transfer or get a commission in the Medical Corps, National Army? 2. What advantages or privileges does a commission in the Medical Corps, National Army, give the holder over a commission in the Medical Reserve Corps?

Henry C. Woltman, Major, Camp Pike, Ark.

Answer.—1. By appointment by the President on recommendation of the Surgeon-General.

2. None except such as go with higher rank if appointed to such rank.

PAY OF OFFICERS OF THE MEDICAL RESERVE CORPS

To the Editor:—What pay do medical reserve officers receive?

A. R. Remley, M.D., Lawson, Mo.

Answer.—Annually: First lieutenant, $2,000; captain, $2,400; major, $3,000; commutation for quarters: lieutenant, $432; captain, $576; major, $720; heat and light: approximately $80, $120 and $160, respectively. The increase in pay for foreign service is 10 per cent.

STATE LICENSING BOARDS AND MEDICAL RESERVE CORPS OFFICERS

To the Editor:—What states will grant license without further examination to officers in the Medical Reserve Corps? Will this continue after the war is over?

W. Y., M.D., Linden, Tenn.

Answer.—None.

Wisconsin: Milwaukee, June 25. Sec., Dr. J. M. Dodd, Ashland.

British Medical Students and the Army

The *Medical Press,* London, states that a national service instruction has just been issued under which it is provided:

1. That a medical student who is a full-time student at a recognized medical school, who has passed his first professional examination in chemistry, botany and zoology, is not to be called up, whatever his medical category or trade, so long as he remains a full-time medical student.

2. A full-time medical student at a recognized medical school, who produces a certificate from the dean of the faculty that he should be able to pass his first professional examination on or before July 31, is not to be called to the colors before July 31.

3. A medical student protected under this instruction, who does not, within thirty-six months of the date of commencing his professional studies, pass his professional examinations in anatomy and physiology, will forthwith be called to the colors if otherwise available, and required for service.

4. In order to be entitled to the protection under the instruction, a medical student must enrol in an officers' training corps for medical cadets.

5. Protection under the instruction will be withdrawn from any medical student who has been requested, in writing, by the ministry of national service, to offer his services as a surgeon probationer in the navy, and who has not within twenty-one days thereafter sent an application for enrolment as a surgeon probationer.

Other provisions apply to medical students in categories B and C, and for the review of all cases where students are protected from military service.

Oregon January Examination

Dr. Herbert Nichols, secretary of the Oregon State Board of Medical Examiners, reports the written examination held at Portland, Jan. 2-4, 1918. The examination covered 10 subjects. An average of 75 per cent. was required to pass. Of the 24 candidates examined, 15, including 1 osteopath, passed, and 9, including 3 osteopaths, failed. The following colleges were represented:

Book Notices

The Future of the Disabled Soldier. By C. W. Hutt, M.A., M.D., D.P.H., Oxford, Deputy Medical Officer of Health County Borough of Brighton. Cloth. Price, $2. Pp. 199, with 14 illustrations. New York: William Wood & Co., 1917.

Many physicians and laymen in this country are keenly alive to the problem that will soon be confronting us as to how best to fit the disabled soldier to do what work he can. The government, as is known, is making preparations to care for and train these unfortunates. To all those interested in this question Hutt's book can be recommended as containing in small compass a dependable statement of the aims and requirements of such work, and what has already been done in other countries than ours. The book is authoritative, scientific and not sentimental; it is inspiring. One rises from reading it, determined not only to do what one can in helping the disabled soldier but also to try to assist all those physically unfit either by youth, old age, disease or accident to find occupation suited to their capacity.

Electro-Therapy in Gynaecology. By Samuel Sloan, M.D., F.R.F.P.S.G., Consulting Physician to the Glasgow Royal Maternity and Women's Hospital. Cloth. Price, $4. Pp. 298, with 59 illustrations. New York: Paul B. Hoeber, 1918.

The venerable author presents this book not as a textbook in electrotherapeutics or in gynecology, but as a record of his own work during the last twenty years in electrotherapy as applied to gynecology. He believes that electrotherapy is of value in medical or nonoperative pelvic affections. Formerly it was almost entirely empiric and somewhat unsatisfactory, so that it came to be neglected. The author considers that it has now been established on a scientific basis. The first part is devoted to an elementary presentation of electrophysics. In the second part, the electromedical apparatus is described. In the third part, the principles of electrotherapy, and the action of static, galvanic, alternating and high frequency currents are discussed. Constitutional diseases, mostly functional, to which women especially are liable, are then considered, and the great value of electrotherapy is shown. In the fifth part, devoted to pelvic affections, neuroses of the pelvic structure are found to be especially benefited by electrotherapy. Here the author is in agreement with those gynecologists who have not entirely neglected all kinds of therapy except the operative. In the chapter on sepsis and pelvic inflammation, he comes more in conflict with the usual professional opinion, for he finds that here there is absolute assurance of success. Numerous illustrations give a good idea of the apparatus and technic of his method of ionization for septic disease. Not so much weight is laid on the electric treatment of fibroids, the proper field for which is the accompanying pain and hemorrhage. He does not discuss roentgen therapy. In the appendix are given in tabular form brief abstracts of the histories of 212 cases on which the work is based. Electrotherapy in gynecologic practice has become nearly obsolete in this country. The high reputation of the author and his conservative, modest presentation of the subject may well lead the profession to study anew the possibilities of a nonmutilating therapeutic agent.

Manual of Splints and Appliances for the Medical Department of the United States Army. Report of a Board Convened for the Purpose of Standardizing Certain Medical Department Supplies: Lieut.-Col. William L. Keller, M. C.; Major Robert B. Osgood, M. R. C.; Major Alexander Lambert, M. R. C.; Major Joseph A. Blake, M. R. C.; Capt. W. S. Baer, M. R. C., and Capt. Nathaniel Allison, M. R. C. Cloth. Price, 75 cents net. Pp. 208, with 173 illustrations. New York: Oxford University Press, 1917.

This manual is the outcome of the report of a board convened for the purpose of standardizing certain medical department supplies under Special Order 73, A. E. F., Aug. 20, 1917. As it is of notebook size (about 4 by 6 inches), it may be slipped into the pocket, ready for instant reference at all times, by the Army surgeon. It epitomizes the subject of splints, appliances and dressings. In determining the character of the standard appliances to be employed, efficiency, correct mechanical principles, simplicity of design, low cost of construction, and transportability were the chief considerations. The manual is in four parts. Part 1 covers general considerations and detailed descriptions of splints and appliances recommended for use at field and evacuation hospitals. Part 2 relates to their use at base hospitals, where the practice is somewhat different. Part 3 covers surgical dressings and accessory supplies. Part 4 contains illustrations showing the exact application of the various splints, appliances and dressings in the multifarious injuries to bones and joints, as well as the accompanying lesions of the soft parts, which may occur in modern war. In leg and arm splints the Thomas wire traction splint with hinged and other modifications, the long interrupted Liston splint, thigh splints of the Hodgen and Cabot types, of the simplest construction, usually of wire, have been adopted. Simplicity in apparatus and brevity in the description of their uses and indications, with excellent illustrations of their practical application, making everything clearly understood, are the result of the deliberations of the board as shown in this well printed manual.

The Third and Fourth Generation. An Introduction to Heredity. By Elliot Rowland Downing, the School of Education, University of Chicago. Cloth. Price, $1 net. Pp. 164, with 13 illustrations. Chicago: University of Chicago Press, 1918.

This book is a plea for the application of a sane and practical eugenics, presented in simple, nontechnical language. It is addressed particularly to young people as students, because of their ready adaptibility to new facts and their freedom from the traditions and prejudices that hamper the older generation. To emphasize the important part the laws of heredity play in the development of the human race, the author draws an interesting parallel between certain highly pedigreed American race horses and superior families of gifted men like Johann Sebastian Bach and Charles Darwin, contrasting them with the evil strain of the famous, or infamous, Max-Jukes. The problems presented by the contrast, especially the problem of Nature's tendency to perpetuate undesirable as well as desirable traits, he then considers in the light of their relation to sexual reproduction. Mendel's law of the recurrence of dominant and of recessive traits in alternate generations is carefully explained in connection with the latter's famous experiments in plant breeding. Biologic evidence is brought to bear on the theory of the transmission of hereditary traits by means of the chromosomes in the living cells. The student learns that the much emphasized prenatal influence has little to do with hereditary characters of a plant or an animal, which are determined at the time of the fertilization of the egg. In applying these laws to the improvement of human stock, the author calls attention to the appallingly rapid growth of the feebleminded population in the United States, reviews the records of families tainted with insanity in every generation, and makes an appeal for the segregation of the feebleminded, in order to eliminate the mentally defective, criminal and degenerate stocks.

Medicolegal

Liability of Employer for Physician not Answering Call

(Owens v. Atlantic Coast Lumber Corporation (S. C.), 94 S. E. R. 15)

The Supreme Court of South Carolina reverses an order that sustained a demurrer to the plaintiff's complaint for damages for a breach of the defendant's contract to provide medical attention to his sick wife, for the lack of which she died. The court says that the complaint alleged that the plaintiff was an employee of the defendant; that the defendant deducted $1 from the monthly wages of each of its employees to maintain a staff of two physicians to render medical attention to them and their families when needed and requested; that the plaintiff called twice on one of the physicians, a Dr. Brown, who refused to give medical attention to the plaintiff's wife, on the pretext of being too busy and because he could not risk his automobile on a certain ferry; that the plaintiff could not find the other physician, and was without means to employ any one else, etc. The trial court took the view that the complaint showed affirmatively that the plaintiff had no cause of action, probably on the ground that the defendant was not liable for the action of the physician, in the absence of an allegation of its negligence in his selection. That was a misconception of the plaintiff's case. He did not seek to recover damages for the malpractice, negligence or unskilfulness of the physician in the management of the case after he took charge of it, but for the breach of the defendant's contractual duty, in his refusal to render any service at all.

It was too plain for argument that, under the facts alleged, there was a contract, and that it was based on a valuable consideration. The only real question was, Did the plaintiff allege enough to show a breach of that contract by the defendant? From the nature of the case, the plaintiff was bound to notify one of the physicians of his wife's need of attention, and, also, of her right to it, by reason of his being an employee, if that fact was unknown to the physician. While there was no direct allegation that Dr. Brown knew that the plaintiff was an employee, it was fairly inferable from all the facts alleged that he did, for he did not refuse the plaintiff's request on that ground, as he probably would have done, if he had conceived that the plaintiff's wife was not entitled to his services for that reason. The giving of other excuses impliedly excluded that one. At any rate, he should not have based his refusal on that ground, keeping it concealed, without inquiring of the plaintiff as to the truth of the matter. Besides, it was inferable from all the circumstances that these physicians were engaged chiefly, if not exclusively, to attend to the defendant's employees, which was enough to put the physician on inquiry which would have disclosed the fact.

The general rule is that notice to one who has been appointed by the master to perform his duty is notice to the master. So, too, as a general rule, a breach of contract that is due to the failure or inability of a third person with whom the party in default has made contracts to enable him to perform his contract does not excuse such breach. In this case the physician was the third person contracted with by the defendant to perform its part of the contract to provide medical attention to the plaintiff's wife. He was the defendant's agent for the performance of its contractual obligation to the plaintiff, and notice to him was notice to the defendant, and his failure to render any service at all was the defendant's failure to perform its contract.

While, in the view taken, the question of whether the defendant would be liable for the malpractice of physicians carefully chosen was not strictly within the issues tendered by the complaint, there is one view of the case in which that question might become important. If the deductions made resulted in direct pecuniary profit to the defendant, then, clearly, it would be responsible for the negligence or malpractice of the physicians employed even with due care, on the same principle that a private hospital conducted for gain, or the physician himself, is made liable.

Use of Liston Splint—Admissible Evidence

(Baldwin v. Baines (Vt.), 102 Atl. R. 338)

The Supreme Court of Vermont reverses, for retrial on the question of damages only, a judgment recovered by the plaintiff for malpractice in the treatment of a simple oblique fracture of the middle third of the right femur, because he was not only allowed, without sufficient evidence, to recover for what he had already lost in earning capacity, but the jury was permitted to speculate as to how his capacity to earn money would be affected in the future. The court says that a long splint, called a Liston splint, was used, and that when it was removed the leg was found to be 2¼ inches shorter than the other one, and the ends of the broken bone overlapped so that there was an angular deformity at the point of fracture.

The defendant excepted to the charge of the trial court wherein it allowed the jury to find the defendant negligent for using the Liston method rather than some other, insisting that on the evidence it was not permissible to find that this method did not accord with the degree of knowledge, care and skill that was exercised by physicians engaged in the same general line of practice in that neighborhood. But this exception could not be sustained. It assumed that the evidence was all one way on that phase of the case. It ignored the medical testimony tending to show that this method was obsolete; that it was not used by certain other physicians in that locality; that it would not insure complete fixation, and that it was inefficient in the matter of extension, unless the perineal band connected with it was constantly watched.

The defendant also excepted to the charge because it did not make clear to the jury that the defendant would not be liable if, in selecting a method of treatment, he chose one just as good as those generally recognized by the profession in that locality, even if it was not in general use there. What the court charged was that the defendant could not be held liable for a mere error of judgment in choosing from several well-recognized and authoritative methods of treatment the one he in fact used, and that he could not be held liable if the method chosen was a proper method and one well recognized in the same general neighborhood by those in the same general line of practice. So far as the criticism here made was concerned, the charge was all that the defendant was entitled to.

Another exception to the charge was predicated on the assumption that the court asked the jury to consider the question whether this leg was so put up that there could be no movement of the bones and no shortening of the leg. The language of the court was: "Was it in such a shape that it would hold those bones in apposition? Was it in such a condition that there would be no unnecessary shortening of the limb? Was the leg treated by the method with which it was treated in such a way that there could be no movement to the side?" This language did not make the defendant an insurer of a perfect result. It recognized that there might be some shortening of the limb without liability of the physician. It required a physician to set the leg and hold the bones in apposition, and to guard against crowding the bones sideways. The exception could not be sustained.

A physician, who testified that he had never used or seen a Liston splint, and knew nothing regarding the results of that method of treatment, was shown two roentgenographic plates, which were exhibits in the case, and was asked whether, assuming the plates were taken of the plaintiff's injured leg, the angular deformity shown was such as would be produced by bandaging the leg to this side splint as done by the defendant, and was allowed to answer that it was. This was not error, either as violating the rule forbidding the expression of an opinion on the question the jury was to decide or because the witness had never had experience with this method of treatment. It is not at all unusual to allow an expert witness to give an opinion that a particular condition is due to a specified cause. Certainly the rule is liberal enough to allow him to say that it might be. The fact that the witness had never had experience with this method of treatment did not disqualify him.

Medical Officer Wrongfully Passing Applicant for Enlistment

(Ex parte Blackington (U. S.), 245 Fed. R. 801)

The United States District Court in Massachusetts holds that the fact that a medical examiner may have wrongfully passed an applicant for enlistment does not give the latter any legal right to be discharged from the Army on a writ of habeas corpus. The court says that the petitioner in this case, a member of the bar, claimed that when he was about 3 years old his head was kicked or stepped on by a horse, the calk in the shoe puncturing both the outer and the inner plates of the skull. Trephining was done, and a piece of the skull about half an inch in diameter was removed, but no plate was inserted. The wound was in the front part of the left temple, near the outer corner of the eye, and is now indicated by an obvious indentation. The petitioner's height is 5 feet 3 inches. In June, 1917, he enlisted as a private in a battery of heavy field artillery that was a part of the Maine National Guard, which he expected would shortly be called into the federal service. The medical officer who examined and accepted him for service had conceived a violent animosity toward him because about a year previously he had had occasion in the course of his business to collect a debt from the officer's sister, and the officer said he would get even with him for annoying his sister; that he understood that Blackington was going to enlist in the heavy artillery, and, if he did, he would pass him if he could not see beyond the end of his nose, and would see to it that he was passed by the federal medical examiner, etc. Within a day or two after the enlistment became complete, the petitioner consulted two other physicians on the question of whether he could safely perform military duty, especially near cannon in action, and was informed that he could not, and from that time he consistently endeavored to obtain his discharge from the service. After the regiment in which he enlisted was drafted into the United States Army he was examined by the federal medical officers, and was accepted by them. Nothing whatever appeared which cast any suspicion on the fairness of their examination, unless the remark above quoted be so regarded. No direct evidence was offered by the petitioner that his physical condition was such that military service would cause more injury or hardship to him than to the average man. The court is of the opinion that, on his own evidence, the petitioner was not entitled to be discharged; and dismisses his petition.

The recruiting officer, or the medical examiner, acts solely for the state or for the United States. The purpose of the examination is not to give to the applicant assurance that he is physically fit for military service, but only to prevent undesirable men from getting into the Army, where their presence would cause difficulty and expense. So, too, the Army regulations governing recruiting are established for the good of the service, and may be waived by the applicant, not of the prescribed height, whose offer of service was nevertheless accepted. As to the effectiveness and bodily soundness, the Army has the right to fix its own standards—if not absolutely, at least within much wider limits than were approached in this case. If the medical examiner, in violation of his duty as an officer, accepted an unfit man, that was a matter for which he might be called to account by his military superiors; but it was nothing that a recruit passed by him could take advantage of, whether such action was inspired by personal hostility, or was the result of mere negligence.

Social Medicine, Medical Economics and Miscellany

OBSTETRIC SUPERSTITIONS*

PAUL TITUS, M.D.
Obstetrician, Western Pennsylvania Hospital
Pittsburgh

Every once in so often, one can take up a medical journal and find an article with a heading something like this: "Obstetric Superstitions Prevailing among the Borneo Head-Hunters" by Dr. So-and-so, who has just returned from being a medical missionary in the Malay Archipelago. Or it may be that Dr. Somebody-else who has been doing Army work in our insular possessions has written very cleverly on "The Childlike Beliefs of the Filipino Regarding Obstetrics, and Some Curious Ideas of the Native Midwives." We read these interesting little monographs in a superior sort of way, smile with a sort of "holier than thou" smile, and patronizingly remark, "Now, isn't it quaint that these poor benighted heathen should believe such ridiculous things!"

It has occurred to me, however, that perhaps we do not have so much right after all to smile at these unenlightened savages, for I have been obliged to assert repeatedly to pregnant patients that raising the arms above the head will not twist the cord around the baby's neck. I have had to tell others that decayed teeth should be taken care of during pregnancy, in spite of the fact that they had been earnestly assured by any number of their friends that they must not have any dental work done while in the family way. And an irate newly made grandmother nearly discharged me on one occasion, when I insisted that she stop picking up the new baby whenever it cried, because she had known for a very long time that "a boy baby must never be allowed to cry for fear of rupture."

There are so many obstetric superstitions and ideas extant, and belief in them is so widespread and common, that I have endeavored to collect them as I have heard them, and to group them according to a similarity of belief or origin. It was not difficult to compile a list of ninety-eight superstitious ideas, and there are, without doubt, many more which have been completely missed. It is interesting to note how well founded on facts a few of them are, while others are a combination of medicine and folk-lore as taught by the ancients, and both the good and the foolish ones are amusing.

If a consideration of the subject of menstruation is permissible under the heading of obstetrics, the first superstition to present is: "A menstruating woman is unclean; if she touches a mare which is with foal, the mare will miscarry; she must not handle milk or it will turn sour; she will be unsuccessful in making jelly, for if she attempts it, the syrup will not solidify." To this superstition may be added the beliefs that if a woman has no children she is likely to have an early menopause, and if a young woman misses a period she will develop consumption; also, if a woman becomes pregnant again after having had a child and no periods have occurred between the two pregnancies, the second child will be sterile.

Coming to the subject of pregnancy itself, we find a multitude of ideas relating to the various ailments of pregnancy: "After the skin grows on the baby, the nausea will stop." "Popcorn is good for nausea of pregnancy." "The husband sometimes has the nausea of pregnancy for the mother." As an additional bit of evidence that the husband counts for something in obstetrics, I would cite the fact that the husband's getting toothache is considered a sign of pregnancy, and one may count from the date of the toothache in estimating the expected time of confinement. "Heartburn makes hair on the baby," or, to express it a little more clearly, "heartburn means that the baby is going to have a great deal of hair," and to cure it, it is recommended that for heartburn one must eat raw potatoes. "Getting the feet wet will cause polyhydramnios," the relation here being quite obvious. "The head of the baby sinks into the pelvis in the dark of the moon," but "if the patient has gone overtime this can be remedied by dropping new pennies on the floor." As a means of determining about when to call the doctor, you may have your choice between "the occurrence of wild pains indicates that the baby will be born two weeks later to the day," and "if the baby does not come on the exact date calculating from the last period, it will be precisely two weeks late." A pseudocyesis is called a "wind-baby," usually with good reason.

---

* Read before the Pittsburgh Academy of Medicine, Feb. 5, 1918.

If a young couple desire to arrange beforehand to have either a boy or a girl, as their fancy dictates, they have only to follow these directions: "In order to beget a boy, the father must go to bed with his boots on;" or, "if a boy is desired, coitus should take place before the period, but if a girl is wanted it should occur after the period;" or, "have coitus on the left side to beget a girl, on the right side to beget a boy;" or, "the mother should eat freely of peanuts during her pregnancy in order to have a boy, whereas if she wishes a girl she should eat a great deal of sweet stuffs of all kinds." It is said that "the right ovary produces a boy, the left a girl." But should the prospective parents have any doubt, they will be able to tell absolutely which to expect by the fact that "if a patient has a high color, she may expect a girl," whereas "if the unborn baby is a girl, the patient will be more nauseated than if it is a boy." "If the fetal heart sounds are above 140, one may expect a girl, if below, a boy," because of the fact that a woman's pulse is faster than a man's, this having been applied to male and female fetuses. "If the baby is carried high in front it is a boy, but it is a girl if carried low and the patient is broad in the back"; and anyway, "more boys than girls are born in war times."

The question of maternal impressions and markings of the unborn baby is hopeless. The farther one goes, the deeper into the subject one gets. Suffice it to say that all sorts of things, from black cats crossing one's path to eating strawberries and watching workmen either fall from scaffoldings or stagger home drunk, will mark the baby in various ways. This is all so definite, in fact, that one never need be at a loss to account for any peculiar markings or malformation the newly born baby may show. If the mother, preferably with the help of one or both grandmothers, will merely think back over the nine months of pregnancy, the explanation is sure to be found. There are one or two very important things in the way of maternal impressions that should be avoided during pregnancy. "If the patient raises her arms above her head for any reason, the cord will be twisted around the baby's neck." "The mother must not touch her face, as a habit, or the baby will be marked on the face." "If the baby sticks out its tongue after its birth it means that the mother intensely desired some article of food during pregnancy. If some of this is put on the baby's tongue, this habit will cease."

It is very nice to be able to give one's patients a favorable prognosis as to the character of their labor, and this may be done if one will remember that "if a woman has a large mouth she will have an easy labor, but if the mouth is small, a difficult labor." "More babies are born at night than in the day time," a circumstance probably due to the fact that the moon, which ordinarily shines at night, is responsible in some mysterious way, for it is well known that "the change of the moon starts pregnant women into labor."

The old superstition that the first baby often comes early has more than once proved a good alibi. In connection with this, the fact that "a seven months' baby has a better chance of surviving than an eight months' premature infant" is true, either because it sometimes takes a couple of months to find out that one is pregnant, with a subsequent rush to the marriage license bureau, or else this idea is a survival of the time when seven and multiples thereof were considered lucky numbers.

It is said that oil rubbed on the abdomen makes labor easier, and a superstition extant among the negroes to the effect that "intercourse at the beginning of labor will make a light labor" has caused at least one fatal infection that I know of. "Girls make more trouble during labor than boys," and "the breath must not be drawn in during labor, as that draws the baby back," and "one should blow into a bottle to expel the afterbirth if retained," are superstitions that speak for themselves. "The patient must keep her mouth shut after delivery to prevent the womb from dilating," but if it does dilate and hemorrhage results, "one should put an ax under the bed, edge up, in order to cut the hemorrhage," or "give the patient a piece of the afterbirth to eat, in order to stop bleeding." "For convulsions, tie pieces of fresh onion over the radial artery." So far as twins are concerned, "it is bad luck for a mother to have boy and girl twins because the mother in all likelihood will not survive."

After the patient has had her baby, it must be remembered that "sheets must have been slept in, in order to take off the chill before the bed is occupied by a puerperal woman," and "an abdominal binder preserves the figure after delivery." It is better to acquiesce in the latter idea, else some woman who has grown stout after the arrival of her offspring may blame her physician for the loss of her figure. "If the mother does not sleep after delivery, put her shoes under the bed with the toes out." If the patient complains of after-pains, you can comfort her by pronouncing the dictum, "the more babies the more after-pains" and, so far as that is concerned, "for every child a tooth." If you must tell the patient that her after-pains are due to the fact that the uterine tone is lost more and more with each baby and that greater effort on the part of the uterus is required each time in order to expel collected blood clots, she will probably tell you that you are altogether too scientific. "Eating fish during the puerperium will cause flooding," but even so, "the patient must bleed forty days after delivery for purification."

"A patient must not have her hair combed while in bed after her baby has come, because this causes brain trouble," and this covers the whole subject of puerperal psychosis much more briefly than the average psychiatrist can do it. The ninth and tenth days of puerperium are troublesome, because "the uterus drops back on the ninth day," and "the bones go back with a click on the ninth day." Even though it is considered by those who believe in this superstition that it may be perfectly proper to get up on the fourth or fifth day, one absolutely must be in bed on the ninth day. "Milk-leg occurs on the tenth day," and "a patient must on no account get up for the first time on Sunday."

In connection with the care of the breasts in nursing the baby, there is a series of ideas, chief of which are: "There are nine days of sore nipples." Breast engorgement is called "the weed." "If one catches cold and it settles in the breasts, one will get a 'bealing' or a 'gathering' in the breasts." "The mother's intestinal gas is transmitted to the baby through the milk." "Tomatoes are acid and should not be eaten by a nursing mother." "Acid food taken by the mother sours the milk." "The mother must never drink water while nursing the baby because it will strangle the child." "She should not take hold of cold scissors or any other sharp, cold instrument because the milk will be chilled." "Ice cream freezes the milk."

Where the grandmothers and midwives shine and folklore runs riot is in the care of the young baby. In the first place, "a boy baby's cord should be cut long so that it will be virile when it grows up," and for the same reason, "one should turn the stump of a boy baby's cord upward." Then burnt gauze is applied to the cord, which really is not bad as a sterile dressing. "Give the baby a teaspoonful of water immediately after birth and it will never have colic," and do not worry if the baby gets thin, because "a baby loses weight as long as the cord remains attached." "If a new-born baby has a surface likely to be exposed to friction, moisten with the mother's saliva and it will not chafe." This superstition is offered for what it is worth to the pediatricians, as well as the one that a boy baby crying will rupture himself. Every one knows that "light hurts a baby's eyes," although it does seem reasonable to suppose that babies would close their eyelids if it did. Considering eyes, we should remember that some babies get sore and discharging eyes; so to prevent this, "wash the baby's eyes with urine." If that fails, "breast-milk is put in sore eyes" and will positively cure them.

Both boy and girl babies occasionally have breasts engorged with secretion, and because there is no especial reason for it, it is supposed to have been caused by a witch and therefore is rightly called "witch's milk."

"If a female child's tongue is tied, it need not be touched," for obvious reasons. "If the baby wrinkles its forehead and rolls its eyes upward, it is a sign of weak-mindedness." "Babies must be picked up, else they will become liver-grown." "If a child has convulsions, keep its hands open because if the hands become firmly clenched the child will not relax and will die," or "salt the palms of the hands of a child with convulsions." "Tie up a baby's hands because it gives him a sense of security," and watch carefully so that "if a baby yawns you may make the sign of the cross over its mouth in order to prevent the devil from jumping down its throat." Also, one must always say "gesundheit" or "God bless it" when the baby sneezes, "because at this time its soul leaves its body for a moment."

The dicta that "a baby should be taken upstairs with a gold piece in its hand before being taken down, so that it will rise in the world," and that "a child's finger and toe nails should be bitten off instead of clipped for the first year, so that it will not become a thief," should be carefully observed because of their profound influence on the child's later life. I commend to the pediatricians as being much simpler than fussy formulas in cases of malnutrition the fact that if you "measure a sickly child and repeat a doggerel, each part measured grows. Tie knots in the string used for making the measurements and throw it away."

"After delivery, one must go downstairs backward for the first time," and "having a baby is good for a patient with epilepsy," while "the use of the baby's urine on the mother's face and hands will help preserve her complexion."

It is considered very lucky to be born with a caul, and "any one possessing a caul will never drown at sea." It will be remembered that Dickens' David Copperfield "was born with a caul, which was advertised for sale in the newspapers, at the low price of fifteen guineas. Whether sea-going people were short of money about that time," David says, "or short of faith and preferred cork-jackets, I don't know; all I know is that there was but one solitary bidding and that was from an attorney . . . who offered two pounds in cash and the balance in sherry, but declined to be guaranteed from drowning on any higher bargain. Consequently the advertisement was withdrawn at a dead loss, . . . and ten years afterward the caul was put up in a raffle down in our part of the country, to fifty members at half-a-crown a head, the winner to spend five shillings. I was present myself, and I remember to have felt quite uncomfortable and confused at a part of myself being disposed of in that way. The caul was won, I recollect, by an old lady with a hand-basket . . . It is a fact which will be long remembered as remarkable down there, that she was never drowned but died triumphantly in bed, at ninety-two. I have understood that it was, to the last, her proudest boast that she never had been on the water in her life except upon a bridge; and that over her tea . . . she, to the last, expressed her indignation at the impiety of mariners and others, who had the presumption to go 'meandering' about the world."

It was David Copperfield, too, who was born "on a Friday at twelve o'clock at night." To paraphrase his own words, in consideration of the day and hour of his birth, it was decided by his nurse and some sage women of the neighborhood who had taken a lively interest in him several months before there was any possibility of their becoming acquainted with him, that he was destined to be unlucky in life and privileged to see ghosts and spirits, both these gifts attaching to all unlucky infants of either gender, born toward the small hours on a Friday night.

The natural result of all this knowledge, with the evil results that must follow any lack of such knowledge, is that obstetrics has become a specialty! I defy any one to attempt to know all these vital facts that have been outlined unless he gives the subject his undivided attention. Even then he may not do at all, because "it is most unlucky to have a left-handed doctor in attendance on you during confinement."

It would be a waste of time to gather together these ideas merely for the amusement they might furnish. The lesson to be gained from this collection is that women are unduly impressionable, at least about obstetric affairs. When it is considered that obstetrics forms one of the main topics of conversation at Red Cross meetings and bridge parties, it will be understood how such a multitude of fanciful ideas have sprung up and can be kept in existence. Many of these things are firmly believed; and while only a few of them are likely to cause actual physical harm to a pregnant woman, the mental impression on her is most pernicious. Recently, a patient of mine neglected her teeth to such an extent that she developed a pyorrhea which was followed by pyelonephritis. Nothing that I could say could convince her that it was safe to have dental work done during her pregnancy.

A few women seem to take peculiar delight in telling all the horrible obstetric tales they can think of to their pregnant friends, and the doctor is constantly called on to combat the fears that thereby arise.

Mental disturbances of pregnancy and the puerperium are dreaded complications. The less the pregnant woman thinks about herself, the better, so long as her condition is normal and her progress is being watched by a competent physician. Pregnancy is a physiologic process, not to be shrouded in mystery and surrounded by superstitious ideas. It is my opinion that if the physician is more or less familiar with some of the superstitions I have mentioned, he is better able to allay the fears and explain away the doubts that these old-wives' tales produce.

Report of Harvard Cancer Commission

The work of the Collis P. Huntington Memorial Hospital for Cancer Research and of the laboratories of the Cancer Commission of Harvard University for the year ending June 30, 1917, as summarized by Dr. J. Collins Warren, chairman of the commission, states that in a period of a little over five years the commission has been able to build, equip and conduct a hospital of twenty-five beds and to establish a plant, including its dispensary and laboratories, costing about $600,000, and involving an expenditure annually of about $50,000. The research in cancer was at first conducted by the pathologist and the parasitologist, but thus far cancer has not been placed on a microbic basis. The methods of treatment tested include the Hodenpyl serum and the colloidal solutions. The more recent researches and tests have been with reference to the employment of radium and other forms of the application of light rays, and the physicist has been called in, and under the direction of Dr. William Duane, a department of biophysics has been established by the corporation of the university. In connection with the experts of a plant manufacturing electrical apparatus, Dr. Duane has been earnestly engaged in the development of a high frequency and high tension generating plant to be used in connection with the Coolidge tubes for the production of deep penetrating rays which will have the effect of the gamma rays of radium. In this connection, Dr. W. T. Bovie has conducted productive research on the action of the rays of light on the living cell in a state of active division, and has secured new apparatus for carrying on the work. These researches have an important bearing on the problem of cancer growth. The possible chemical solution of the cancer problem has been studied by Dr. Henry Lyman, and Dr. Redfield has made important observations of the effects of radium rays on embryonic tissues. An additional building to be occupied by the laboratories is demanded and will be provided on account of the constant expansion of the work. For the physicians and hospitals of the state, free diagnostic service with relation to cancer has been provided, in connection with which microscopic examinations will be made by competent authorities. Instruction in nurses' laboratory technic has been given during the year by Miss Gibson, who has prepared a textbook on the subject. The chairman says that the work of the past year has shown that slow but steady progress is being made toward the solution of the proper method of treatment of cancer. In the more superficial forms many cures are effected by radium, of which the hospital now has 1 gram. In some internal forms of malignant disease, the results of radiotherapy are encouraging, even though alleviation of suffering for a period is the only result in many cases. Too much stress, the chairman says, cannot be laid on the fact that, in its early stages, cancer is a curable disease.

AMERICAN ASSOCIATION OF IMMUNOLOGISTS

Meeting held at Philadelphia, March 29 and 30, 1918

(Concluded from page 1330)

A Skin Reaction to Pneumotoxin

Mr. Charles Weiss, Philadelphia: This study has been instituted with the idea of using the endocellular toxin of the pneumococcus (hematoxin) rather than the bacterial emulsion. The protein living free pneumococci were dissolved in sodium cholate. A specific reaction was obtainable in guinea-pigs and also in persons *suffering from* lobar pneumonia. The guinea-pigs were sensitized by a sublethal dose of pneumotoxin. The skin test would appear to be a true test for the presence of pneumotoxin in the body of the animal. By various chemical tests it is found that the pneumotoxin is a true protein, and in human lobar pneumonia cases there was a positive reaction demonstrable throughout the toxemia. In children the reaction was most *characteristic.* In other cases tested, in such diseases as tuberculosis and appendicitis, a negative test was given to the pneumotoxin.

The Influence of Arsphenamin (Arsenobenzol) and Mercury on Antibody Production

Drs. John A. Kolmer and I. Toyama, Philadelphia: The possibility of certain drugs acting as antigens has been the theme of several studies by different workers. The antigenic action of drugs may account for acquired drug tolerance and also aid in resistance to infection by stimulating antibody production against microparasites, apart from direct action of the drug on the parasite. The latter phase of the subject is the one particularly dealt with here. Considerable evidence points to the conclusion that many drugs exert a stimulating action on antibody production by the tissues. Such drugs as arsenous anhydrid, phosphoric acid and mercuric chlorid, administered by mouth, are found to act in this manner. Arsphenamin appears to stimulate agglutinin production, according to some workers. The present experiments were conducted on rabbits, to determine if small daily doses of arsphenamin and mercuric chlorid tended to increase antibody response to alien erythrocytes or to typhoid bacilli. After a series of experiments, five in all, on a large number of rabbits and control animals, it was found that no increase of antibody production was shown, after injections of arsphenamin or mercuric chlorid. On the contrary, it would seem that there was a lowering of antibody production, probably due to lessening of resistance by toxic effects. Further experiments, however, are in progress, on the action of these drugs in experimental trypanosome infections. It is felt that such work should be done on human serums, as work on the serums of lower animals *may not* be a true index in human cases.

The Bacteriologic Study of Postoperative Pneumonia

Miss Miriam Olmstead, New York: I studied 130 cases of postoperative pneumonia, and recorded the recovery of a pathogenic organism in thirty-one cases, a percentage of 23.8. In two cases there was the Type I pneumococcus in the blood stream, one of these pneumococci in preoperative and postoperative sputum. In one there was the Type II pneumococcus in the sputum, before and after operation, and the urine was precipitated by pneumococcus Type II serum. In two cases with an atypical Type II organism in preoperative and postoperative sputum, the etiology was established, in one by a positive agglutination test of the patient's serum, and in the other by a urine precipitin reaction with Type II serum. Type III was established as the inciting factor in five cases; in one there was a positive blood culture; from one the organism was obtained by lung cultures at necropsy; the blood of two agglutinated the Type III, recovered from the postoperative sputum. The urine of these two, and one other, who had Type III in the preoperative sputum specimen, gave a precipitin reaction with Type III serum. In eighteen cases, Type IV was the factor, once being recovered from the blood, and seventeen cases gave a positive agglutination reaction with strains from the sputum. In one of these cases the urine precipitated with Type IV serum. In one case a hemolytic streptococcus was found in the blood stream, and in another a hemolytic streptococcus in the sputum gave a positive thread reaction with the patient's serum. A mucoid streptococcus was found in the sputum and chest fluid in one case. Some of these organisms were undoubtedly the inciting factors of other postoperative pneumonia cases, but no direct evidence could be obtained as to this view. The most common factor was Type I.

DISCUSSION

Dr. A. F. Hess, New York: Did pneumonia develop among cases in which the pneumococcus was absent, and if so, how many? In what percentage of cases was there discrepancy in the type of pneumococcus in the preoperative and the postoperative sputum when pneumonia developed?

Dr. J. A. Kolmer, Philadelphia: How many patients with pneumococci in the blood stream died? How many showing precipitin reaction died? My impression is that persons showing the precipitin reaction have rather a bad prognosis.

Miss Olmstead, New York: Those persons who gave a urine precipitin test did not seem to have a bad prognosis. No patient died. Three patients had Type III in the sputum and gave precipitin test reactions. No patient died. In reply to Dr. Hess, in three cases there were postoperative findings of pneumococci in the sputum, when none had been demonstrable before operation. The majority of patients had pneumococci before and after operation.

Active Immunization Against Pneumonia

Dr. R. Kohn, Boston: Lister gave large doses of heated dead pneumococci of virulent types, at six or seven day intervals. In active immunization against all types, agglutinins and opsonins could be demonstrated eight months afterward. Reports constantly show the desirability of protection against pneumonia. It is believed, however, that immunity against pneumonia was of short duration and that the immune serum deteriorates. Tests were made to discover the protective power of blood serum against infection in white mice, injected intraperitoneally. It was found that normal human serum would protect mice against the minimal lethal dose. Some serum protected against a particular strain. It was found that most persons could be immunized against Types I and II, possibly III, and that after nine months the immunity had not diminished. It may last one year, possibly more. There is no evidence that it is absolutely protective. Adverse conditions may result in a lowering of the danger point.

Dr. Augustus B. Wadsworth, Albany, N. Y.: I feel a great deal of interest in this work. I have found that different individuals, exposed to different pneumococcus infections, manifest different degrees of immunity from time to time.

Dr. William H. Park, New York: I can cite an interesting case. In the South of France there was a great deal of pneumonia at one camp. The men were vaccinated with cultures from the camp, and in eighteen days the pneumonia disappeared. Another camp used the same vaccine and the results were negative. Using the culture from a camp 50 miles distant did not seem to correspond to the type of infection. It was striking that the cessation of the epidemic in the first camp followed the use of the vaccine.

The Production of Pneumococcus Serum, and the Corresponding Curves Obtained by Protection and Agglutination Tests

Dr. G. B. White, New York: The unusual demand for antipneumococcus serum has urged us to put forth every effort to increase the yield from our serum horses. The problem thus has arisen as to how best to spare the horses. The conservation of the animals is an important thing. The heavy draft horses seemed to stand the bleedings better; the lighter types do not last long. A vicious horse with "a great deal of game" is the best type of producer. Type I strain, in virulent culture, is necessary to produce Type I antiserum. If live organisms are used, the preparation is made fresh each time and injected intravenously. Three daily injections of dead cocci are made, then three of living; after a week this is repeated, and six days after the second weekly injection the horse is bled. A standard method had been evolved by which 1 c.c. of serum protects against 0.1 c.c. of Type I pneumococcus. The serum is tested against the maximal amount of culture it will neutralize; also the smallest amount of serum that has protective power is estimated.

DISCUSSION

Dr. A. P. Hitchens, Glenolden, Pa.: What is the plan of bleeding as regards the time of injections? What is the interval between the injections?

Dr. J. F. Anderson, Washington, D. C.: We have been using a method of six daily injections, in three courses, with seven day intervals. The horse can be bled in thirty-two days. A standard was made to protect against 0.1 c.c., 0.2 c.c. and 0.3 c.c. culture.

Dr. G. W. McCoy, Washington, D. C.: One point is the unreliability of the agglutination power as compared to the protection value. We have had strains sent back marked "N. G." because they did not agglutinate Type I pneumococci, but still there was a high protection power. All commercial serum, before being sent out, is tested by the Hygienic Laboratory.

Dr. A. B. Wadsworth, Albany, N. Y.: Did the high protective serum have any agglutination power at all?

Dr. McCoy: No; it had no agglutination power at all.

Dr. Wadsworth: Was it controlled?

Dr. McCoy: Yes.

Dr. White: The horses were bled six days after the last injection. Two courses of injections preceded bleeding. We lost four horses from pneumococcus infection. The first two were protective against 0.1 c.c. culture. Both animals had lobar pneumonia of Type I.

Preliminary Tests to Blood Transfusion

Dr. Arthur F. Coca, New York: There is little to add to this practically closed subject, but certain facts should be kept in mind in regard to blood constituents, where transfusion is required. Individuals fall into four groups in regard to the red corpuscle qualities. Two different agglutinable substances are present, *a* and *b*, and the plasma of human beings contains iso-agglutinating substances A and B. It may be stated that *a* is never present with A. All possible combinations of the substances, however, occur in different individuals; as many as 4,000 have been demonstrated. The four groups are: I, with iso-agglutinable substances A and B in the plasma; II, with BB in the plasma; III, with A; IV, substances lacking. Most individuals are of Types I and II. Transfusion is most favorable when donor and recipient belong to the same group. Most unfavorable results arise when the recipient's plasma contains agglutinins for the donor's corpuscles. As regards technic: Venous blood is obtained, citrated, and the serum of the patient is mixed with washed corpuscles of the donor, and vice versa. If agglutination be present, it does as much harm as hemolysis; hemolysis never occurs without agglutination. One point to bear in mind is that the donor's blood, not being anemic, is richer than the recipient's blood. One part of the donor's blood to nine of the patient's is sufficient. In this proportion agglutination will take place at once, if at all, and can be readily detected.

DISCUSSION

Dr. John A. Kolmer, Philadelphia: I should like to refer to a technic that has been employed during the past year and is somewhat similar to that demonstrated by Dr. Coca; this is the microscopic method with Lee's technic. Two tubes are used, one containing 1 c.c. of sodium citrate in a dry test tube, and one with blood. We use blood from the patient and from several donors (separately). The clots are broken up in the platinum loop. We use two drops of patient's serum with one drop of corpuscle suspension of each donor; then two drops of serum from donor and one drop of corpuscles from the patient. Observations are made at the end of fifteen minutes, when agglutination, if any, is marked.

Dr. A. F. Coca, New York: The choice of methods lies with the individual and what apparatus he has at hand. As regards transfusion without preliminary tests, it is known that death has occurred from this procedure, and the surgeon may meet serious trouble.

The Isolation, Purification and Concentration of Immune Hemolysin

Dr. M. Kosakay, Philadelphia: These studies were made in the Institute of Forensic Medicine, Tokio Imperial University. The concentration of antibodies for the purposes of serum therapy, and the elimination of serum proteins in order to avoid serum sickness, were the objects of the research. First, elimination of serum proteins was attempted; second, extraction of immune bodies by antigens and the use of inorganic substances, such as charcoal. Separation of antibodies from the antigenic substance was found possible. Antibodies were found to be coagulable by high temperatures. The serum elements were removed by washing in sodium chlorid, and the antibody in the final preparation could be measured. The corpuscles were treated with hypertonic sugar solution, which does not produce hemolysis; the corpuscles thus remained intact with the hemolysins attached. Some antibodies were discharged into the sugar solution at ordinary temperature, but more were obtained by raising the temperature, to as high as 60 C., without producing hemolysis. Five sixths of the antibodies were thus discharged, and the concentration was found to be of some value. The supernatant fluid was found to contain hemoglobin, and the attempt was made to get rid of this protein by shaking the sugar solution with ether. This produced three layers: first ether; second, gelatinous mass; third, clear layer of sugar and hemolysins. The latter was dialysed and the sugar removed. When the sugar-free, salt-free solution was evaporated, the hemolysin was left and was five-sixth full strength. It was free from protein reactions.

DISCUSSION

Dr. William H. Park, New York: Was Dr. Kosakay able to separate the antibodies from the bacteria, as well as from the red cells?

Dr. John A. Kolmer, Philadelphia: Is it possible to secure the hemolysin alone, from the immune serum by this method? Is the final solution free from hemiagglutination?

Dr. M. Kosakay, Philadelphia: It is a good idea to make the hemolysin free from bacteria. It has not been tried. I have not been able to separate the hemiagglutination from the hemolysin.

A Method of Preparing Bacterial Antigens

Lieut. J. C. Small, U. S. Army: This work is ba
the fact that fatlike substances occurring in the ba

greatly interfere in the aqueous solution of bacteria. No entirely satisfactory method for extraction of bacteria has been accomplished. All methods are directed toward disintegration of the bacterial cell, with the idea of extracting the fragments; but this is better accomplished if the fat and lipoid constituents of the cell be removed. In the present method a chloroform-ether mixture was used to extract the fatlike substances from dried bacteria. The residue was suspended in physiologic sodium chlorid solution. The chloroform ether extraction was found to break up the integrity of the bacterial cell, so as to facilitate its more ready extraction of the fragments by aqueous solution.

DISCUSSION

Dr. J. A. Kolmer, Philadelphia: With regard to heating immune serums at 62 C., I think there is deterioration of specific antibodies present in the serum. This is, however, difficult to measure, as it is hard to differentiate specific from nonspecific factors.

Miss M. A. Wilson, New York: In our experience there is no deterioration. We do not add preservative to the antigen.

Dr. H. von Wedel, New York: In using tubercle bacilli antigen, it was heated five or six times at intervals, and the value remained, as far as I could tell, exactly the same.

Dr. G. H. A. Clowes, Buffalo: If the alkaloids were entirely removed, the temperature could be raised considerably without causing any effect.

Lieut. J. C. Small: I noticed the nonspecific factors in a large series of animals which we were running for typhoid vaccines. Immunization is being carried on and complement fixations and a very large percentage of animals show nonspecificity. Serums with the exception of paratyphosus A, do not show anticomplementary effect.

Experiments on the Passive Transfer of Antibodies to the Cerebrospinal Fluid

Drs. John A. Kolmer and S. Sekiguchi, Philadelphia: The removal of blood from normal dogs, followed by intravenous injection of human syphilitic serum (from 30 to 50 c.c. per kilogram of body weight) caused small amounts of syphilis reagin in the cerebrospinal fluid. This reagin was found in the fluid as early as three hours after the transfusion of syphilitic serum. The amount of reagin found was small. After irritation of the meninges by sterile horse serum, more reagin was found in the cerebrospinal fluid. All traces of reagin disappeared from the cerebrospinal fluid of the dogs within forty-eight hours. Dog typhoid immune serum, injected into a normal dog, intravenously, caused traces of agglutinin to appear in the cerebrospinal fluid within three hours; it disappeared within forty-eight hours. It was thus shown that the passage of antibody from the blood to the cerebrospinal fluid is possible, when the antibody exists in the blood in a high state of concentration. In human syphilis the reagin may pass from the blood, but its presence in the spinal fluid generally indicates the presence and activity of *Spirochaeta pallida* in the organs of the nervous system.

DISCUSSION

Dr. A. P. Hitchens, Philadelphia: The question whether the antibodies can find their way from the blood to the spinal fluid is important, especially in cerebrospinal fever. In cases of severe meningitis in the Army camps, we gave intravenous doses as well as intraspinal, of the antimeningitis serum. Results of this line of treatment are encouraging. Dr. Kolmer's work seems to show that this line of treatment is of value.

Dr. J. Bronfenbrenner, Boston: It is a question as to whether bodies can pass from the blood into the spinal canal. I doubt whether this is possible when the pressure is higher in the spinal canal than in the blood. English workers have concluded that there is a toxin produced by the meningococcus and that this toxin is forced from the spinal canal into the blood stream. If the latter contains antitoxin it would get into the serum, and the improvement would be due to that.

Dr. A. P. Hitchens, Glenolden, Pa.: About every eight hours during the severe part of the disease, we remove the spinal fluid, and with the rapid filling up of the canal again some effect is produced.

Dr. J. A. Kolmer, Philadelphia: This paper simply dealt with the passage of antibody from the blood to the spinal fluid under normal conditions. I cannot agree with Dr. Bronfenbrenner's remarks on the spinal fluid. This is a secretion of the choroid plexus, at least during health. Even when the tension is high, production continues and increases the hydrocephalus. Evidence would prove that the fluid is produced continuously even after rise of pressure.

1. **Spina Bifida Occulta.**—Brickner believes that the following are legitimate indications for operation in cases of spina bifida occulta: 1. In infants and children, spina bifida occulta with congenital lipoma or hypertrichosis, even though without any symptoms—to reduce the spinal hernia into the canal or to meet any other indication that is found, in the hope of obviating the development of symptoms during adolescence. 2. In adults, spina bifida occulta with sufficiently serious and especially with progressive symptoms, whether or not the spina bifida occulta is marked by external signs (lipoma, hypertrichosis). Progressive gangrene of the lower extremities and incontinence of the sphincters are indications sufficient to justify taking this risk. Brickner has found records of twelve operations. He adds five to these all of the seventeen without mortality, and some with decided benefit. In all five operations for spina bifida occulta within Brickner's personal experience there was no untoward result, and the wounds in all cases healed per primam and without any spinal infection.

2. **Diataxia Cerebralis Infantilis.**—The cases cited by Hunt represent an ataxic type of cerebral diplegia which stands in striking contrast to the spastic type of Little and the flaccid or atonic type of Förster. In all of the cases there was a history of severe injury at birth followed by retarded and defective development of the power of motor coordination. There was no paralysis, and if such existed after birth it was of a transient nature and the gross motor power was eventually completely restored. There were no evidences of spasticity. The active and passive movements as well as the reflexes revealed none of the characteristic signs of pyramidal tract involvement. The tonus of the muscles was slightly reduced and the tendon reflexes showed a corresponding reaction, and were moderately diminished and difficult to elicit. There was no undue flexibility of the extremities as occurs in the severer forms of hypotonia. The essential symptom was a generalized ataxic disturbance affecting the gait, station, articulation and the use of the individual members. This was present in all positions, including the recumbent posture, and Hunt emphasizes the persistence of an ataxic disturbance of the arms and legs in the recumbent posture

when no effort was required to maintain the equilibrium. The ataxic disturbance was also increased by closure of the eyes, by mental excitement and by any effort to carry out precise and definite movements.

The disturbance of coordination was bilateral and fairly symmetrical. It affected the finer movements of the hands and fingers as well as movements of the larger joints, and seemed to be equally distributed in this respect. There was, at times, a slight tendency to motor unrest, somewhat suggestive of a choreic disturbance, which Hunt regards as a manifestation of ataxia and the effort to maintain posture. The disorder of motility was clearly ataxic, and was characterized by an inability to carry out precise and definite coordinate movements. It was not in any sense a true chorea or athetosis, the restless ataxiform movements in certain postures merely suggesting the choreiform tendency. Dysarthria was also a well marked symptom, and was regarded as part of the ataxia. There was no nystagmus. The sensibility, both superficial and deep, so far as could be determined by the usual clinical tests, was quite normal. Especially noteworthy was the preservation of the sense of posture and the stereognostic sense. In none of the cases was there a serious mental defect. The retardation was no more than might follow a severe disturbance of speech and incoordination and the restriction of opportunity imposed on the child. In none of the cases was there any tendency to grand mal or petit mal seizures. The convulsions occurring immediately after the birth had manifested no tendency to recur in later life. Some improvement had taken place in all of the patients, and there were no indications of an increasing mental deterioration or progression of other symptoms. In this respect the ataxic form resembles the spastic type of Little with its well recognized tendency to improvement.

4. **Lupus Erythematosus Discoides and Tuberculosis.**—Twelve cases of lupus erythematosus discoides were examined for tuberculosis by Weiss and Singer. All available diagnostic methods were employed and a conclusion was reached in each case by study of the combined results and not from any single diagnostic procedure. Ten out of twelve of these cases showed indubitable evidence of tuberculosis, past or present, and it is believed that the other two are also tuberculous. In only one of their series of cases that were definitely tuberculous was there any likelihood of the presence of a circulating tubercle bacillus toxin. In the authors' opinion no evidence has been presented as yet that shows a relation between lupus erythematosus discoides and tuberculous infection or tuberculous disease. It has been shown that tuberculosis past or present may be demonstrated in practically all cases of lupus erythematosus discoides, and this fact should only be interpreted as further evidence of the ubiquity of tuberculous infection and not as evidence of an etiologic relationship between the two diseases.

5. **Rupture of Aneurysm of Abdominal Aorta.**—Marlow and Doubler report two cases of aneurysm of the abdominal aorta apparently of arteriosclerotic origin which ruptured into the duodenum.

6. **Relation of Congenital Syphilis to Mental Deficiency.**—The results of the serologic studies on fifty cases admitted to a psychologic clinic are recorded by Higgins. The material for this clinic is drawn largely from the retarded classes of the Richmond public schools, the juvenile court, and other agencies interested in the social welfare of the city. They were sent for the purpose of obtaining the estimate of their mental development as well as a clue to any factors influencing their mental and moral stamina. In this series 21, or 42 per cent., gave a positive Wassermann reaction. Their ages varied from 7 to 16 years. The series is composed largely of the middle and high-grade imbecile and only exceptionally with the low grade idiot. Quite at variance with other reports is the striking relative absence of congenital syphilis or organic lesions of the nervous system. Approximately one half showed a general glandular enlargement. Defects of vision, tonsils, etc., were found no more frequently than in the nonsyphilitic series. The most interesting and suggestive physical aspect was the malformation and caries of the teeth. Temperamentally the series presented an interesting picture; fourteen of the twenty-one were either incorrigible, disobedient, or displayed fits of temper unlike those usually seen in the normal child. Higgins feels that the listless, low grade idiot is so likely to be of syphilitic origin as the high strung, passionate child with wayward tendencies.

8. **Urobilin and Urobilinogen.**—With a few slight modifications of technic the authors have used the method of Schneider in estimating quantitatively the amounts of urobilinogen and urobilin in the duodenal contents obtained by means of an Einhorn tube. In a group of twenty-two miscellaneous cases, low values were obtained in patients with anemia from hemorrhage, carcinoma, tuberculous peritonitis, syphilis, portal cirrhosis, chronic infectious arthritis, and gallstones. They were low in three of four patients with myelocytic leukemia. The amounts of these pigments were especially low in cases of anemia from hemorrhage. In hemolytic jaundice the values were consistently high even when severe anemia was not present. The values fell appreciably after splenectomy, but not as promptly as in pernicious anemia. In pernicious anemia the amounts of urobilin and urobilinogen in the duodenal contents were above normal in 84 per cent. of the cases. The amount of urobilinogen was constantly increased when the anemia was severe. Patients over the age of 55 showed lower values than younger patients. The values presented no definite relationship to the size of the spleen. Following splenectomy there was a very definite decrease in the amounts of urobilin and urobilinogen; the decrease in urobilinogen was especially noticeable. The amounts of bilirubin in the duodenal contents did not run constantly parallel to the amounts of urobilin and urobilinogen.

9. **Pleural Eosinophilia.**—Bine reports two cases of atypical pulmonary infections, followed by pleural effusions. In the first case the blood showed 1 per cent. eosinophils, the pleural fluid 51 per cent. Four years later, long after the patient's complete recovery, the blood still contained 32 per cent. eosinophils. In the second case the pleural fluid contained 30 to 40 per cent. eosinophils, the blood 16 per cent., then 14.5 per cent., 10 per cent., and 19 per cent., three weeks after the first count.

20. **Bloodless Repair of Cervix Uteri.**—The method employed by Heineberg is as follows: Hemostasis is secured through the use of two angulated tenaculum forceps and a rubber ring such as is sometimes employed to hold together the tops of umbrella ribs. The chief feature of the forceps in addition to the angulation is a pedunculated ball which is attached to the outer aspect of each blade above the angle. The balls serve the purpose of retaining the rubber ring in a position to compress the cervix above the grasp of the for
The forceps also act as lateral retractors of the vagi

40. **Chlorin Antiseptics in Civil Hospital Use.**—The following conclusions have been reached by Hartwell and his associates after four months' intensive study at Bellevue Hospital with the chlorin antiseptics: 1. The establishment of the Carrel-Dakin technic presents no undue difficulty. 2. The results obtained in the military hospitals abroad can be duplicated in general civil hospitals in dealing with traumatic cases. 3. These antiseptics are not as efficient in controlling spontaneous infections, that is, those not directly due to trauma. They are not as valuable in burns as other forms of treatment. 4. Reasonable care prevents skin burns in all circumstances. 5. Dichloramin-T in either chlorinated eucalyptol or chlorinated paraffin oil is not a completely efficient substitute for the sodium hypochlorite solution. These men feel that four months' experience has satisfactorily demonstrated the practicability and the advantages of using the Carrel-Dakin treatment in those civil hospitals where a considerable number of traumatic cases are treated. In those civil hospitals where a traumatic service is not an important part of the hospital work, Hartwell believes it is doubtful whether the inauguration of this treatment will meet with great success, for the reason that the call for its use will not be frequent enough to make it an established routine. Without this, it probably would be no more effectively applied than is any other special form of treatment which is only occasionally demanded in a general hospital service, and if ineffectively applied it cannot be expected that satisfactory results will follow.

41. **Bismuth Paste in War Surgery.**—Beck's experience leads him to advise the use of bismuth paste in war surgery, where the majority of wounds are infected before they reach the base hospital. Carrel employed the method at the French base hospital at Compiegne in 1916 with satisfactory results, with material and instruments Beck sent him at that time. Richter, in charge of one of the Red Cross units which for a time worked in a German base hospital, also used this method of injecting suppurative wounds resulting from shrapnel, gunshot and bayonet, and reported most satisfactory results. Beck urges that in those cases in which early sterilization was not obtainable and the wounds persist in suppurating, the bismuth paste injection or similar formula should be employed, before another radical operation is resorted to. In the residue of cases in which the bismuth paste treatment is not effective, the sutureless skin sliding operation should be employed, since with this method we are able to clear up nearly all of these apparently hopeless cases.

47. **Value of Radium and Roentgen Rays in Cancer.**—On the basis of clinical and experimental investigations the authors conclude that: It is advisable to radiate malignant tumors not only after an operation, but in a certain class of cases also before an operation so as to sterilize and inhibit the proliferation of those cancer cells which may be left behind or transplanted elsewhere in the course of an operation. Such a procedure does not prolong appreciably the time preparatory to an operation and presents no danger to the patient. The fear expressed by some clinicians that the raying may occasionally irritate and increase the rate of growth of the tumor is unfounded. There is no clear experimental evidence of such irritating action of the rays on young proliferating cells. The result is always an inhibition. The clinical evidence of the existence of an irritating action of the rays is also very vague and not convincing. One must keep clearly in mind the fact that any malignant tumor may suddenly increase its rate of growth and consequent malignancy without any relation to the instituted mode of treatment. In a series of twenty cases of carcinoma of the rectum the following observation was made. In the cases in which an attempt at a radical operation was made the condition recurred with greater rapidity and malignancy than in those cases in which there was no operation done and only radium and roentgen-ray treatment given or an exploratory was done followed by radiations. Similar observations are surely made by any surgeon with a large cancer material. In this series of cases the malignant recrudescence of the disease was not caused by the operative interference, but accidentally took place after the operation. The same holds true of the recrudescences which occasionally may take place after radium or roentgen-ray treatment, thus preoperative and postoperative radiations of cancer as a method of inhibiting the proliferating power and the consequent clinical malignancy of the tumor-cells is of undoubted value and presents no danger.

56. **Recurrences After Biliary Operations.**—Judd and Harrington reviewed the histories of patients operated on for recurrence in the past two years at the Mayo Clinic. There were 2,027 operations, of which 219 (10.8 per cent.) were

secondary. A large number (80 per cent.) of the operations were for the removal of the gallbladder, a procedure which has been accepted in the clinic as the operation of choice. One hundred and twenty of the 219 secondary operations were for the removal of gallbladders which had been drained previously. There was only 0.8 per cent. mortality in the series, showing that the risk in the secondary operation is no greater than in the primary operation. In 4 of the 219 cases, a secondary cholecystostomy was done because the general condition of the patient contraindicated any further procedure. Two of these patients died. In 109 of the 219 operations, calculi were found either in the gallbladder, the ducts, or in both. One hundred and fifty-three patients had cholecystitis, in some instances associated with stones. Adhesions were especially noted in 148 cases, and in 41 there was a definite pancreatitis. Either a mucous or a biliary fistula was present in 37 cases. Seventeen of the 209 patients were definitely jaundiced. At the time of the first operation stones were found in 154 of the 219 cases; in the gallbladder in 140, in the ducts in 9, and in the gallbladder and ducts in 5. Stones were found at the second operation in 109 cases; in 59 cases in the gallbladder; in 9 in the gallbladder and ducts; and in 41 in the ducts. In 64 of the 219 cases both the primary and secondary operations were performed in this clinic. In 37 of this series a drainage operation had been performed primarily; 29 for stones and 8 for cholecystitis. Of the 29 patients with stones in the gallbladder at the first operation, 13 had stones in the gallbladder at the second operation, and 4 of these had stones in the ducts also. Of the 8 cases in which drainage was done for cholecystitis, in 2 stones or stony material which was not present at the first operation was found later. In 12 of the 64 cases, the primary operation was cholecystectomy; in 6 of these stones were removed from the common duct at the second operation. The impressions which Judd and Harrington have gained in reviewing this series of 2,027 cases are that: 1. Removal of the gallbladder reduces the risk of later troubles, and ordinarily is to be preferred to cholecystostomy for drainage. 2. It is not necessary to open and probe the common duct at every gallbladder operation. 3. Infection in the liver, gallbladder, or ducts is the most frequent cause of secondary trouble, and many recur many years after the primary operation. 4. The recurrence of stones is more frequent in the gallbladder than in any other part of the biliary tract. The common duct is next in point of frequency. 5. In a definite small percentage of cases stones will be overlooked in the common duct; in other cases the stones reform in the duct.

107 *New Clinical Test for Temperature Sensitivity. E. L. Cornell, New York.—p. 119.

95. **Cerebral Neoplasm Proving to Be Carcinoma.**—McKendree's patient presented the following symptoms: itching of the right side of the tongue; a sensation of coolness in the right side of the face; pain in the temporal region and forehead of the right side; a sensation of being pulled outward in the right side of the lower lip; the right eye was turned in. The onset was gradual and the course has been progressive. The intensity of the headache has been variable, but it has progressed recently to such an extent that it is almost unbearable. He was never nauseated and never vomited; except for diplopia his vision has been unaffected. He has not lost weight. There have been no night sweats. His bowels are constipated. There is no nocturia. His sphincters are unaffected. He has never been dizzy, except when he attempts to use his eyes without his exclusion glass. His appetite is normal, although he does not taste as well as he formerly did. In the nasopharynx was a mass situated at th

vault about the size of half an English walnut, spongy in appearance with many minute blood vessels appearing on the surface. Gentlest application of a cotton applicator through the nose causes a hemorrhage from this mass. This mass nearly fills the midline, and to the left of the line. It covers one pharyngeal end of the Eustachian tube on the right. Diagnosis: Carcinoma of hypophysis. Tissue removed later during an exploration proved to be definitely carcinomatous and of the same type as that removed from the vault of the nasopharynx, which proves its origin.

101. **Combined Dystrophy with Loss of Vesical Control.**—In summing up the abnormal features of this case McKendree emphasizes the Aran-Duchenne type of shoulder pelvic girdle atrophy; the Erb's type of pseudohypertrophic dystrophy, the absent ankle jerks, and the vesical incontinence. All of these occurred in a man who is one of three who are similarly affected (except for the bladder symptoms). This case, though not typical of any one type of dystrophy, apparently represents a combination of three well known types of myopathy.

103. **Multiple Sclerosis with Kymographic Studies of Tremor.**—This is a case of definite ataxia, equilibratory and nonequilibratory. The patient cannot stand steady with the feet together and cannot stand at all with the eyes closed; she has an ataxic gait, a coarse intention tremor of both arms and legs, with a mild tremor of the head. She has a dysphonia; also an absolute inability to write, owing to the wide excursions of the tremor. There is a strong probability of Gordon and Schäfer on the right side, practically certain, and the possibility of a Babinski on that side (doubtful). The upper lateral abdominals are possibly unequal, the left less constant than the right. The patient gives a history of gradual onset over a period of five years, including several spells of falling, due to a sudden giving way of the right leg; no loss of consciousness. She also gives a history of several (probably six) fainting spells, the cause of which is not made clear and, further, several attacks of a "hysterical" nature. Hallock is certain that these symptoms point rather definitely to a diagnosis of multiple sclerosis although the reflexes are nowhere exaggerated and are even diminished in the legs and there is no sign of spasticity; and there is an absence of fundus changes and nystagmus. The tracings of the tremor made are of the multiple sclerosis type.

107. **Clinical Test for Temperature Sensitivity.**—Cornell summarizes the results of her study as follows: More than half of the total number of reactions to simultaneous cold and hot stimulation elicit first cold, then hot. The back and abdomen have a higher percentage than other regions of such responses. The proportion of responses to double stimulation that does not include both responses is small—8 per cent. on the average, with a minimum of 3 per cent. and a maximum of 20 per cent. The reaction time to cold and hot stimuli separately does not show any distinct difference, as measured in this way, except perhaps on the abdomen and back. The length of the first interval, when "cold" is the first response to the double stimulation, is about 1.0 second; the length of the second interval, about 0.4 second, on the average. A second interval of more than 1.0 second is rare. The order in which the response occurs whether "cold-hot" or "hot-cold" is probably dependent in part on the simultaneity of application and in part on physiologic conditions. Individual differences in all of these respects are so considerable that a wide deviation from the average must be admitted as normal.

2. Irritable Heart Treated by Graded Exercises.—Nearly 3,000 patients with diagnosis of "D. A. H." (disordered action of the heart) or "V. D. H." (valvular disease of the heart) have been submitted to graded drills by Lewis and his associates. There has been no single accident of consequence. Where several hundred men are drilled each day, a fainting attack on drill is less than a monthly incident. The chief form of attack, and one which may always be regarded as genuine, is that accompanied by a feeble and slow heart action (30-50). It may be preceded by a short interval of giddiness, by a sense of weakness or unsteadiness. Consciousness is lost, and the fall is sudden, but rarely heavy. Pallor and sweating are present. Involuntary movements are slight, and usually confined to the face and arms; a general rigidity may be developed; the tongue is not bitten, neither is the urine passed. Nausea or vomiting may be present. The attack lasts from a few seconds to a few minutes, and is followed by lassitude and headache. A history of earlier attacks is common; these are associated usually with emotion (sight of blood, etc.), long standing at attention or the cessation of sudden effort; they do not occur in recumbency. Recovery is always complete, and an attack should not break the routine of drill for more than forty-eight hours.

Lewis says that attacks which are inconsistent with this picture are to be viewed with suspicion unless they may be ascribed to epilepsy. A complaint of fatigue or exhaustion is rarely unaccompanied by other complaints, and may be disregarded unless often repeated and accompanied by signs, such as pallor, or by uncontrollable tremor of lips or limbs, or by signs of breathlessness, as the grade of exercise is raised. Stiffness of the limbs or trunk muscles, accompanied by tenderness, is experienced by some unpromising cases to an unusual degree as an after-effect of short exercise. Pain in the axillary region, back, or limbs is usually related to a particular action during drill, and as a general rule does not endure.

4. Treatment of Gas Gangrene.—Gray urges the wide recognition and application of a principle which he believes is essential for the successful prevention and eradication of gas gangrene in war wounds met with in France. The causative bacilli of gas gangrene will not develop in tissues which are provided with a vigorous circulation of healthy blood. They thrive best when the circulation is entirely stopped, for example, in a person dead of gas gangrene or in a limb of a living person where the main vessels have been severed. Long application of a tourniquet often allows the infection to obtain a firm hold. Feebleness of circulation in the wounded part, whether from a general cause, such as shock, or from a local cause, such as tension, from effused material or pressure of foreign bodies, favors its development. The injured muscle or group of muscles is deprived, in part or in whole, of its normal blood supply according to whether the missile severs the main nutrient vessels or merely causes isolation of lacerated portions. Pressure in the neighboring parts, whether caused by effused material in the wound, by inflammatory reaction, or by external constriction, interferes still further with the circulation, and forms a most important arc of the ever widening vicious circle of spreading inflammation.

From purely clinical observations, the following principle has been evolved by Gray: Whether one undertakes preventive, preinflammatory operation, or curative operation after the gangrene has developed, success and safety are assured only when the wounded parts are excised until definite bleeding of the cut surface is seen. The bleeding must be definite; it need not be free. In preinflammatory operations the use of a tourniquet during operation may be permissible; it is not advisable unless the patient is exsanguiante. In cases in which gangrene is already well marked it should not be used. Care must be taken that in excising parts at the later stages of the operation the blood supply of tissues left behind at an earlier part of the operation is not interfered with; therefore, as a rule, proximal parts should be excised before distal parts. Gray has usually found it easy to decide, when this principle is kept in view, how much should be excised—whether only part of a muscle, the whole muscle, a group of muscles, or the limb. Surgeons who base their work on this principle have more success, and have to perform fewer secondary operations than those who do not follow it.

6. Treatment of Psoriasis in Army.—Out of 1,100 patients admitted to the hospital for skin disease, Barber says, fifty-six (that is, about 5 per cent.) are being treated for psoriasis. In order to return these cases to duty as quickly as possible he has adopted the following method, which has afforded more rapid and uniform results than any other that he has yet tried. The patient attends for treatment twice daily. Every morning he is given a bath, to which on the first two days cresol (1 ounce to an ordinary sized bath) and an alkali (a handful of sodium or potassium carbonate) are added; on subsequent mornings the cresol is omitted. After the morning bath, and again in the evening, the following ointment is applied to all affected parts from the neck downward, excepting the genitals:

℞	Chrysarobinae		66
	Acidi salicylici	1	
	Phenolis		66
	Zinci oxidi	6	
	Lanolini et petrolati	āā 30	

Throughout the period of treatment a suit of pajamas is worn next the skin night and day, and thus becomes thoroughly impregnated with the ointment. The patient is inspected by the medical officer at least every second day.

As a rule, the ointment is well tolerated, but, should any area of skin become acutely inflamed and tender, the application of the ointment to that part is at once discontinued, and, instead, some soothing preparation, such as Lassar's paste (to which a little ichthyol may well be added), is kept thickly applied to the affected region. The genitals are throughout protected by Lassar's paste. At the end of a week, sometimes earlier, the eruption in most cases is to a large extent cleared, whereon Lassar's paste, containing 10 grains of salicylic acid to the ounce, is applied to the treated parts, to allay irritation and assist desquamation. A clean suit of pajamas is at the same time issued to the patient, and at this stage a bath on alternate days only is given.

Resistant patches are commonly seen on the elbows and knees, wrists and hands, in the hollows just behind the great trochanters, and sometimes elsewhere. In the treatment of these a stronger ointment is employed as follows:

℞	Chrysarobinae	1	33
	Acidi salicylici	1	66
	Phenolis		66
	Zinci oxidi	6	
	Lanolini et petrolati	āā 30	

This is rubbed well into the patches twice daily, and is also kept applied to them on lint during the night, providing the healthy skin immediately surrounding them is not actively inflamed. In order to prevent the occurrence of conjunctivitis the chrysarobin ointment is not used on the scalp and forehead. The hair is cut very short and the scalp shampooed three times a week. An ointment of the following composition is kept applied by means of lint, or, better, a closely fitting linen cap:

℞	Acidi pyrogallici		66
	Acidi salicylici	1	
	Phenolis		66
	Unguenti hydrargyri oxidi flavi	30	

As a rule, psoriasis of the face and front of the neck will yield to zinc ointment containing 10 grains of ammoniated mercury and 20 to 30 grains of salicylic acid. In more resistant cases the pyrogallic acid ointment, as recommended for the scalp, has proved effectual.

Internal treatment is only adopted in certain cases. Florid persons with an inflamed eruption are kept for a time on a milk diet, with plenty of fluids, and freely purged, and a mixture containing vinum antimoniale and potassium citrate is prescribed thrice daily. In another class of patient there is evidence of intoxication from some septic focus—frequently, apparently the mouth. In these cases a thymol mouth wash is directed to be used several times a day, the sockets of the teeth are cleansed with hydrogen peroxid, the bowels are kept well opened, and a mixture containing dilute hydrochloric acid and nux vomica is given after meals.

Very acute cases, and those in which the eruption is inflamed and angry looking, should not be treated at once with the chrysarobin ointment. Free purgation and diuresis, a milk diet, and the administration of vinum antimoniale, together with the local application of Lassar's paste, containing salicylic acid and ichthyol, form the lines along which treatment should first be directed. When the acuteness of the eruption has subsided the method of treatment already described may be cautiously begun. No patient who is suffering from boils or other forms of pyodermia should begin the treatment until these have been cured; otherwise very acute dermatitis is apt to be provoked.

As seborrheic subjects are peculiarly susceptible to all forms of external irritation, the treatment of psoriasis in them must be carried out under very careful supervision in order to avoid chrysarobin dermatitis. The following alkaline citrate mixture is very useful in these cases: sodium citrate, 30 grains, potassium carbonate, 15 grains and 15 grains of sodium bicarbonate thrice daily one hour before meals.

19. **Cardiac Disabilities of Soldiers.**—The results of an inquiry into the cardiac and circulatory conditions of 5,000 soldiers who were sent to a base with the diagnosis of "V. D. H." (valvular disease of the heart) and "D. A. H." (disordered action of the heart) are detailed by Hume. All these cases were admitted to a convalescent camp, and on admission a history was taken and a physical examination was made. At the first examination, 8.3 per cent. of patients were found to be suffering from easily recognizable diseases which were in no way circulatory in origin. The remaining 91.7 per cent. of patients complained chiefly of breathlessness, pain in the chest, palpitation, giddiness and other less easily definable symptoms. This entity has been described as the soldier's heart, the irritable heart of soldiers, and in the army nomenclature as disordered action of the heart. In this group are fifty-five cases of organic disease of the heart, in which are included three cases of paroxysmal tachycardia. One hundred and sixty-nine had been sent with a frank diagnosis of valvular disease of the heart, though in only fifty-five cases was there any justification for such an opinion. Hume says that the proneness to make a diagnosis of organic disease of the heart seems to be due to the misinterpretation of *systolic murmurs heard in the region* of the heart, and especially at the apex. If a systolic murmur in the region of the apex is due to a leak at the mitral valve, there is almost invariably an alteration in the size of the heart, in the position of the apex beat, and in the intensity of the pulmonary second sound. Hume asserts that a systolic murmur without the accompanying evidences of dilatation and hypertrophy of the heart can be disregarded.

Of the patients with obvious valvular disease of the heart, 56.3 per cent. had suffered from rheumatic fever. Into the same category fall many who are convalescent from infectious diseases, namely, the enteric group of fevers, influenza and *trench fever. In the tachycardia following shell* shock and in neurasthenics the fault lies in the nervous innervation of the heart rather than in the heart muscle itself.

No matter how the condition may be produced, the rationale of treatment is the same in all cases. The most important factor in all cases is the abolition from the patient's mind of the idea that he has a diseased heart. Good food, undisturbed sleep and outdoor exercise, regulated and under discipline, are the sole factors necessary for the improvement of all types. By this method 50 to 60 per cent. can be sent back to their original work after four to five weeks. The remaining 40 to 50 per cent. are unable by reason of poor physique, actual disease, or of age to undertake every kind of work and hardship. Apart from those who suffer from actual heart disease or some organic disease of other systems, nearly all are fit for some service in France.

20. **Delayed Primary Suture of Wounds.**—The term "delayed primary suture" the authors have applied to all cases of suture performed in the first five days after infliction of the wound, with the exception of those closed at the preliminary cleansing operation. It is a suture performed before the full development of granulation tissue and before complete establishment of the natural defenses of the body by active immunization. Of 290 consecutive gunshot cases, thirty-six were sutured within five days of being wounded. Five of these were not up to suture standard and were closed tentatively. The remaining thirty-one cases, 10.7 per cent. of the whole series arrived at the base up to suture standard. Of these thirty-one cases, twenty-eight made a perfect recovery being healed on an average of 10.5 days from the date of suture. The remaining three cases were partially successful. Carrel's bacteriologic standard was of the greatest value in the choice of wounds for delayed primary suture. Morrison and his associates remark that the importance of *suture précoce* cannot be overestimated. At no period is a wound so easily closed as it is before the onset of cicatrization and fixation of tissues in abnormal positions. Not only does closure of a wound obviate the danger of secondary infection and the expense and pain of many *dressings,* but leads to the quickest and most perfect restoration of function. To be able to close wounds of soft parts and *to* convert compound into simple fractures is the ideal of military surgery. That this has been attained in 10 per cent. of cases recently arriving from the front the authors *believe* is a tribute to the work of the casualty clearing stations.

27 *Dilatation of Stomach from Atony. L. Timbal.—p. 481.
28 *Appendicitis in the Gassed. F. Moutier.—p. 493.
29 *Physiology of Rectum. Friedel.—p. 505.
30 *Chronic Inflammation of the Intestines. A. Mathieu—p. 515.

27. **Dilatation of Stomach from Atony.**—Timbal insists that hypersecretion in the fasting stomach is not necessarily a sign of ulceration. It may be a consequence merely of atonic dilatation. The resulting motor disturbances and stagnation of stomach contents irritate the walls, and secondary Reichmann's disease follows. As the motor functioning returns to normal, the secretion becomes more regular. Contrary to the hypersecretion with ulcer, with dilatation the hypersecretion is always pure at first, without admixture of lactic acid. The hypersecretion with dilatation from atony does not require direct treatment. What is needed is to overcome the atony. These patients are debilitated, thin and nervous, and should be treated on this basis. As they become better nourished and stronger, the atony subsides, and along with it the tendency to hypersecretion.

28. **Appendicitis in the Gassed.**—Moutier says that in addition to the ulcerations that have been noted in esophagus, stomach and upper bowel from the toxic action of chlorin gas shells, he has witnessed a number of cases in which the appendix evidently shared in the lesions. He describes six cases in detail in which the appendix had been previously supposedly sound, and three in which there had been a previous suggestion of appendix mischief. The "incubation" was five to eight days in the first group, and twice this or more in those with old lesions. The symptoms did not indicate serious disturbances, and they subsided under local applications. He does not attempt to decide whether the appendicitis is the result of swallowing some of the gas or of a general toxic action.

29. **Physiology of Lower Intestine.**—Friedel's research was on the sigmoid flexure and rectum. He studied the sensibility, motor function, secretion, absorption and the act of defecation. He emphasizes the importance of gases for the act of defecation, although in some persons they are always absorbed before reaching the anus.

30. **Chronic Catarrhal Inflammation of the Intestines.**—This article, found among Mathieu's papers after his death, is a review and comment on Crämer's book with this title published in 1914. He takes issue with Crämer in a number of points.

31 *Walled-in Meningitis. M. Acuña and A. Casaubon.—p. 169.
32 Insular Sclerosis in Youth. P. Gautier and C. Saloz.—p. 199.
33 Hypertrophic Stenosis in Infants. J. Comby.—p. 205.

31. **Walled-in Meningitis.**—This is not a good translation of the original title, "Formes cloisonnées et ventriculaires à cavité close de la méningite cérébro-spinale epidémique," but it expresses the main feature of the cases, the lesion inside the ventricle, without communication with the rest of the skull contents and spinal cavity. This form has been described in adults, but this article is devoted to its occurrence in infants and young children. There may be several walled-in foci and ordinary serotherapy does not reach them. In one of the various cases described, necropsy showed besides the walled-in suppuration in the ventricles, adhesions along the spinal meninges, with formation of isolated pockets of suppuration. Lumbar puncture was repeatedly negative. The anatomic conditions in young infants favor this development of the disease in isolated foci, as the openings for communication are proportionately very small and easily become plugged by the purulent secretion. The meningitis in infants is liable to develop insidiously and escape recognition for some time. This prevents early effectual serotherapy. By the time the serotherapy is begun, adhesions have already developed and closed cavities resulted. The lumbar puncture fluid then grows more and more limpid and scanty, while the general condition and signs of intracranial pressure are growing worse—the reverse of the usual course. The serum injected into the spinal canal is not absorbed. An instructive reflex phenomenon follows intravenous injection of 0.5 to 1 c.c. of the serum. In from ten to thirty minutes symptoms develop suddenly suggesting an anaphylactic shock, congestion of the face and disordered respiration and heart action. All this subsides in four or five minutes; it might be explained by the sudden congestion induced by the intravenous injection raising the pressure in the floor of the fourth ventricle. All the protracted cases of epidemic meningitis are probably of this walled-in type. The antiserum should be injected into the ventricles as well as into the spinal cavity. Seven instructive cases are described in detail in infants from 2 to 28 months old, with the necropsy findings in six cases. The effect of the intraspinal serotherapy was prompt and satisfactory, but it had no action on the disturbance in vision in the one child that did not die.

40 Frame for Lifting the Wounded in Bed. L. Bois.—p. 763.
41 *Conclusions Adopted by Third Interallied Surgical Conference.

37. **Shortening the Sound Femur to Match.**—Calvé and Galland have worked out a technic which gives the maximum of security and precision for shortening the sound mate to correspond with a limb shortened by disease or a war fracture. The sound femur is sawed transversely and then the end of each stump is cut off slanting except that the lower stump has a piece left at the higher end of the slant. The outline of the part cut out is thus a triangle. The part left serves as a tenon to fit into the other slanting stump which serves as the mortise, a corresponding inset having been cut out of the second stump. The two stumps thus fit solidly together and hold firm against pressure from any direction. The sawing of the slant is done with a small circular saw, run by Albee's electric motor, and the tenon is cut with an arrangement of two very small twin saws, the distance between being the desired width of the tenon. The leg is then placed in a plaster cast which includes the pelvis and base of the chest with a strap over the shoulder. Their roentgenograms show that the results were extremely satisfactory in a boy of 13 with a shortening of the leg from an old tuberculous process. The anatomic condition entailed a shortening of 6.5 cm., and the vicious attitude additional shortening of 5 cm. Osteotomy was done on the crippled limb and the sound femur was shortened by the above technic. The difference between the length of the legs is now only 1.5 cm.

41. **Conclusions Adopted by the Interallied Surgical Conference.**—This conference was held last November to discuss treatment of osteomyelitis, fractures of joints, remote results of treatment of fractures of long bones, complications of skull wounds, and thoraco-abdominal wounds and wounds of nerves. In regard to fractures of joints, the trend was toward the maximum of conservation; defective functional results can be treated by orthopedic resection later. Fractures of the femur were said to give only mediocre results on account of the usual extent of the wound, inadequate reduction and contention plus infection. Primary suture is giving much better results. On the whole, the transformation of chemical into mechanical sterilization of the wound is gaining ground more and more as the war progresses. The disappointing results of operations on nerves were ascribed to the usual long delay before the operation is done, but at the same time it must not be attempted while there is any suppuration. The conference also modified some of the conclusions that had been adopted at the preceding conference. The primary suture

then was regarded as only exceptionally indicated, but it is said now to be the general method of treatment.

The advisability was suggested of holding a conference of bacteriologists to determine exactly which germs are most to be dreaded with the primary or postponed primary suture. To date, the streptococcus and the spore-bearing anaerobes are incriminated and possibly the proteus. Alkaline treatment of the acidosis with gas gangrene has given encouraging results. Some patients have been given specific serotherapy, antiperfringens, etc. The latter seems to have aided in warding off gas gangrene in certain cases, given as a preventive. The treatment of shock has also been modified to conform to the three processes involved, the hemorrhage, the infection or intoxication, and the true shock. The number of red corpuscles in the venous blood during the first few hours after the wound reveals whether there has been much hemorrhage from the wound on the limb. Transfusion is useful here. In true shock, heating the bed is the main thing. English surgeons advocate intravenous injection of 500 c.c. of a 4 per cent. solution of sodium bicarbonate. No other saline solution has given conclusive results to date. The conference emphasized the immense progress realized in treatment of fractures by adoption of a unified plan.

43. **Benzene in Treatment of Leukemia.**—Vaquez and Yacoel report three cases of leukemia which confirm anew the favorable action of benzene (benzol, C_6H_6) in this disease. They tabulate reports from eleven other clinicians, all showing improvement in the general health, and reduction in the size of the spleen and in the numbers of leukocytes, while the numbers of reds increased. The most striking change was in the patient of F. Deutsch whose whites dropped from 836,000 to 7,000, but Frank Billings has reported a case not far behind this. Even with a pathologic increase in the reds, the benzene has likewise a regulating effect, but its leukolytic action is so pronounced that when given in the dose sufficient to reduce the reds from 8 to 6 millions, it reduced at the same time the whites down to 1,200. The leukocytes of normal persons are quite resistant to the benzene, comparatively speaking. Given parallel to a healthy person and to a patient with leukemia, the whites in the former dropped from 7,800 to 3,000 while in the leukemic it dropped from 800,000 to 16,000. They begin by giving 40 drops of benzene a day, increasing to 100 drops by the fifth day. This is continued during the first twelve days of each month, examining the blood every week and watching over the urine likewise. If the leukocytes are being destroyed too rapidly, the drug should be suspended for a fortnight. They give the benzol in capsules or in wine or milk. Given in this way it can be kept up for months. A supplementary course of radiotherapy may be useful. They alternate the courses of each. The patients in the cases reported were a man and a woman of 50 and 51 and a young soldier. The stimulating effect on the blood-producing organs is shown by the drop of whites from 525,000 to 15,000 in one case seven weeks after the benzene had been begun, while the hemoglobin has reached 75 per cent. and the reds gone up from 3,500,000 to 5,000,000. After this the whites ranged between 8,000 and 12,000, and the general condition has kept satisfactory.

44. **Rat-Bite Disease.**—Two typical and two abortive cases of rat-bite disease are described, all with the characteristic long incubation, two, three or four weeks after the bite of the rat, then the lymphangitis, adenitis, induration of certain muscles, more or less extensive exanthem, and attacks of fever. Sometimes the fever is very high, but it does not last long, and the attacks are separated by about five days of complete apyrexia. The lymphangitis drags along for more than a month. Bacteriologic examinations were negative, and no effect was apparent from the usual antipyretics. No attempt was made to give arsphenamin, although this has proved successful in certain cases on record. The five-day periodicity of the fever suggests the "five-day fever" of the Germans.

46. **Cardiac Manifestations of Scarlet Fever.**—Florand and Paraf report complications on the part of the heart in fourteen out of twenty-seven scarlet fever cases during a recent brief period. The mitral valve was the one affected; the aorta did not seem to be involved. In four cases the valvular lesion persisted in a chronic form; in the others all signs of the heart complications disappeared, leaving merely palpitations and instability of the pulse. De Massary, in the discussion that followed, said that in his latest series of 355 cases of scarlet fever in soldiers, there was nothing to suggest that either the endocardium or pericardium had been affected, except in those who presented signs of established heart or vascular disease when first seen. He has encountered a typical case of aortic insufficiency developing in the course of scarlet fever in a young woman and persisting to date, but in his experience such complications are rare. In the series of scarlet fever cases in the military hospital, a few of the men complained of pains suggesting rheumatism, but they always yielded promptly to sodium salicylate. The arterial pressure was always high, but there were few cases of renal complications; only two cases of early and transient hematuria and seven cases of tardy and tenacious albuminuria. No special treatment was given, merely rinsing the throat and gargling often with sodium bicarbonate, two teaspoonfuls to the liter, and three times a day a medicated oil was instilled into the nose; restriction to milk for ten days, then milk and potato purée, then vegetables, and the full diet the last ten days. Netter told of a case of severe scarlatinal myocarditis in which epinephrin internally had resulted in an absolutely unanticipated cure. Epinephrin, he remarked, renders incomparable service in such cases. Complications on the part of the heart are rather frequent in children. They generally coincide with joint complications and sometimes with chorea.

53 *Anaerobic Gangrene of Bladder. F. Legueu.—p. 105.
54 *Military Aspect of Stricture of Urethra. O. Pasteau.—p. 117.
55 *War Wounds of Kidneys. P. Noguès.—p. 123.
56 *Cancer of Kidney. R. de Berne-Lagarde.—p. 135.
57 Calculus with Stricture of Urethra. Maringer.—p. 143.
58 War Wounds of Urethra. Hourtoule.—p. 147; Rousseau.—p. 149.
59 *Extraction of Hairpin from Bladder. F. Legueu.—p. 151.
60 *Conference of Army Urologists.—p. 155.

53. **Anaerobic Gangrene of Bladder.**—Legueu's patient had retention of urine two days after an operation for extraction of shrapnel balls in buttocks and pelvis. The daily catheterization set up anaerobic gangrene and thick pus was rinsed out. When the bladder was opened, what was supposed to be omentum, covered with calcareous concretions, presented in the opening in the bladder, and a rupture of the bladder was assumed. But when this thick tissue was lifted up, it proved to be a loose sac, the inner lining of the bladder. As it was lifted out, the stench was terrible. The vessel walls were thick and red but did not bleed, and under frequent lavage with tepid oxycyanid the bladder gradually returned to normal size. Recovery was afebrile, but one kidney later required nephrotomy. Certain symptoms now suggest incipient disease in the other kidney. Legueu incriminates the catheter required for the accidental retention of urine as responsible for the introduction of the anaerobes.

In another case a woman at the eighteenth day of mild typhoid developed signs of infection of the nervous system, with retention of urine. Eight days after the beginning of the urine trouble, what seemed to be a false membrane protruded from the urethra. Legueu was able to extract it through the urethra and it proved to be a sac, the cast off inner lining of the bladder, studded with calcareous concretions. The woman is recovering and micturition is normal, but there was incontinence of urine for ten days. He cites a few cases of this desquamating gangrene on record. The retention has always been regarded as responsible for the distention, but its rôle is indirect, as it acts only by compelling catheterization. He isolated from his latest case Jungano's anaerobic *Bacille neigeux*. The mucosa has rapidly regenerated in the cases on record, but incontinence is liable. The soldier still is wearing a urinal six months later, this false incontinence being the result of the small capacity of the bladder. Ascending pyelonephritis is liable to develop at any time.

54. **Urethral Stricture from the Military Standpoint.**—Pasteau advises that in all cases in which the complications are the predominant feature, the men should be sent to hospitals in the home zone for treatment. Stricture without severe complications should be treated in the genito-urinary special centers with the army, or in the interior, if the stricture can be overcome with progressive dilatation or urethrotomy. If not amenable to this treatment, the men should be transferred to the auxiliary service or dismissed. Men with stenosis of the posterior urethra (fracture of the pelvis), are unfit for any military service.

55. **War Wounds of the Kidney.**—Noguès discusses what should be done at the advanced surgical station for war wounds of the kidneys.

56. **Cancer of the Kidney.**—Lagarde describes in detail a case of epithelioma developing in a kidney subject to hydronephrosis. Hematuria was the first symptom, and nephrectomy was done in two months, with smooth recovery.

59. **Extraction of Hairpin from Bladder.**—Legueu slips a long hook, something like a buttonhook, through the cystoscope arranged for unilateral catheterization. As the hook seizes the hairpin and pulls on it, the hairpin swings around to present its rounding end to the hook, and it is easily removed.

60. **Conference of Army Urologists.**—The two subjects of the addresses and discussions were war wounds of the bladder and urethra, and what should be done for soldiers with incontinence of urine. The conclusions adopted favored emergency cystostomy for wounds of the bladder or urethra. The principle of primary suture cannot be applied in these cases. Incontinence of urine requires examination by a specialist. The man should be given treatment for not longer than two months. If the general condition is good and the incontinence is found to be incurable, at least within two months, the man should be sent back to the ranks. The conference emphasized the importance of specialist centers where the men with urinary disease can be sorted out, and those that can be treated there retained, and the others sent back to the interior. The necessity for keeping records of the health and hospital history of each man in the force was also emphasized. The diagnosis and the treatment should be recorded, and the case history should go with him or follow him to each hospital he enters.

March, 1918, **127**, No. 3

61 *Radium in Gynecology. R. Condamin and L. Nogier.—p. 97.
62 *"Mustard" Gas. R. Rendu.—p. 108.

61. **Radium Therapy in Gynecology.**—Condamin and Nogier give the details of six cases which show the great advantages of radium treatment in its own special field, namely, for inoperable and recurring uterine cancer, for fibroma when an operation is inadvisable, and also preliminary to or following operative measures. They state that war conditions have evidently cooperated in allowing uterine cancers to get beyond the operable stage before they reach a physician. Since 1914 they have applied radium therapy in 500 cases of this kind. In one case an abdominal tumor reached two fingerbreadths above the umbilicus, in a girl of 12, with extreme cachexia and retention of urine. Under forty-eight hours of application, the radium in the center of the growth, the tumor disappeared completely and perfect health was restored. The total dose given was 24.03834 millicuries. No microscopic examination was made of the neoplasm tissue, as a complete necropsy in a short time was confidently expected. The tumor was undoubtedly malignant and originated in the ovary. It was as large as the child's head. The condition grew graver during the first two or thre weeks after the exposure, evidently from absorption of toxins. This confirms the wisdom of removing all that can be easily removed of an inoperable tumor before applying the radium. In some of the cases reported this was done so effectually that there was no nausea, fever or other sign of toxic action after the exposures. In a case of inoperable cancer of the uterine cervix in a woman of 50, the cure has been complete for three years to date. The patient has complained at times of slight pains in and around the uterus, but there is no sign of recurrence, and the pains are probably from compression of some nerve fibers in the scar tissue. In this and similar cases, the whole of the uterus has atrophied so completely that there is no need for the proposed hysterectomy. One disadvantage of preoperative radium treatment is that the patients feel so much improved, that they then withdraw their consent to an operation. A week after hysterectomy, in another case, radium was applied to the sound tissue left, and a severe toxic, febrile reaction followed, showing that the by-effects of radium occur with sound as well as with diseased tissue. In one woman of 36 the cancer returned three years after hysterectomy, but the recurring tumor disappeared under radium treatment, and there has been no further sign of malignant disease during the nearly three years to date.

62. **Effects of "Mustard" Gas.**—Rendu describes the lesions induced in the upper air passages by the new *gaz vésicants* used by the Germans. They are all practically alike, resembling a burn of the second degree, and leaving white eschars. The latter are most frequent on the anterior two thirds of the free margin of the vocal cords.

Nourrisson, Paris

March, 1918, **6**, No. 2

63 *Roentgen Aspects of Rachitis. E. A. Weil.—p. 65.
64 Mercuric Lactate for Syphilitic Infants. A. B. Marfan.—p. 86.
65 Arresting the Decline in the Birth Rate. E. Apert.—p. 94.
66 *Glycuronuria in Infants. R. Raimondi.—p. 104.

63. **Roentgen Findings in Rachitis.**—Weil remarks that the lesions of rachitis are best studied, usually, on the wrist and hand or on the knee, as he describes in detail, with eighteen illustrations. He emphasizes in particular the opaque border of the end of the bone next the cartilage, *le signe de l'os bordé*, early in rachitis. This indicates that ossification is more intense here, while the rest of the bone shows decalcification. The ends of the shaft also spread out broad, or show a mushroom-like protuberance on the end, or they cast a cupule-shaped shadow. In advanced cases there may be two or four dark strips in the end of the shafts. When rachitis is acquired near puberty, the roentgen findings resemble closely those in young rachitic children. The roentgen findings with osteomuscular dystrophy and tendency to stunting of the growth differ from those of rachitis. In a case of tendency to dwarfism of this type, he applied moderate roentgen treatment to the ends of the long bones. The boy of 11 had shown no sign of growth of the bones for several years. The ossification in his knees was no farther advanced than in a normal child of 5, and the shadows closely resembled those of early rachitis. The growth was accelerated by the roentgen exposures.

66. **Glycuronuria in Infants.**—Raimondi extols the determination of the glycuronic acid in the urine of infants as a simple, easy and rapid test for estimating the functioning of the liver. With hypoglycuronuria the food should be changed and measures taken to stimulate liver functioning (calomel, opotherapy, alkalines and camphor). These conclusions are based on the study of the urine of twenty-one infants, healthy.

Boletin de la Asociacion Medica de Puerto Rico, San Juan

March, 1918, 14, No. 118

79 *Anaphylatoxin and Anaphylaxis. F. G. Novy and DeKruif. —p. 175.
80 *Pituitary Extract in Obstetrics. D. P. Marchand.—p. 186.
81 Magnesium Sulphate in Tetanus. M. Janer.—p. 190.
82 Ether or Chloroform J. S. Belaval.—p. 194.
83 Stab Wound of Lung. A. Santaella.—p. 200.
84 *The Cancer Question. J. del Toro—p. 202.
85 *Cancer as Problem of Social Medicine. J. Aviles.—p. 207.

79. **Anaphylatoxin and Anaphylaxis.**—This is mostly a translation of Novy's work published in The Journal, May 26, 1917, p. 1524.

80. **Abuse of Pituitary Extract in Obstetrics.**—Marchand relates that the midwives in her district have learned to appreciate the potent action of pituitary treatment, and they are using it blindly in all kinds of obstetric cases. Delivery is accompanied by lacerations and other complications from this routine use of pituitary extract. She urges restriction in its sale, as it is a weapon too dangerous for the hands of ignorant midwives. In a recent case, she was called to a primipara who had been given four injections of the pituitary extract. The woman was moribund, lying in a pool of blood, the inverted and relaxed uterus exposed to view. In a second similar case Marchand had time to reduce the uterus and combat the collapse following the terrific hemorrhage. This primipara had been given three injections when the cervix had barely begun to open. In these cases the judicial reprimand of the midwife did not help her victim. Even in skilled and experienced hands, pituitary extract must be handled with caution, respecting its still unknown total effects. Restrictions have been imposed by the Harrison law on the sale of narcotics, and she urges similar safeguards against certain other dangerous drugs now used freely.

84. **Cancer in Porto Rico.**—Del Toro states that cancer has formed from 1.09 to 1.35 per cent. of the total mortality of the island since 1912. In the public hospital there have been 151 cases of cancer since its opening in 1909; the growth was inoperable in almost 50 per cent. Only 12 per cent. of the cases were in a promising condition for operation. The uterus was the seat of the malignant disease in over 33 per cent.; the mamma in about 8 per cent. He warns that even physicians are not always insistent enough for a prompt operation; they are liable to delay for absolute certainty, or to try this or that treatment, or they send the patient to the continent for radium treatment. He emphasizes that the progress of surgery has deprived it of so much of its dangers that an operation should no longer be reserved for a last resort, and he warns that to wait for the classic symptoms of malignant disease dooms the patient.

85. **Cancer and Social Medicine.**—Aviles quotes some figures to the effect that while 659,528 persons died in the Civil War, there were 1,021,513 deaths from cancer alone in the United States between 1900 and 1915. There is a death from cancer every six and a half minutes. In Porto Rico during 1915 there was one death from cancer every day, and in the city of San Juan last year three deaths every month. In 1890, Agnew of Philadelphia declared that there never had been a case cured of mammary cancer, but Halstead the same week operated on a patient who was entirely free from cancer when examined in 1913. Fully 60 per cent. of the deaths from cancer might have been avoided. Aviles urged the medical association to cooperate with the Public Health Service to publish circulars to educate the public, with lectures for those who cannot read or do not get the circulars. He also advocated frequent discussion of cancer problems to disseminate all that can be learned on the subject. He added that it would be a good plan for women's clubs to be enlisted in the work of educating the public in respect to cancer, and getting the press to aid the propaganda.

87 *Gangrene from Arterial Obstruction. Blanc y Fortacin.—p. 19.
88 Ulceration from Mortification of Tissues. Sicilia.—p. 199.
89 Influence of Gouty Tendency and Endocrine Disturbance on Heart Disease. Huertas y Barrero.—p. 222. Continuation. p.

86. **Pityriasis Rubra Pilaris.**—De Grado's experience with the case described confirms the assumption that the tubercle bacillus has something to do with this disease. Under diagnostic injections of tuberculin the lesions showed a typical response, and under tuberculin injections and application of 4 per cent. salicylate salve great improvement was realized in the young man.

87. **Arterial Gangrene.**—In Blanc's case the gangrene from obliteration of an artery was too far advanced for any treatment except amputation. The site for the amputation was decided by applying an Esmarch band. After its removal the blood rushing into the limb colored it pink in all the regions where the blood circulated. The line where the tint remained unmodified was the limit of sound tissue. In another case of incipient gangrene he had fair results from anastomosis between the artery above the obstruction and an adjoining vein. This transformed the vein into a kind of artery. It became dilated and the aspect of its wall changed to resemble an artery wall. The central stump of the vein was ligated above.

January, 1918, 1, No. 1

90 *Plague Pseudo Tuberculosis. S. Dessy.—p. 5.

90. **Plague Pseudotuberculosis.**—Dessy reports the case of a working man of 26 who died eighteen days after the physician had been called on account of symptoms ascribed to typhoid fever. Necropsy showed, however, that the intestines were free from ulceration while the liver contained numerous nodules resembling those found in rats with plague; the lungs presented the aspect of miliary tuberculosis. If it had not been for the nodules in the liver, the case would have been recorded as a matter of course as miliary tuberculosis. But the microscope revealed in six hours the presence of the plague coccobacillus in the condensation water of agar tubes inoculated with material from the lungs and liver. Inoculation of laboratory animals confirmed the diagnosis. The histologic findings are reproduced. They suggest that the infection occurred by way of the intestines, passing thence in the blood to the liver and lungs. The nodular lesions show that the plague bacteria in question were not very virulent for the human organism, although they induced plague septicemia in white rats and guinea-pigs, fatal in forty, fifty-six or seventy-five hours.

Semana Medica, Buenos Aires

Jan. 17, 1918, 25, No. 3

91 General Principles for Vaginal Operations. A. Chueco.—p. 65.
92 Provisions for Care of the Sick and Poor at Buenos Aires. E. R. Coni.—p. 79. Continuation.
93 *Retrocursive Epileptic Seizures. G. Mingazzini.—p. 88.

Jan. 24, 1918, 25, No. 4

94 *Suprarenal Hematoma. F. A. Deluca.—p. 93.
95 Deafness in Schoolchildren. A. Quadri.—p. 97.
96 Symptoms and Findings with Mole. J. C. Berri.—p. 103.
97 *Suprarenal Form of Malaria. C. Fraga.—p. 113.

93. **Retrocursive Epilepsy.**—Mingazzini applies this term to epileptic seizures in which the motor phenomena are almost exclusively merely stepping backward. In another type of seizure there is a tendency to run in a circle. He describes the case of a boy of 8 with this retrocursive epilepsy. The boy feels first formication in the left hand, then loses consciousness, and steps backward on a straight line for 3 or 4 meters, and then falls with general clonic spasm. He has been having from ten to fifteen of these seizures a day for the few months.

renal **Hematoma.**—Deluca reports two cases of
th child stillborn or dying the fifth day,
a suprarenal hematoma in each child.
born alive had been difficult and
philis was probable. The third

day the child's pallor attracted attention (hemorrhage), then came jaundice, prostration, and screams of pain; the fourth day convulsions and the fifth, sudden death—this sequence of symptoms explained by the hematoma in the suprarenals. The woman in the other case had been given pituitary extract, and there is a possibility, he suggests, that this might have caused such forcible contractions of the uterus as to compress the fetus' abdomen and force blood out from the inferior vena cava.

97. **Suprarenal Form of Malaria.**—Fraga describes three cases of an evident suprarenal syndrome in the course of malaria, with necropsy in one. They confirm his assertion that we must reckon with a *forma suprarenal de la parasitosis tropical,* and be on the alert to apply the specific treatment. In the severer cases, intravenous injections of artificial serum with epinephrin may tide the patient past the danger point. When the emergency is not so great, ordinary opotherapy may answer the purpose.

98 Reform in Medical Education. V. Prieto.—p. 82.
99 *Endemic Goiter in Spain. J. Goyanes.—p. 85.

99. **Endemic Goiter in Spain.**—In this instalment of his study of the endemic foci of goiter in the mountain districts of Spain, Goyanes calls attention to the frequency of deafmutism among the families with goiter. Cretinism is common, but exophthalmic goiter is extremely rare. He has photographs of one family in which two of the daughters of a woman with goiter are deafmutes. He has seen a number of deafmutes with goiter in the district of Avila, and also deafmute cretins. The antecedents always showed goiter in the mother or father or grandparents of the cretins.

Nederlandsch Tijdschrift voor Geneeskunde, Amsterdam

100 *Radioactive Balances. H. Zwaardemaker.—p. 602.
101 *Measures against Plague in Holland. M. A. van Andel.—p. 614.
102 *The Recording of Nystagmus. H. J. L. Struycken.—p. 621.
103 Unilateral Paralysis of Phrenic Nerve. J. Hekman.—p. 625.

100. **Radioactive Balances.**—Zwaardemaker reports here further research on the living isolated frog heart perfused with Ringer's solution made with some radioactive salt in the place of the potassium of the original Ringer solution. There seems to be an antagonism between the action on the frog heart of the radioactive light metals and the radioactive heavy metals. Research in this line has elicited a number of new biologic facts as he describes in detail. Among them is that fluorescein seems to sensitize the heart so that a smaller amount of the radioactive salt has a greater effect than a large amount without it.

101. **Prophylaxis of Plague in Seventeenth Century.**—Van Andel gives the instructions issued by the "plague-master" of Gorinchem in 1601. The plague-master was given a good salary, the records show, and the authorities sustained him in his efforts to check the disease and alleviate the condition of the sick.

102. **Recording Nystagmus.**—Struycken obtains a record of the movements of the eye by photography, using a delicate wire tripod that fits over the eyeball. This shows on the film drum the various types of the nystagmus, horizontal, vertical, undulating, rotatory, circular, etc.

104. **The Nervous System with Spondylitis Deforma**on-
Malling remarks that it is still a question whether the lungs forms of chronic spondylitis are separate enti and reports one seems to have studied the slighter with a similar mild deforming spondylitis, and as a con; two cases in which tabulates the findings in twenty-

years old. In none of them had there been any noticeal deformity of the spine or pronounced nervous symptoms du ing life. In eighteen of the cadavers there were evidences more or less severe spondylitis, and in two the findings we dubious. Thus only five of the total number were free fro exostoses, and none of these were over 50, and only one wa a man. He could not find anything to suggest that the exostoses developed inwardly and thus injured the spina cord or nerve roots. It is possible, however, that in certai cases, pain, sciatica, etc., may be the result of pressure the nerve at the root. It is a tempting explanation of certa nervous disturbances, such as spastic paraplegia, to assum pressure on the nerve roots by these changes in the vertebr which are practically constant after a certain age in workin people, but Malling warns that this will often lead one on t wrong track.

112 *Orthostatic Albuminuria. V. Scheel.—p. 385.
113 Mania in Deafmute. A. Wimmer.—p. 395.

109. **Roentgen Treatment of Brain Tumors.**—Nordentoft now has a record of twenty cases of brain tumors in which he has applied systematic courses of roentgen exposures. The results are quite encouraging, especially when compared with the 100 per cent. mortality of operative cases of cerebellar tumors in the Scandinavian countries. There is only one case known in Denmark in which a tumor elsewhere in the brain was successfully removed with long survival. He describes his technic and the findings and results in his twenty cases. The favorable experiences in his first series of eight cases have continued to date; there has been no recurrence of the growth or return of symptoms.

110. **Calomel for Pruritus Ani.**—Hamburger has had a number of patients freed from long persisting anal pruritus when they rubbed the region with dry calomel. The part is wiped off first with moist cotton, the finger is moistened, and the powder is taken up on the finger and rubbed into the crevices. The itching generally subsides permanently, or at least for several months, after four or five applications of the calomel.

111. **Safety Match Box Eczema.**—Four writers in turn describe cases of a dermatitis which they were unable to explain in the otherwise healthy patients until they learned of Rasch's experience with local poisoning of the skin from the use of a certain brand of safety matches (Jönköping). In most of them the burnlike dermatitis was on the thighs, corresponding to the trousers pockets in which they carried the match boxes. Rasch's communication on the subject was summarized on page 1344.

112. **Orthostatic Albuminuria.**—Scheel gives an analysis of fourteen *orthotikers,* as he calls them. All were children at about puberty, except four young men and one woman of 33. All gave a normal response to Strauss' accommodation test ingestion of a liter of weak tea in the morning, fasting, after a day of test diet. Orthostatic albuminuria requires no special treatment, but differentiation is extremely important as otherwise unnecessary restrictions and other measures are imposed for the assumed underlying nephritis. This is particularly disastrous in these cases because persons with orthostatic albuminuria are usually frail; some of his patients ge shown symptoms of tuberculosis since. Another feature he cases is the tendency to oxaluria. He found that the minuria disappeared completely or became much atten- when the oxaluria was arrested by giving a level teaspoonful of calcined magnesia two or three times a day. With nephritis, the albumin content of the urine shows little
